AN

ILLUSTRATED WEEKLY JOURNAL

OF

Horticulture in all its Branches.

Founded by W. Robinson in 1871.

EDITED BY E. H. M. COX.

VOLUME LXXXVIII.—1924

LONDON.

Office: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.

Published by "COUNTRY LIFE," Ltd., 20, Tavistock Street, Covent Garden, W.C., and by GEORGE NEWNES, Ltd., 8-11, Southampton Street, Strand.

Digitized by Google

THIS (THE EIGHTY-EIGHTH) VOLUME OF "THE GARDEN"

IS DEDICATED, BY PERMISSION, TO

GEORGE FORREST, V.M.H.

MR. GEORGE FORREST, who was born in 1873 at Falkirk in Scotland, is so well known as a plant collector in China and Tibet that he requires no introduction to readers of THE GARDEN. In early youth he spent some years in Australia and South Africa, and it was not until 1903 that he considered the profession of plant collecting. In 1904, at the instigation of the late Sir Isaac Bayley Balfour, he undertook his first expedition to Yunnan to collect plants for Mr. A. K. Bulley of Neston.

Between that date and this he has collected over 25,000 plant specimens and has discovered over a thousand plants new to science. This is a significant total and proves Mr. Forrest's zeal and keenness for his work. His various expeditions are: 1904-6, 1910, 1912–14, 1917–19, 1921–22, 1924–. He is at present in Yunnan on his sixth expedition. In 1920 he received the Victoria Medal of Honour from the Royal Horticultural Society, and in the same year the "George Robert White Medal of Honour for Eminent Service in Horticulture" from the Massachusetts Horticultural Society.

What is not so well realised is that, in addition to plants, he has made on each of his expeditions large and important collections of mammals, birds, insects and butterflies.

Although interested in every conceivable kind of plant, his specialities have undoubtedly been rhododendrons and primulas. Of these two families he has introduced many of the finest species to be found in our gardens. So many of our fine garden plants are the result of his labour that it is impossible even to attempt a list, but three samples may be mentioned which all bear his name: these are Rhododendron Forrestii, Primula Forrestii and Pieris Forrestii. He has always believed in the magnificent flora of Yunnan and the borders of Tibet, and even when the greatest botanists in this country were saying that China was finished as a repository of new plants, he stuck to his assertion that where one worthy plant had been discovered there were ten more awaiting the collector.

There is certainly no European who knows more of the mountains of Yunnan and the Tibetan border. No difficulty, danger or hardship is too much for him to overcome. He comes and goes freely and without question in a country which is almost always in a state of turmoil; there could be no better description than that of his character.

We have much pleasure in dedicating this volume of THE GARDEN to one of the greatest plant collectors of all time. Every gardener owes him a great debt of gratitude for introducing so many fine plants to cultivation.

INDEX TO ILLUSTRATIONS

Abies cephalonica, 265; Fargesii, 167; Pinaspo, 265
Acacia armata, 276; Baileyana, 154
Acantholimon venustum, 527
Acer griseum, 816
Adonis amurensis, 263
Æginetia indica, 260
Æonium canariense, 762; sedifolium, 763
Æsculus parviflora, 144
Æthionema pulchellum, 480
Agapanthus, 343
Alchryson pachycaulon, 763
Aldenham, an exhibit from, 318; the gardens, 322; the lily pool, 321; the rhododendron walk, 320
Allium karataviense, 4; macranthum, 5; ursinum, 4
Allwoodii, 401
Aloe, 811
Althæa, 595
Alyssum serpyllifolium, 53; spinosum, 182
Andromeda polifolia, 208
Androsace imbricata, 38, 455; "primuloides," 50; pyrenaica, 345; Wulfeniana, 345
Anemone apennina, 186; nemorosa bosniaca, 189; Pulsatilla, 189; Pulsatilla Madam Van Der Kist, 228; vernalis, 455
Antirrhinums, 279, 280, 659
Apple, Allington Pippin, 23
Apple, an old espalier trained, 326; a too much pruned, 100; exhibit, 716; freak, 10
Aquilegia glandulosa, 375
Arbutus Unedo, 127
Arctostaphylos manzanita, 756
Arenaria balearica, 24; montana, 226; montana grandiflora, 90, 549; purpurascens, 245
Argemones, 820
Arisæma candidissima, 408
Aristolochia elegans, 803
Asparagus, cultivation of, 148
Aster Climax, 676, 766; exhibit, 686; Nancy Ballard, 675
Asters, 496
Astilbe ceres, 747
Aubrietias, 308, 326
Azalea procumbens, 245
Azaleas in the wild garden, 306

Banana plant, a thatch covered, 233
Beech hedge, 349
Begonias, 403; double, 3
Begonia, a typical winter-flowering, 44; manicata, 31; Queen of Whites, 20; Stella, 45
Berberis aggregata, 645; hybrid, 739; japonica, 105; koreana, 645; stenophylla, 34, 350; Thunbergii, 645
Blackbird, 761
Blackspot on rose leaf, 242
Bluebells, 365
Blue tit, 761
Border, 577; end of a sunny, 165
Bougainvillæa glabra, 276
Brasso-Cattleya Cliftonia albeno, 677
Brockhurst, the rock garden at, 82, 83, 84, 85
Bryanthus empetriformis, 833
Budding, Acer, 143
Buddleia alternifolia, 757; auriculata, 325; Farreri, 250; variabilis, 67
Bulbs, Messrs. R. H. Baths' exhibit of, 152
Bullfinch, 774
Buttonbush, 822

Callistemon salignus, 553
Calocephalus, 398
Calystegia sylvestris rosea, 607
Campanula acutangula, 315; alliariæfolia, 515; alpina, 316; lactiflora alba, 515; pusilla, 479; Stansfieldii, 316
Canterbury Bells under glass, 93
Cape pelargonium, 547; Prince of Orange, 546
Carnation Bookham Yellow, 219; Eldora, 247; exhibit, 382, 683; Freddie Ward, 71; Kelso, 220; King of Cloves, 759; Steerforth, 220, 759; Tess, 247
Carpenteria, 420
Castanea pumila, 821
Ceanothus azureus, 544; Gloire de Versailles, 543; rigidus, 421; thyrsiflorus griseus, 544
Cedar at Dropmore, 265
Celery fly, the, 241
Celmisia Armstrongii, 632; verbascifolia, 633
Cephalocereus senilis, 180
Cercidiphyllum japonicum, 873
Chalk pit garden, 467
Chelsea Physic Garden, 509, 516
Cherry, a fan trained, 89; Morello, 300
Chieranthus Allionii, 649
Chionodoxas, 258, 562; Luciliæ alba, 336
Chrysanthemum Alex. A. McAlpine, 297; Brightness, 630; Envy, 809; exhibit, 777, 784; frutescens, 495; Harmony, 777; Miss Dorothy Wilson, 750; Pink Beauty, 629; R. W. Reiman, 47; Sheila, 782; "Ice Cap," 631
Chrysanthemums, Border, at Hampton Court, 298; How to stop, 172
Cineraria, 585; white, 334; white and maroon, 334
Cirque de Gavarnie, 435
Cistus Loretii, 126
Citruses, Messrs. Rivers' exhibit of, 109
Clematis Armandi, 421; Belle of Woking, 694; Grand Duchess, 693; macropetala, 223; The Bride, 693
Clivia miniata, 228
Cornus alba Spæthii, 127; controversa, 321, 537; officinalis, 332, 333; suecica, 773
Corylopsis Gotoana, 419
Cotoneaster, 420, 631; Magnolia, 420; humifusa, 35
Cottage garden, 371, 497, 552
Crocuses, 562
Crocus Imperati, 131; pulchellus albus, 842; Sieberi, 69; speciosus, 843; vernus, 6, 62; versicolor, 567
Cryptomeria japonica Vilmorinlana, 310
Cucurbita ficifolia, 735
Currant, Baldwin Black, 122; Black, and big bud, 171; Boskoop Black, 122
Cutworms, 48
Cyclamen, a white seedling, 290; Giant White Wonder, 191; greenhouse, 101, 102
Cymbidium, a typical hybrid, 161; Pauwelsii, 161
Cynoglossum amabile, 483
Cypripedium Fairrieanum, 312
Cytisus præcox, 393; supranubius, 436

Daboecia polifolia, 800
Daffodils by the waterside, 97, 559, 570; in woodland, 273; planting, at the New York Botanic Gardens, 849
Daffodil Nevis, 287
Dahlia Admiral, 260; cactus-flowered, 680; exhibit, 652, 680; Ideal, 260; White Star, 259
Daphne Blagayana, 183; Cneorum, 160, 440
Davidia Vilmoriniana, 620
Delphinium, a white seedling, 194; Blue Boy, 643; Sir Douglas Haig, 147; Monarch of Wales, 797; The Nymph, 147; F. W. Smith, 147
Delphiniums, 146, 469; seedling, 644
Designs for knot gardens, 610
Deutzia longifolia, 582
Dianthus cæsius, 479; cæsius grandiflorus, 54
Digging, 780
Dimorphotheca aurantiaca, 58
Dipelta floribunda, 583
Donatia novæ-zelandiæ, 633
Dormouse, 729
Douglasia Vitaliana, 244
Dryas octopetala, 303, 549

Edinburgh Laboratory, 535
Edraianthus dalmaticus, 207; Pumilio, 206; serpyllifolius, 207
Enkianthus campanulatus, 429; japonicus, 420
Eranthis × Tubergenii, 109
Erica darleyensis, 79; hyemalis, 627; vagans alba, 449
Erinacea pungens, 456
Erinus alpinus, 226
Eucomis punctata, 733
Eucryphia, a hybrid, 270; Nymansay, 620
Euonymus latifolius atropurpureus, 810
Exochorda grandiflora, 731

Foliage, by the water, 747; beds, 398; plants, 405
Formal garden, 376
Forsythia ovata, 373
Fothergilla major, 55
Freesia Apothèose, 571; Golden King, 571; Mouette, 570; Whitewell, 288
Freesias, Messrs. Sutton and Sons' exhibit of, 267
Fritillaria Meleagris, 49, 257; pallidiflora, 258
Fruit garden, a badly planned, 121; a well planned, 121
Fruit room, 748; packing, 834
Fruit trees, overgrown, 100; grease-banding, 650; pruning, 162, 163; trained, 99
Fuchsia for indoor decoration, 728; macrostemma Riccartonii, 727; procumbens, 324
Funkia tardiflora, 792
Furcræa, 765

Galanthus Scharlocki, 7
Galtonia candicans, 732
Garden, a corner of an old, 157; design, 802; furniture, 484, 485; a walled, 117; in the making, at Wembley, 186, 187; paved, 828; plan, 829; steps, 443; Logan, 602, 603; The Bayley-Balfour Memorial, 598; Bridge End, 388; Gothenburg Botanic, 772; Inverleith, 601; water, 654
Gardenia, 535
Gaultheria procumbens, 833
Genista dalmatica, 201; hispanica, 506
Gentiana, 681; acaulis alba, 17; Farreri, 488; gentilis, 804; sinoornata, 605; verna, 344, 454; verna Chionodoxa, 17
Geraniums, 637; Farrer's Pink, 407
Gladiolus Liberty, 141; Melleri, 71; Nydia, 140; primulinus hybrids, 139; White Giant, 651; Spitfire, 682
Gloxinia, 353; a good type of, 59; exhibit, 683
Gooseberry mildew, 281
Gourds, ornamental, 103, 104
Grafting, the art of, 184
Grass walks, 587
Greenhouses, plans of, 133
Green pea cassolettes, 499; croquettes, 499
Gunnera manicata, 37, 293, 806

Helicrysum bellidioides, 421; bracteatum, 319
Helleborus corsicus, 336
Hemerocallis, 703

Viola Maggie Mott, 199; Mrs. Marrison, 200; Sir R. Baden-Powell, 199
Vines, 719; culture of, 251
Voles, 729
Wahenbergia pumilio, 526
Wallflowers 648, 649; wall, dry 847
Willow, 296: weeping, 295, 296
Wistaria, multijuga alba, 843
Yew hedge, 349, 673

INDEX TO LETTERPRESS

Abies Fargesii, 167
Acacia monilliformis, 637
Æginetia indica, 250
Agathæa cœlestis, 48
Aldenham, the gardens at, 320
Allium, the genus, 4, 37, 72
Aloe, a flowering, 811
Alonsoa Warscewiczii, 654
Alpine house, 1; colour schemes for the, 26
Alpine lawn, the, 244
Alpines, late-flowering, 604; notes on native, 288; on the Monte Moro Pass, 351, 385; from the pass of Mont Cenis, 131; New Zealand, 575; the fifty best, 24, 73
Amaryllis Belladonna, abortive buds of, 132
American notes, 390
Anchusa italica Lissadell, 703
Androsaces, about, 8; imbricata, 38; primuloides, 50
Andromeda polifolia, 208
Anemones, 188
Anemone Seemannii, 288
Annuals, preparing ground for, 812; raising greenhouse, 25, 588; some desirable, 58; English, in Kenya Colony, 654
Antirrhinums, 52, 659, 786; culture of, 279; for spring flowering, 522
Aphides of the fruit trees, 326, 416
Aphyllanthes monspeliensis, 607
Apple, tree, an ancient, 741; varieties, 703; pruning, 23
Apples, 741; bud sports of, 250; dual-purpose, 14; late keeping culinary, 232; some old but first-rate dessert, 14
Arenaria montana grandiflora, 90
Argemones, 820
Aristolochia elegans, 803
Arundinaria Muriciæ, 56
Asters, 675, 701, 825; annual, 232
Aubergines, 623
Aubrietias on a wall, 326
Autumn colour in the garden, 816
Autumn notes from the West, 795
Autumn Show, 680
Avenues, the use of, 500
Azaleas, 624

Basket plants for greenhouse and conservatory, 224
Banks, treatment of and planting dry, 18, 39
Beans, broad, sowing of, 785
Bedding out, 398
Beeches, the Southern, 831, 845
Begonia, culture of the, 3, 20, 31, 44
Begonias, drying off, 609, 788
Berberis, deciduous, 644; berries, 52
Biennials, raising of, 433
Blossom, Christmas, 23
Bog garden in a basin, 473
Bone fertilisers, 796
Border, herbaceous, 163, 248, 290 summer, 575 the mixed, 608
Bowls, attractive flower, 181
Box at Bridge End Gardens, 388
British Carnation Society, annual show of the, 247
Brockhurst, the rock garden at, 82
Brodiæa ixioides, 736
Budding, the art of, 143
Buddleia asiatica, 173; Colvilei, 192; Farreri, 250
Bulb, moss fibre for growing, 289; planting in woodlands, 573; planting, the utilisation of, 568; early, 505; in pots, 567, 719; some early-flowering, 6, 257; South African, 732; the cultivation of flowering, 561; the lifting and storing of, 453; the potting of, 670; to buy, 563
Buttonbush, the, 821

Cabbage for spring, 555
Cacti, 179; from seed, 251
Calceolaria, the herbaceous, 361
Calliearpa Giraldiana, 184
Calystegia sylvestris, 607
Campanulas, border, 515; for the rock garden, 315; cæspitosa, 688, 752; linifolia at Mont Cenis?, 154
Canary Islands, vegetation, 859
Canterbury bells, culture of, 93; potting, 490
Cape pelargoniums, 546
Carnations, 702; propagation of winter-flowering, 812
Carnations, border, 219; for autumn planting, 745, 798, 758; winter and spring, 670; layering of, 522; border, in pots, 307
Caryopteris tangutica, 183
Catalogue, another, 430, 454
Cattleya Mossiæ var. Mrs. J. T. Butterworth, 488
Ceanothuses, 543
Celery blanching, 609; early, 76; fly 522
Celsia cretica, 309
Cephalaria tartarica, 814
Chalk garden, notes from a, 467
Changes in plant names, 652
Chelsea Physic Garden, 516
Chelsea Show, 375
Chinquapin, 821
Choisya ternata, propagation by cuttings, 309, 344, 361, 411, 454, 473, 489
Chrysanthemums, 457, 629; early flowering, 61, 297; feeding, 573; health among, 720; Japanese, 254; new, 717; potting and stopping, 172; potting rooted cuttings of, 85; "taking" buds, 539
Cinerarias, the cultivation of, 834
Clematis macropetala, 224; erecta, 623; the large-flowered hybrid, 693
Clianthus puniceus in south-west Scotland, 342
Climbers, for the greenhouse, 275, 768; hardy, 433
Climbing plants, outdoor, 722; summer treatment, 505
Colour combinations, 811
Columbine, a good woodland, 473
Coniferæ, a handbook of, 22
Continental botanic garden, 772
Convolvulus, perennial, 195, 283, 291
Cornflower, a good perennial, 342
Cornus officinalis, 333
Cornwall, 823
Corylopsis Gotoana, 419
Creeping plants, a few rare, 431
Crocus, Dutch, 309; the saffron, 538; hyemalis, 591; Imperati, 131; autumn-flowering, 842, 843
Cucumber culture, 418
Cucurbita ficifolia, 735
Currants, black, and big bud, 170
Cyclamens, greenhouse, 101, 689
Cymbidiums, 161
Cypella Herberti, 173
Cypripediums, the, 812
Cytisus scoparius pallidus, 419; monspeculanus, the hardiness of, 25

Daffodil Show, the Midland, 322, 363
Daffodil Everest, 287; King Alfred, 132, 213, 249; Nevis, 287; Sentinel and Mitylene, 411, 439; Tenedos, 287; in the U.S.A., 849
Dahlias, popular, 238, 259
Daphne Laureola, 212, 248, 290, 327, 411
Delphiniums, 214, 643, 752; cultivation of, 146; the Wrexham, 797; as a name, 113, 194; nudicaule, 861
Delnanthe cœrulea, 132
Dendromecon rigidum, 23
Deutzia longifolia, 582
Diascia barberæ, 572
Digging, 780
Dipelta floribunda, 583
Dropmore, the conifers at, 264; the gardens at, in early summer, 195

Edinburgh, Royal Botanic Garden, 600
Emmenopterys Henryi, 81
Enkianthus, 429
Erigeron, a rare trailing, 342
Erinacea pungens, 456
Eucryphia, a hybrid, 270; pinnatifolia, 9, 37, 91
Eupatoriums, 342; Weinmannianum, 823
Everlasting flowers and their culture, 319

Ferns, hardy British, 532; potting young, 704
Floraire, notes from, 17, 205
Flower lawns, 538
Flowers, American wild, cultivated in England, 310; autumn, 736; blue, 483; early hardy, in a suburban garden, 69; June, 521; the marketing of, 304, 511
Fothergillas, 55
Frames in summer, 474; in winter, 624
France, notes from, 310
Freesias from seed, 604; some Whitewell, 288; the cultivation of, 570; seedlings outside, 9, 37
Fremontia californica, 72
Friends and foes of the garden, 728, 760, 774, 810, 850
Fritillaria Imperialis, 343; pyrenaica, 271
Fruit-growing in small gardens, 213; protecting autumn, 62
Fruit, protecting blossom against frost and birds, 300; bottling at home, 551; cultivation in Scotland, 358; gathering and storing, 655, 748; growing in small gardens, 99, 121, 145, 162, 193; varieties suitable for Yorkshire, 813
Fruit trees for small gardens, 814; grease-banding, 650, 670; in pots, 638; planting of, 753; pruning neglected, 88; summer pruning, 490
Fuchsias, 727, 765

Garden, alpine lawn, 308; design, 801; a small, 858; folk-lore, 662; furniture, 484; soils, 718; a tropical, 537; fragrance in the, 520; plants in an old cottage, 679
Gardens at Wembley, 186, 700, 721; old and new, 214; of India, 104, 285, 374; the charm of, 819; small, of London, 299; cottage and railway-station, 497, 551; hardy perennials for sub-tropical, 836; knot, 616, 688, 719; small, 553
Gardening, fashions in, 818; in the Middle Ages, 810; law, 581
Genista tinctoria, 552
Gentiana acaulis, 307; gentilis, 804; verna, 344, 363, 389, 454
Geranium anemonæfolium, 437; Farreri, 455; atlanticum, 174
Gladioli, 361; cultivation of the, 59; comments on, 335; how I came to grow, 139
Gladiolus byzantinus, 520
Gloxinia, cultivation of the, 59
Gooseberry mildew, 280, 554; saw-fly, 575
Gothenburg Botanic Gardens, 772
Gourds, ornamental, 103
Grafting, 184
Grapes, growing of, 251; how to keep ripe, in winter, 785; thinning of, 474
Gravetye Manor, notes from, 336
Greenhouses, construction and heating of, 133; heating apparatus, 697; a novel method of heating, 824
Grouping and colour, notes on, 341

Hardy perennials for sub-tropical gardens, 792
Heaths, summer-flowering hardy, 448
Hedges, 349, 768; cutting, 539
Helichrysum bellidioides, 423; frigidum, 9
Hellebores, 132
Hemerocallis, 703
Herbaceous borders, clearing of, 655; planning a straight, 794
Herbs, 624
Hibiscus Waimea, 767
Holly blossom, 424
Hollies, 850; flowering, 575
Hollyhocks, 786
Hyacinths, prepared Cynthella, 21; prepared, 131
Hybridisation, indiscriminate, 454
Hydrangea, a new, 821; colours in, 837

Impatiens Roylei alba, 702
Imperial Botanical Conference, 252
Insecticides, 534
Insect pests, 490
Inventory of a garden, 779

THE GARDEN

No. 2720.—Vol. LXXXVIII.] [January 5, 1924.

THE ALPINE-HOUSE

IT is at this season of the year that one appreciates most the dainty treasures of the alpine-house, and many amateurs who possess a cold greenhouse will determine, after seeing a particularly good display in some other garden, to utilise their own structure for the same purpose. The only doubt in the mind of many with a cold greenhouse at disposal is its suitability for the purpose. Since most of the plants which one would wish to grow, flower in the dark days—or at any rate make growth then—it is necessary that the house should get as much light as possible, but given an open position almost any type of structure may be pressed into service. Very low span-roofed pits, such as are used (when heated) as Cucumber-houses, are much favoured for the culture of rock plants under glass, but they are by no means essential, for a palm-house no longer required for the purpose for which it was built, may, to go to the other extreme, be made to answer admirably.

The question is often raised as to whether culture in pans or on a rockery is most satisfactory. From a cultural standpoint there is little to choose, so that it largely resolves itself into a matter for each one's taste to decide. Culture in pans has this advantage, however: the plants may be plunged in frames outside for the summer months, leaving the house free for other purposes, whereas those planted out will need a fair amount of attention if they are to remain healthy and give of their best another season. Many gardeners prefer the rockery as giving a more natural setting, but one needs a helpful imagination to make rockwork seem natural in a greenhouse.

We will suppose that it has been decided to build an alpine-house or to utilise an existing structure. The next point for consideration is the plants with which to stock it, and since the owner will have to "live with it," he will be wise to see as many alpine-houses as possible when the plants are in bloom and to take note of attractive kinds. The list which follows will, however, supply plants which satisfy the tastes of most people.

The alpine-house is especially suitable for the culture of choice and tiny species which, though perfectly winter-hard, are apt to be lost through fog and damp or from other causes—*e.g.*, slugs or woodlice—if planted in the rock garden. In this class we have Campanula Allionii and C. Zoysii, and if trouble is found in growing them outdoors, CC. pulla, Waldsteiniana and garganica; all these are lime-lovers.

Among Saxifrages we have such tiny jewels as SS. lilacina and retusa, the slug-beloved S. tenella which belongs to the Trachyphyllum section and almost all the Englerias which it is thought worth while to grow, such as SS. thessalica, media, Grisebachii and Frederici-Augusti. That rarest of Encrusteds, the cliff-loving S. florulenta, if seed or seedlings can be obtained, is also worth a place, and the same may be said of S. mutata, with yellowish spires and curious membraneous rosettes of darkest green.

It is when we come to the twin genera of Primula and Androsace that we really get a plethora of choice species which are best in the alpine-house. Among Primulas, the beautiful P. Winteri comes first to mind, and no alpine-house can be considered decently furnished which does not include it; then we have the not over-hardy P. Forrestii, which likes to work its roots far into the interstices of a "cliff." Primulas of the nivalis group—not too easy anywhere—should, if attempted, have the shelter of the alpine-house, and the same applies to the curious Omphalogramma species, such as vincæflora and Violagrandis. The easiest of the nivalis section, or at any rate the easiest of those in commerce, is P. chionantha with creamy white blossoms reminiscent of those of P. sikkimensis, but most of them should present no insuperable difficulty under glass. The Primulas of the Auricula clan are, generally speaking, perfectly easy outdoors, but the golden farina of P. marginata, for instance, shews to great advantage when protected from the weather.

Where the atmosphere is pure, there is no obstacle to the successful cultivation of such Androsaces as sarmentosa, primuloides, × Chumbyi, villosa, carnea, Laggeri and lactea outdoors; where the garden lies anywhere near a manufacturing town, however, they will be safer under glass. For the Aretia section the alpine-house is practically essential. A. helvetica is probably the most grown of this section, but A. Charpentieri presents no difficulty and is very delightful.

The Onosmas, again, though generally speaking easily cultivated outdoors, shew to much better advantage under glass, and the silvery-downed foliage of O. albo-roseum, in particular, is really beautiful. Even the Golden Drop, Onosma tauricum, is not really

THE ROSY PRIMULA VEITCHII IS NONE TOO HARDY.

Digitized by Google

satisfactory outdoors where the air is at all impure, though it will succeed under glass in a suburban garden. Closely akin to the Onosmas are the Lithospermums, and of these L. rosmarinifolium is not quite hardy outdoors in most parts of the country; moreover, it flowers in the dead of winter, and so can only shew its beauty satisfactorily under glass. The species of Myosotis which hail from the Antipodes are best in the alpine-house, and these include the sulphur yellow albo-sericea with silvery, silky foliage and Cheesemannii and decora with white flowers. The alpine M. rupicola, too, is well worthy of cultivation under glass. The alpine-lover who must attempt Eritrichium nanum should give it a place in the alpine-house, and when he has flowered it there, which with ordinary care he should, he will probably bother no more with it.

Cruciferous plants are, generally speaking, of the easiest culture, but Æthionema coridifolia (Iberis jucunda) and Draba (Petrocallis) pyrenaica represent exceptions to the general rule, though they are amenable enough under glass.

The Composites, too, are, almost without exception, easy doers, but most, if not all, the Celmisias are either tender or on the very border-line of hardiness. Some stock of all those procurable should be kept in the alpine-house.

Of the alpine Helichrysums the same might almost be written, though the gay and beautiful H. bellidioides is hardy (and certainly easy) in most gardens. H. frigidum (a Corsican) is an especial treasure for the alpine-house and not easy even there, while there are a number of other beautiful species which would repay culture.

Of the Wood Sorrels, Oxalis enneaphylla and O. adenophylla are perfectly hardy, but the autumn-blooming golden O. lobata and the free-flowering O. rosea are more uncertain, though the latter often naturalises itself from self-sown seed.

Very few of the choicer kinds of Pentstemon are reliably hardy, though a few cuttings under glass should suffice to retain stock in case of a hard winter. The following are some of the best for the alpine-house: PP. angustifolius, Newberryi (by no means to be confused with P. Newbury Gem), Davidsoni and Scouleri.

The Potentils, again, are in a general way easy and hardy, but numbers of good gardeners find the beautiful Potentilla nitida rather difficult outdoors, and, where the atmosphere is at all sooty, the alpine-house is the place for it.

Mesembryanthemums—even the hardiest of the race—will stand outdoors in this country only in favoured localities, but the hardier species are useful in the alpine-house in company with the Lewisias, hardier Cotyledons and Sedum dasyphyllum.

The foregoing have been selected because difficult to "do" outdoors. Space found for such of them as we may fancy, our attention can be turned to the multitude of suitable plants which may also be grown outdoors. There are, of course, numbers of plants not included above which are not reliably hardy in bleak situations, such, for example, as Primula Veitchii and the forms (some very beautiful) of P. Sieboldii, but the genus Primula, to take one great race of plants, provides a number of species worthy of any greenhouse. What could be more beautiful than the splendid pink forms of P. pulverulenta, for instance, or more brilliant than the short-lived P. Cockburniana. Then we have the hundred and one mongrel forms now placed under P. × pubescens. The beautiful white form belongs here which, in gardens, is often grown as P. nivalis, and this is especially charming under glass. The writer once raised a small batch of seedlings of this, every one of which proved white, but cases have been recorded where the seedlings all approximated to a rather dingy P. hirsuta.

VERY BEAUTIFUL FOR THE ALPINE HOUSE, SAXIFRAGA MARGINATA.

BEAUTIFUL IN FLOWER AND FOLIAGE, SAXIFRAGA LINGULATA VERA.

ANOTHER JEWEL FOR CLOSE INSPECTION, SHORTIA UNIFLORA.

THE CULTURE OF THE BEGONIA.—I

THE Begonia, considered in its widest sense, so that the fibrous as well as the tuberous rooted forms are included, is one of the most important as well as the most beautiful of greenhouse and garden flowers. So diverse are its forms that, if one were so minded, a really large greenhouse might be filled with Begonias alone, without the slightest risk of monotony. Another strong point in their favour is that there is no gap in their flower display from January 1 to December 31, without taking into consideration the splendid foliage effect of such forms as BB. Rex, Haageana, metallica and a host of others.

One of the chief interests at the present date will be seed sowing, for it is by this means that immense numbers of plants of average quality are raised for bedding purposes, etc., in the open air, while, at the same time, the finest and best forms are picked out for culture in pots in the greenhouse or conservatory. Such gardeners as maintain a high standard of quality among Begonias (more especially among the doubles) will find this work of selection most fascinating, and much depends upon the quality of the strain as to how high a percentage of prizes are discovered when flowering time comes. Much of the fascination comes from the result of one's own fertilising and cross-fertilising, but if one does not collect one's own seed, one should not fail to procure it from a reliable source.

Considerable care is required, both in sowing and in the management of the young seedlings. Early sowing is essential, in order to procure plants that will flower the same summer. The compost used should consist mainly of good loam with a small admixture of leaf-mould, broken charcoal and coarse sand. Shallow seed-pans are best, and these should be efficiently drained by placing one large crock over the drainage hole and a number of smaller ones on top of this. Owing to the minute size of the seed, a very fine surface is necessary, and this can only be ensured by sifting sufficient compost to provide a top layer about an inch thick. Below this, the soil should be used in a coarser condition, in order to prevent the drainage becoming blocked. It is almost impossible to cover the seed sufficiently lightly with soil, and the best way is simply to scatter the seed on the surface and ensure the requisite darkness by covering each pan with a sheet of brown paper and a pane of glass on the top. Place the pans in a steady temperature of 65° to 70° Fahr., reverse the glass daily to disperse condensation, and watch for the first signs of germination.

The surest and safest method of applying moisture, when required, is to immerse the pan to half its depth in tepid water and allow it to remain until, by capillary attraction, the whole of the soil is thoroughly moistened. It is, naturally, very important that the soil be never allowed to approach dryness. The life germ is so minute that a very brief period of drought is sufficient to destroy it—a point that should not be overlooked at a later date also, when the spring sun begins to gain in power. Keep the paper covering on until tiny white thread-like roots are seen emerging from the base and little green tips begin to appear on the surface; then remove the paper and cover only with the glass. As the plants progress, this also should be gradually dispensed with. First tilt it up slightly by inserting a match, then increase this by the use of a label, and finally withdraw the glass by degrees until the plants become accustomed to the air of the house in which they are growing. Unless the seedlings are crowded, it is better to defer pricking off until the plantlets have attained some size and vigour; but it is better to do this earlier by means of a match, upon the point of which they can be picked out, than allow them to jostle each other.

It is wiser at first to prick off into further pans or boxes than into single pots. Give them 1½ins. from plant to plant, as this enables them to grow for some time without further disturbance. Leaves about the size of a halfpenny should be formed before they are transferred to single pots, and in all cases additional care must be exercised both in watering and shading for a short time after transplanting. See that the soil is pressed quite firmly round the roots, water well, and place again in a similar temperature. While they must on no account become dry, less water at the roots will be requisite until they begin growing again; but do not fail to keep the atmosphere humid. Though progress is very slow during the earlier stages, an astonishing increase of growth will be noticed when they have once attained some size, and it is then that the first potting should be done. The original compost should be modified by the addition of some well rotted cow manure and by the almost entire elimination of sand, which is very liable to encourage the begonia mite. One has only to keep the atmosphere thoroughly humid and the temperature level to be rewarded by astonishingly vigorous and rapid growth.

If the ultimate destiny of these plants is outdoor work (and few better ways can be found for testing their qualities), it will not be necessary to repot into larger pots. Grow them on as rapidly as possible, and so obtain as large examples as you can by early June; but if a proportion is intended for greenhouse flowering, continue to repot into larger sizes as fast as their roots fill the smaller ones. Do not omit very careful hardening off of all outdoor plants, first by transferring the plants from the house in which they were sown to a cooler one with more air, then to a cold frame during their last week, in which full exposure to air should be given. Never plant out until June is well in and the weather has really settled, and see that plenty of water is provided. It is well to remember that the most backward plants are usually of the finest quality, and, when making a selection between plants to be grown under glass and plants for bedding purposes, it is the smallest and weakest looking that should be reserved for pots.

Outdoor plants need a rich, deep, moist soil to do their best, and, contrary to the generally accepted idea, will render an excellent account of themselves, even in full sun. Here they should

WELL-FLOWERED PLANTS OF DOUBLE BEGONIAS. *Copyright, Sutton and Sons*

Digitized by Google

remain until after the first frosts have blackened the tops, when they should be lifted without delay and spread in a cool dry place until the stems part easily from the tubers, when the loose earth should be shaken from them and the tubers be stored in sand or peat-dust until the following spring.

H. W. CANNING-WRIGHT.

(To be continued.)

THE GENUS ALLIUM

Despite their disagreeable odour when bruised or handled, many Alliums are worth growing. They are of easy culture and very free-flowering.

THE genus Allium belongs to the natural order Liliaceæ and consists of nearly 300 species, distributed over the temperate regions of the Northern Hemisphere. They are mostly bulbous plants, many, like the common Onion, strongly scented, this characteristic being the chief reason why the members of this genus are not very popular in gardens. There are, however, many very pretty and ornamental species, well worth growing, and suitable for various situations and conditions. Some, like AA. ursinum and triquetrum, are valuable for naturalising in the open woodland, while others, like AA. cyaneum and kansuense, are charming little plants for the rock garden.

From an economic point of view the genus is important, as, from different members, several valuable vegetables are derived, including the Onion from A. Cepa, the Leek from A. Porrum, Chives from A. Schœnoprasum, and the Shallot from A. ascalonicum. This genus is also remarkable in that the three primary colours are represented in the flowers, those of AA. cyaneum and cœruleum being blue; AA. flavum and Moly yellow; and AA. Ostrowskianum and narcissiflorum having red flowers; while the white section is represented by A. neapolitanum. Besides, there are many kinds with flowers of all intermediate shades of colour. All the species are hardy in this country and are easy of culture, increasing rapidly by means of offsets. These little bulbs, which in the case of many species are produced in clusters, may be separated and replanted in autumn or early spring about 3ins. deep. Seeds also are freely produced. These may be sown thinly in light soil in February and March in the open border, where they should remain until the autumn or following spring, when they may be transplanted to their permanent positions. Seeds may also be sown in boxes or pans in a little heat in February, and the young plants be transferred, when large enough to handle, to the sites where they are to flower. The following are some of the best kinds:—

BROAD-LEAVED GARLIC, ALLIUM URSINUM.

THE ROSY-FLOWERED ALLIUM KARATAVIENSE.

A. ALBO-PILOSUM.—This handsome kind has probably the largest flowers in the genus. It was collected by Sintenis in the year 1901, in the mountain ranges which divide Transcaspia from Persia. It has large bulbs with strap-shaped leaves, 18ins. long, and nearly 2ins. broad, glabrous above, with longitudinal lines of white hairs beneath and on the edges. The stout scape rises to a height of nearly 2ft. and bears large heads 9ins. across, composed of from sixty to eighty flowers. These are each 2ins. in diameter, and in colour a deep lilac with a metallic sheen. It comes into flower in June, and lasts for a considerable period in full beauty.

A. ACUMINATUM.—From North-western America, this species grows to a height of 9ins., with deep rose-coloured flowers nearly 1in. across, borne in many-flowered umbels, during July and August. The leaves are narrow, and die off early. There is a more deeply coloured variety with red-purple flowers.

A. AMBLYOPHYLLUM is a distinct species, of dwarf habit, with small bulbs, flat leaves and umbels of lilac flowers, which are produced in July. It hails from Turkestan.

A. AZUREUM.—This is a handsome tall-growing kind from Siberia, with triangular leaves 6ins. to 12ins. long, and scapes 18ins. high, bearing dense globular heads of deep sky-blue flowers in summer

A. BIDWELLIÆ is one of the dwarfer kinds, suitable for the rock garden, growing only a few inches high, with few flowered umbels of bright rose-coloured blossoms which are produced in July. This plant comes from Sierra Nevada.

A. CŒRULEUM is closely allied to A. azureum, but is not so tall, only reaching a height of 8ins. It produces globular heads of blue flowers in June, and is a native of Russia.

A. CYANEUM.—There are three charming little blue-flowered species of dwarf habit, very much alike in appearance and all suitable for the rock garden. Unlike many of the others they are perennial and flower year after year without attention, except keeping them clear of weeds. They are AA. kansuense, sikkimense and cyaneum. The latter species has narrow grassy leaves, channelled above, with slender stems about 8ins. high, bearing nodding umbels of blue flowers in summer. It is a native of Kansu in China and was introduced into cultivation in 1840.

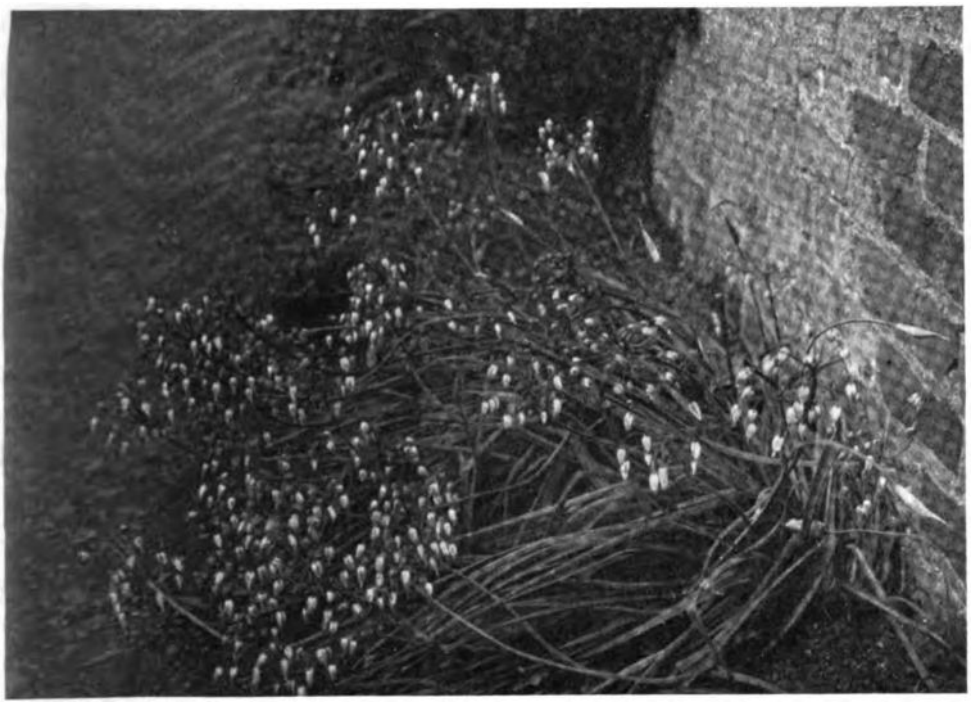
A. ERDELII is a rare, but pretty little species hailing from Palestine and only grows about 6ins.

Digitized by Google

high. The flowers are white and borne in compact umbels. This plant requires a warm position against a south wall, or a sheltered position in the rock garden.

A. FETISOWI grows about 2ft. high and produces flat leaves and many-flowered, hemispherical umbels of rosy-lilac flowers. It is a native of Turkestan.

A. FLAVUM is a slender-growing species, about 1ft. high, with round, but not hollow leaves, flattish above the base. The yellow, bell-shaped and somewhat drooping flowers are borne in umbels during the summer. This is a very old garden plant, having been introduced from Italy, its native habitat, some 150 years ago.



THE MAUVE PURPLE ALLIUM MACRANTHUM.

The three illustrations shew plainly the immense variations in flower and foliage of which the genus is capable.

A. GIGANTEUM.—This plant is one of the tallest members of the genus, growing up to 4ft. high. It has large bulbs, fleshy leaves, 18ins. long and 2ins. wide in the middle. The bright lilac flowers are borne in dense globose umbels 4ins. in diameter. It is a plant for the fern border or wild garden and comes from Central Asia.

A. KANSUENSE is very closely allied to A. cyaneum, but has shorter stamens. This is a pretty little species for the rock garden. It grows about 6ins. high and produces numerous grassy leaves and leafy stems, bearing umbels of dark blue flowers during the summer. As its name implies, it is a native of Kansu in China.

A. KARATAVIENSE (syn. A. Akaka).—This is a very distinct Allium with very broad, flat leaves, ovate-oblong in shape and very glaucous. The scapes are about 6ins. or more high and bear dense, convex umbels of pink to rose-coloured flowers in May. It is a good plant for the herbaceous border and is a native of Turkestan.

A. MACRANTHUM.—This handsome plant comes from the Eastern Himalayas, and is a good perennial, the rootstock being composed of a dense tuft of fleshy root fibres. The leaves are flat, over 1ft. long, from among which the scapes are produced freely to a height of 2ft. These bear loose umbels of fifty or more bright, mauve-purple flowers in July. This species does best in a warm position at the foot of a south wall, but it will also succeed in the rock garden if given a sunny aspect. It is readily increased by means of division when the roots are at rest in the autumn or spring.

A. MOLY.—This is a very old garden favourite, having been in cultivation since the year 1604. It is a bulbous species, with broad glaucous leaves, and scapes 10ins. to 15ins. high, bearing compact umbels of bright yellow flowers in spring. It is very effective in masses and is a valuable plant for naturalising in a warm sunny position. It comes from South Europe.

A. NARCISSIFLORUM.—This is the narcissus-flowered Allium from Italy. It is an elegant plant, with nodding umbels of beautiful rose-coloured flowers, which are produced in July. It grows about 9ins. high, and is worth a place in the rock garden. It should be given a sunny position.

A. NEAPOLITANUM (syn. A. lacteum).—This well known South European species may be naturalised in the wild garden or fern border, where it makes an effective display during the early summer. It may also be employed as a pot plant, and is useful for forcing. The bulbs should be potted up in autumn, using a sandy soil. They should then be plunged in a bed of ashes, and when well rooted and starting to grow, transferred to a cold frame till they are ready for the greenhouse. It grows up to 18ins. high, has flat leaves, and is the most ornamental white-flowered species.

A. NIGRUM (syn. A. magicum).—This is a tall-growing plant, up to 3ft. high, with umbels of dull violet or whitish flowers, which are produced in summer. It is a native of South Europe and is an excellent plant for the wild garden.

A. OREOPHILUM is one of the smaller, more select kinds. It is only 4ins. high, with narrow leaves and umbels of reddish-purple flowers, which are borne in July. It is a native of the Caucasus and Siberia.

A. OVIFLORUM.—This is closely allied to A. macranthum, and has deep violet-purple flowers, ovate in shape, produced in lax umbels. It comes from the Chumbi Valley in the Himalayas.

A. OSTROWSKIANUM.—This plant is closely allied to A. oreophilum. It has rose-coloured blossoms, which are disposed in many-flowered umbels on scapes 6ins. high. The flowers open in July. Both are worth a place in the rock garden or select border, are easily grown and flower freely. A. Ostrowskianum is a native of Turkestan.

A. PEDEMONTANUM is a neat little plant, suitable for the rock garden. It comes from the Piedmont and has large, bell-shaped, rosy-purple flowers which are borne in graceful drooping clusters during July. It thrives best in a warm situation.

A. PULCHELLUM.—This is a good border plant and is very effective in masses. It grows about 2ft. high, with narrow leaves and violet-coloured flowers borne in umbels. It is a native of the Orient and flowers during the summer months.

A. ROSEUM grows about 1ft. high, with strap-shaped leaves rolled inwards at the top, and bears umbels of pale lilac-rose flowers. It comes from South Europe.

A. SCHUBERTI is probably the most remarkable plant in the whole genus. It has large bulbs, broad flat leaves, more or less undulated, and stout scapes over 1ft. high. These bear umbels of from 50 to 200 flowers, the pedicels of which vary from 2ins. to 6ins. in length. The whole makes a sub-globose umbel sometimes 1ft. in diameter. The flowers are rosy-red in colour and last throughout the summer months. It is a biennial and dies after flowering. However, seeds are produced freely, so plants may be readily raised. It is a native of the Orient and has been in cultivation about twenty years. This is a good plant for a sunny border.

A. SIKKIMENSE.—This is a compact, neat little plant, some 6ins. high, with grassy leaves and deep blue flowers borne in loose umbels. It flowers from June to August and prefers a half shady position in the rock garden, where it has proved itself a good perennial. It hails from Sikkim.

A. SUBHIRSUTUM (syn. A. ciliatum).—This is another white-flowered species in the way of A. neapolitanum, but having hairy leaves. The umbels are fewer flowered, white, or with the middle nerve more or less purplish. It also comes from South Europe.

A. SICULUM (syn. Nectaroscordum siculum).—This plant is a remarkable biennial, with broad flat leaves and scapes 3ft. or more high. These bear umbels of drooping, dull, purplish-coloured flowers in summer. It is characterised by a very strong odour when bruised. A native of Sicily it comes up freely from self-sown seedlings.

A. TRIQUETRUM is a pretty little native plant well worth naturalising in the fern border. It grows 12ins. to 18ins. high and has green leaves, which are keeled in a triangular manner. The white bell shaped flowers, with a narrow streak of green down each segment, are borne in loose, drooping umbels on triangular stems during the summer months.

A. URSINUM (broad-leaved Garlic; Ramsons).—This is another native species that is often met with in large masses in open woods. When in flower it is very effective, clothing the ground with its broad green leaves, above which the numerous umbels of white flowers are borne on scapes 1ft. high.

A. VICTORIALIS is one of the most distinct species, with stems 1½ft. to 2ft. high, clothed with lily-of-the-valley-like leaves. The white, or greenish-white flowers are produced in umbels in May. It is a native of Southern and Eastern Europe, and is somewhat rare in gardens. W. I.

FORTHCOMING EVENT.

SOME EARLY-FLOWERING BULBS

BY W. R. DYKES, M.A., L.-ès-L.

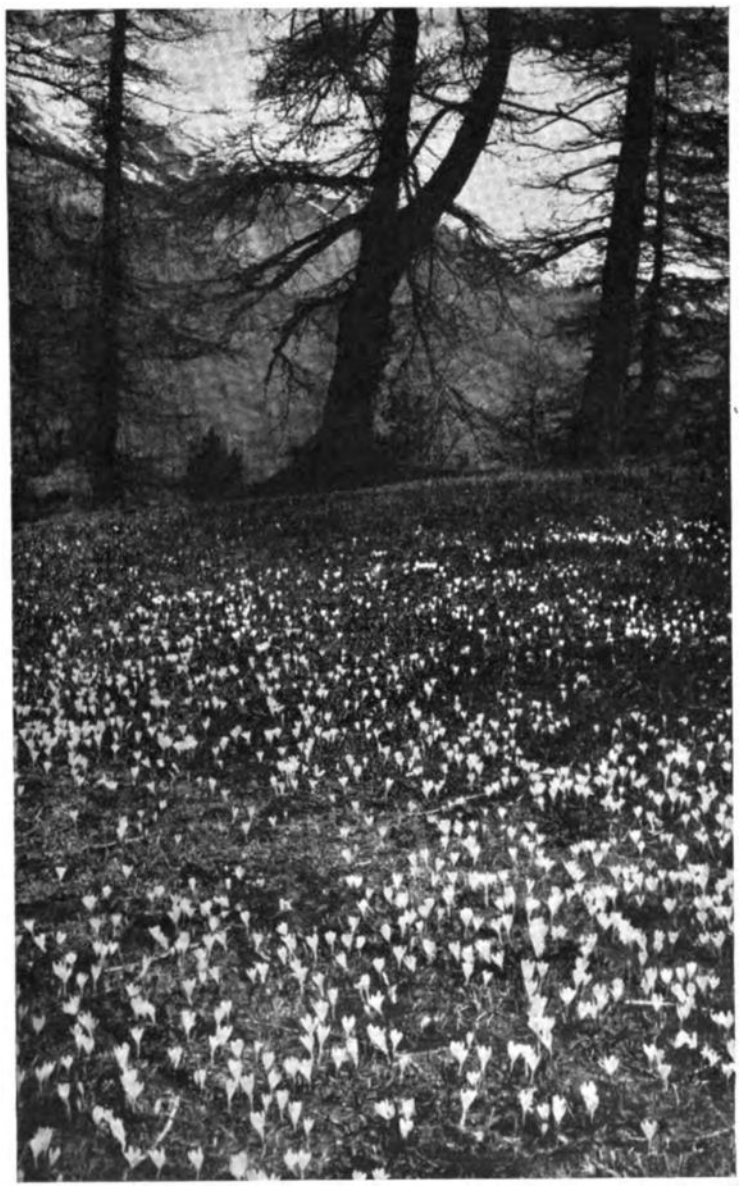
FOR many gardeners there is a fascination about bulbs which is not possessed by any other class of plants. In the early months of the year some of this fascination is, no doubt, due to the way in which the bulb prepares its flower underground, quite regardless of the weather conditions, and is ready to produce it during any spell in which the surface is not frozen hard. Then, when the bulbs are lifted later on, there is the fascination of the new clean bulb which emerges from its wrappings of the old skins of the previous year or years and which even then contains within it the bud which will develop into the flower of the next season.

The bulbous species, which are in cultivation at all, tend to be rare or common according as they increase slowly or rapidly by means of offsets: for the raising of bulbs from seed is, in most cases a very slow process. For instance, Tulipa Greigi, one of the most shapely and beautiful of all Tulips, very rarely produces a single offset; in fact, although for at least fifteen years I have cultivated a number of bulbs of this species, it was not until 1922 that I obtained my first offset. Seeds of this Tulip are not easy to obtain, and it takes seven years to produce flowering bulbs from seed. This fact and the impossibility of collecting further supplies of bulbs while the home of the species in Turkestan is in the hands of the Bolshevists, account for the rarity of T. Greigi. There is, undoubtedly, an opening for anyone who will set to work to raise the rarer bulbs from seeds in large quantities in this country. It can be done, but it will need patience at the outset.

One of the earliest Tulips to flower, and one that has the additional merit of increasing by offsets, is T. Kaufmanniana, a species which apparently grows alongside of, if not actually with, T. Greigi in their native home in Turkestan. T. Kaufmanniana is especially valuable because it comes into flower at the end of February, and a bed of it in full flower makes a glorious sight on some sunny day in March. The green buds of Darwin Tulips are a familiar sight, for we watch them on the lengthening stems for some time before any colour is apparent. T. Kaufmanniana, on the other hand, contrives to develop the full colour of its flowers while they are still within the wrapping leaves and practically beneath the surface of the ground. Consequently, it only needs one or two sunny days to produce a blaze of colour, where previously there was little to be seen but the closely wrapped, shooting leaves.

The usual type of this Tulip has white flowers with a yellow centre, and the backs of the three outer petals are more or less vividly streaked with red or even with a faint purplish blue. Other forms have wholly yellow flowers, with scarlet on the backs of the outer petals; while others, again, are wholly red.

Among other early-flowering Tulips are two interesting species, T. biflora, from South-Eastern Russia, and T. turkestanica. Both have small, starry white flowers with a yellow centre and a branching stem, which in the former may bear three or four or even six flowers and in the latter as many as ten or twelve. The chief difference is that in T. biflora the yellow extends from the centre of the flowers almost halfway up the petals, while in T. turkestanica it is confined to the centre of the flower. T. turkestanica is further distinguished by its chocolate pollen, for that of T. biflora is yellow.



CROCUS VERNUS IN SWITZERLAND.

BULBOUS IRISES.

Some of the most beautiful and earliest to flower of all bulbous plants are the Irises of the reticulata section. The almond-scented grey-blue I. Vartani from Palestine may be in flower at Christmas, and there is a white form of it spotted with blue which is extremely beautiful. It is closely followed by I. histrioides, from the mountains of Northern Asia Minor, with its large flowers of a brilliant blue which appear before the leaves have had time to develop. This late growth of the foliage is an advantage to the plant, because it has a better chance of attaining its full development later than has, for instance, I. Vartani, of which the leaves are often so severely damaged by bad weather that no sound bulbs are formed for the succeeding year.

The same fate often overtakes I. Histrio, which in some of its forms differs chiefly from I. histrioides in the earlier development of its foliage, and the yellow I. Danfordiæ, from mountains of Cilicia, which is distinguished by the fact that its standards are reduced to mere bristles, so small as almost to escape notice altogether. Even more brilliant than any of these is the rare I. Bakeriana, with its falls tipped with blue-black velvet and its slender eight-ribbed leaves. All these Irises need a sheltered sunny corner in rather rich light soil made porous by the addition of a liberal supply of lime rubble. Several of them form, at the base of the flowering bulb, a number of minute bulblets, which, if left untended, rarely develop into full-grown bulbs and which need careful nursing for a year or two, either in pots or planted out in a cold frame. I. reticulata itself and its wild red-purple counterpart from the Caucasus, commonly known as Krelagei, come later in February and March and are better able to take care of themselves.

There is also a variety of garden origin with pale blue flowers which has been named Cantab, and which, like the deep blue typical form, seems to have something in its constitution which enables it to persist and increase in gardens and under conditions where the wild forms die out after a few years. There is a central line or ridge of deep yellow on the falls which is clearly seen in the illustration on page 8.

Of early-flowering Juno Irises the most wonderful is easily I. Rosenbachiana from Turkestan, with its brilliant flowers of all shades of colour from white to deep blue and red-purple, set off with a conspicuous golden crest. This and the many varieties of species akin to I. persica need sheltered positions and protection after flowering to enable them to mature their foliage; but the white and yellow I. bucharica, the golden I. orchioides and the purple I. warleyensis, which do not flower until April, should hold their own in well drained soil in any sunny spot that is not too wind-swept.

CROCUSES.

Crocuses are not, strictly speaking, bulbous plants at all, for their corms are solid throughout and do not consist of the eccentric wrapping skins which make up the true bulb. However, Crocuses should be found in every bulb garden

Digitized by Google

and not merely the common yellow Crocus and the well known purple and white varieties of C. vernus. Few are more beautiful in the early days of the New Year than the Italian C. Imperati from the neighbourhood of Naples. The outer petals are backed with a light buff colour, more or less distinctly veined with deep purple, and this colour contrasts strongly with the inner surface and with the inner petals of bright lavender. C. Imperati is a strong and vigorous grower and increases both by offsets and by seeds. There is also a creamy white albino form which comes true from seed. Each seedling corm of C. Imperati seems to have an individuality of its own. Some are precocious and flower early, and others are much more backward, with the result that three months sometimes elapse between the flowering of the earliest and the fading of the latest.

The Greek C. Sieberi is usually in flower in February and is of a particularly pleasing shade of blue with a golden yellow throat, which is displayed when the flowers open in the sun. With it comes the deep yellow C. Balansæ from Western Asia Minor, of which the outer petals are either veined with dark brown purple or even wholly backed with rich mahogany, so that the buds appear almost black. About the same time, too, comes C. chrysanthus, at once one of the most beautiful and most variable of all Crocuses. Its flowers may be of a deep golden yellow or lemon yellow or a soft butter yellow, as in the variety E. A. Bowles, or white more or less veined or flushed with purple on the backs of the outer petals. The beauty of the flowers is always enhanced by their rounded, goblet shape.

The Crocus vernus of the Swiss Alps, which appears in countless numbers in many places almost as soon as the melting snow recedes from the ground, is the parent of practically all the white and purple Crocuses that bulb catalogues advertise. In the hands of the florist and in the rich soil of the bulb gardens these Crocuses have grown fat and almost bloated, and have lost much of the grace and slender outline of the wild plants. Still, there are some, like the pure white Kathleen Parlow and the soft lavender Margot, which should have a place in every garden, though, for preference, it should be where the flower will not come into sharp contrast with the wild species.

THE CURIOUS, BUT BEAUTIFUL GALANTHUS SCHARLOCKI.

SNOWDROPS.

Snowdrops are universal favourites, but those who only know the common Galanthus nivalis would be astonished to see in flower in January the beautiful large-flowered form which used to grow so well at the foot of the famous wall in Canon Ellacombe's garden at Bitton, or the broadleaved G. plicatus and the giant flowers of some forms of G. Elwesii. The Bitton Snowdrop has long gone under the name of G. Imperati, but a reference to the original description of this species shewed that the true plant should be really a late-flowering form of G. nivalis. An importation of collected bulbs from the home of the species some ten miles east of Naples has given us some very pleasing forms, but throws no light on the origin of the plant which Canon Ellacombe grew. Most Snowdrops appreciate a rather cool soil rich in humus, though the Asia Minor species seem to need baking and a rest in summer. They should be disturbed as little as possible, and need only be lifted and replanted when the bulbs become overcrowded after several years in the same position. The bulbs are typical of a class quite distinct from that to which Tulips belong, for the old roots do not come clean away from the base, and bulbs of this type start growth again very early in the season and should, therefore, never be out of the ground for any length of time, whereas Tulips are best when lifted in July and kept warm and dry until they are replanted in November.

For naturalising in glades and woods, there is nothing better than Galanthus nivalis itself, though it seems to be undoubtedly true that it is a fastidious plant as regards soil. Where it

A SEA OF SNOWDROPS IN WOODLAND.

Digitized by Google

does well, it increases rapidly both by seeds and by offsets, and, where it does not thrive naturally, it seems to be impossible to provide the necessary conditions. The most that can be done is to provide plenty of well decayed humus by digging in and top-dressing with leaf-soil, and the position chosen should be as cool as possible, so that the foliage may be encouraged to persist after the flowers are over. If the bulbs are planted in rough grass, where the flowers always look well, the grass must on no account be mown until the Snowdrop leaves have turned yellow. Bulbs depend on their leaves for their nourishment, and no plant can build up a strong flowering bulb for the following season when its leaves have been cut off while they are still discharging their duty of transforming into stores of food the juices which they draw up from the soil through the roots.

Where the common Galanthus nivalis is happy and seeds freely, variations appear among the seedlings, and among them will probably be some double forms. Similar variations are also found among wild plants growing under natural conditions. One of the most distinct of these is a form found growing near a tributary of the Rhine by Scharlock in 1868. In these there are two peculiarities. As may be seen in the illustration, the outer segments are tinged with green, whereas in the typical plant it is only the short inner segments that are tipped with green. A further difference is that in the variety Scharlocki the spathe, which encloses the bud, splits into two leaf-like halves, whereas in the typical plant it remains joined together by a white or transparent membrane.

Another variation from the ordinary type consists in the change of colour in the ovary and in the markings on the flower from green to yellow. These yellow-flowered forms have appeared from time to time in places in the North of England, where the Common Snowdrop flourishes exceedingly; but, though they live on in the care of the specialist, they do not appear to be robust enough ever to become common.

A good position for some of the small early-flowering bulbs is under deciduous shrubs, where the branches are not allowed to grow so close to the ground that they will destroy the foliage of the bulbs when they are swept backwards and forwards in a gale of wind. In such a position, near the front of a shrub border, it is well worth while to plant Chionodoxas, Scillas and Muscaris. However, bulbs may be used anywhere. With a little experience some bulbs will be found suitable for almost any position, where they will vary the dull monotony left by winter.

THE BRILLIANT IRIS ROSENBACHIANA.

THE EASIEST FORM OF IRIS RETICULATA—I. R. CANTAB.

ABOUT ANDROSACES

SEVERAL of the high alpine species of this fascinating genus are not so difficult to grow as is generally imagined, and alpine-house treatment will overcome a lot of the difficulties usually encountered by the amateur. Even such species as A. helvetica, A. Chamæjasme and A. glacialis will give ample reward when grown in pans in a mixture of sandy peat, leaf-mould and plenty of chips. A number of the kinds which do not care for lime can be very successfully grown if planted in a scree mixture composed of pounded up slates and a little soil.

One of the rarest and most beautiful of the Aretia section of Androsaces is A. Charpentieri, which is found only on a few summits above Como and Lugano in Italy. It is one of the least difficult to cultivate, and is delightfully pretty when in the spring it throws up many little downy flower-stems, each bearing one rose pink flower. So long as the soil is light and well drained it will present no difficulties in the way of culture.

One far more intolerant of naturalisation in this climate is A. imbricata, which stands for the extreme type of this section. It is an entirely granitic species which has a fairly wide distribution, descending through the Pyrenees to the Sierra Nevada. It seemingly spends its life taking sun baths in the hottest and hardest granite precipices it can find, and when it is, with great difficulty, prised from its rocky home and placed in the choicest part of the scree, it repays all kind attentions by miffing off as quickly as possible. Except as a rarity, however, it is hardly worth cultivating, for its rather small flowers, though by courtesy termed white, are in reality of a dirty yellowish colour.

Another, and perhaps the best-known favourite of all, is A. helvetica. It is an admirable species for pan culture, and does well when rammed into a crevice in a limestone rock. It is a picture to delight the eye when, in its flowering season, it covers its grey-green mounds with the milky white flowers sitting close on to the cushion, and it presents no great difficulty if excessive moisture is kept from the foliage during the winter months, and this is a precaution which should be taken with nearly all the Androsaces in this, to them, unwholesome winter climate.

Turning to quite a different group, namely, the Chamæjasme section, we come to such old favourites as A. sarmentosa, A. lanuginosa, etc., which so long as they have a cool, well drained soil will make themselves quite happy in the most exposed rock garden. Although it is generally considered necessary to protect A. sarmentosa and its forms with a pane of glass in the winter, I think it is superfluous, as I know several gardens where it is thriving and multiplying itself and receives no protection whatever.

A. foliosa, or I should say A. strigilosa, for this is nearly always sold under this name, the true A. foliosa being much rarer and also much less beautiful, has leaves 3ins. to 4ins. long, blunt and oblong; the flowers are produced in a head, each on a longish footstalk, and are of a lilac-mauve colour. Though not particularly beautiful, it is perfectly easy to grow in any cool rich soil.

I have, of course, touched on only a few of the best known and favourite kinds, and hope to be able to mention more in some future note. ITHAW.

CORRESPONDENCE

EUCRYPHIA PINNATIFOLIA.

MUCH has recently been written in praise of this delightful shrub, so beautifully depicted in Sir Herbert Maxwell's new book, and I can safely hazard the opinion that in no case has its praise been sung too loudly. It is a superb thing, but intending planters would do well to bear in mind that it strongly resents removal, and that all the more so the older it grows. It is therefore well to secure the shrub young, preferably from seed. The planter must possess his soul in patience, however, as he need scarcely look for any bloom until about ten years after the seedling state. Far be it from me to discourage likely planters, but Eucryphia pinnatifolia has a most exasperating trick, like some of the Clematis family, of suddenly dying, without any apparent reason, long before it reaches its teens. This, I think, is sometimes caused by the heat of the sun's rays on the soil about its roots, which, however, can easily be obviated by some carpeting plant, such as one of the Saxifrages or some member of the Heath family. The plant, at least in its younger stages, prefers a moist, peaty soil, and it is well worth untold trouble to establish. As it ultimately attains a height of some 15ft. and several feet in diameter, and is very unlikely indeed to survive any attempt at shifting, it is obvious that future developments must be carefully considered when selecting a spot for it. I know of one garden in the South of Scotland where there is a magnificent specimen, and crowded against it is an equally fine plant of Crinodendron Hookeri (Tricuspidaria). It must indeed be a sad struggle for the owner to decide which is to be sacrificed, for certain it is one must meet this fate. Personally, I would not like the task. It is now more than sixty years since this Eucryphia was introduced into England and, considering the comparatively few specimens one sees and that everyone who has seen it has, possibly, tried to grow it, there is evidently considerable difficulty in establishing the plant; but that ought not to deter the enthusiast in the struggle to do so for some twenty or thirty years at least. Personally, I have just about completed my course of thirty years' struggle with the Tree Paeony and Gentiana verna, and am on the verge of owning defeat.—FORMAKIN.

A DWARF BUDDLEIA.

SEVERAL of the variations of Buddleia variabilis have received distinctive names, but most of them are tall, strong-growing plants that require a considerable amount of room for their full development, and this notwithstanding the fact that they may be cut hard back every March. In small gardens they cause inconvenience by the amount of space they require. This does not apply to B. v. houdoensis, of which the average height is 3ft. The leaves also are smaller than in the type, while the dark purple flowers are attractive. The spikes of bloom are short, in conformity with the rest of the plant, but they are freely produced and make the bush quite gay. Here, then, is a variety which is suitable for small gardens or even for restricted positions in large ones. There are people who would like to see the long spikes of bloom on the dwarf plant, but there is a fitness in proportion, for the dwarf plant is really ornamental as seen growing at Wisley.—HORTULANUS.

HELICHRYSUM FRIGIDUM.

MANY justly admire Helichrysum bellidioides with its spreading carpet, thick-set with its daisy-like flowers, but it is a plebian compared with the exquisite little H. frigidum, which far surpasses it in charm. This, however, is less responsive to our wooing in the garden and wants to be coaxed and coddled before it is prepared to reveal to us its loveliness or even, indeed, to favour us by settling down in our gardens among our well beloved treasures. Little wonder, then, that it is rare in gardens and nurseries and that the happy possessor of a healthy plant is prone to plume himself upon his success in pleasing this coy little beauty. It has baffled many, yet it is not impossible to cultivate it if we strive seriously to suit its fancies. It wants, for one thing, a dry, sunny sloping bank with plenty of sand and old mortar rubbish in the compost and thoroughly well drained. Then when late autumn draws on, it calls for shelter from our wintry rains and sleets and is only happy when these are warded off by a bell-glass, small cloche or a simple sheet of glass big enough to throw off the rain all round. There this little plant—for it never spreads much—should live happily, and form a tiny tuft of growing, glaucous leaves, yielding in summer on 2in. stems miniature Daisies of a bluish white. I am strongly of opinion, from my own experience, that nothing suits Helichrysum frigidum so well as a dry moraine sloping to the south and in full sun, with plenty of lime rubbish among the material of the moraine. Such a little flower, so full of charm, surely deserves unstinted admiration and every effort to make this Corsican beauty at home in our gardens. —S. ARNOTT.

PEACHES OR PLUMS?

THE Plum seems to me to be insufficiently appreciated in this country as a dessert fruit. The man with a small garden is too apt, if he introduces Plum trees at all, to plant the coarse and comparatively worthless Victoria, the fruit of which, though useful for some purposes, can readily be purchased, whereas really choice dessert Plums take some finding in the shops. Again, if the question of fruit under glass comes under review, Peaches and Nectarines seem always to be chosen, and there are many gardens where quite a number of trees of Persica are grown, where no Plums are grown under glass, yet a really first-class Plum, well grown, is certainly as good as any Peach and provides a very welcome change. A few good varieties include Jefferson, Kirke's, Comte d'Althan's, Golden Transparent, Reine Claude de Bavay, Bryanstone Gage and Rivers' Late Orange, but readers who have proved them will perhaps suggest other first-rate sorts for the purpose. The subject seems to be one of some interest.—S. O. K.

PLUM RIVERS' LATE ORANGE AS AN ORCHARD-HOUSE TREE.

WHAT ARE ALPINE PLANTS?

I AM glad Mr. H. Stuart Thompson asks the above question, and must admit that most of us—not only the "hardy plant nurserymen"—are sinners as regards the misuse of the term "alpine plant." Mr. Thompson admits that the question is unimportant, and from the purely amateur gardener's standpoint I quite agree that this is so. Of course, Mr. Thompson's point of view is that of the botanist—a vastly different thing. However, may I suggest that the subject is so very interesting, especially while we are considering the "Fifty Best Alpines," that a discussion upon "What is an Alpine?" would be the means of raising very many points that could not fail to have their educational value. In my list of fifty alpines, certainly very many should be strictly called rock plants. M. H. Correvon, I think, has the best title, "The Plants of the Alps for our Gardens." A correct definition of alpine plants would be very difficult to establish. In the next spring and early summer (1924) we purpose making a journey across the Grisons of Switzerland, making the capital, Coire, our centre, working both branches of the Rhine and across the border to the Rhone Glacier, by the Furka Pass, our purpose being to make a survey of the "alpine flowers"—shall we modify this to the "wild flowers of the Grisons," which certainly covers all types of plant?—returning by the valley of the Inn to the National Park of Switzerland. (M. H. Correvon specially recommends these regions for the study of wild life.) Thence across the Bernina range to the Gambrena glaciers, the Bernina lakes, Lake Nero and Lake Bianco-Glaciers, streams flowing to the Po and the Danube.

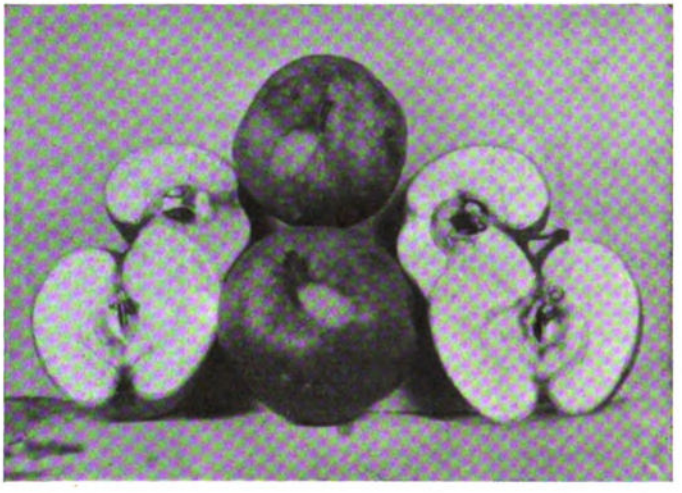
Digitized by Google

Here, among passes upwards of 9,060ft. above sea-level and summits over 13,000ft. one may find the homely Nettle, Coltsfoot, Willow Herb and the Opposite-leaved Saxifrage. The Nettle follows the hunter or shepherd wherever he makes his home —no matter how rude the hut—the other three plants nestling in perfect health among the rough moraine left by the retreating glacier. Here, in Cheshire, the Coltsfoot is also a pioneer plant, claiming the sterile soil recently deposited by the Ship Canal dredger, fixing the sandy wind-swept sand dunes with its strong underground roots and soon followed by the Willow Herb, changing this waste into a beautiful garden; and, in company with countless other grasses and wild flowers, transforming this sterile soil into humus. Many of the wild flowers found here grow also upon the high Alps. Saxifraga oppositifolia is also found in Yorkshire, Ireland, Scotland and Switzerland. On the other hand, when we consider latitude instead of altitude, "A Summer in Greenland" will give one plenty of room for thought. This little book is the work of Professor Seward, Professor of Botany at the University of Cambridge. In these Arctic regions, to name only a few "alpine flowers" (?) are Campanula rotundifolia, Butterwort, Salix herbacea (the smallest tree in the British Isles). Here also are Willow Herbs closely allied to British species, Poppies and brilliant coloured Dandelions. Again —and here we seem to have a real genuine alpine— Phyllodoce cœrulea occurs in Greenland, Iceland, Scandinavia, Scotland, Japan, Labrador and America. Still, passing strange, "Phyllodoce may have begun its existence in the Northern Pacific regions long before the Glacial period." But why does it not occur in Switzerland? This little book is a surprise in many ways, and one wonders how we are to arrive at a satisfactory working nomenclature, especially after such passages as the following: "By comparison with the variegated carpet of flowers that brighten an Arctic landscape"—and many of these are represented in our British flora—"the ground of a tropical forest is intensely gloomy." "It is a noteworthy fact that among the flowering plants recorded from the country (Greenland) as a whole, only one or two are peculiar to Greenland." It is a complex problem, and I think we must all agree with so great an authority as Mr. Stuart Thompson and in the future call our treasures "rock" plants, and even then a fresh difficulty presents itself—what is a rock plant? For my own part as a modest amateur villa gardener I give it up!—JAMES PARKINSON, *Warrington.*

INTEREST IN THE MICHAELMAS DAISY.

I WELCOME Mr. Jacob's racy article on Michaelmas Daisies which appears in THE GARDEN for December 1, 1923. It surely will set folks who read it thinking, particularly those who hitherto have taken but a negative interest in these late summer and autumn-flowering plants. There is a great deal of educational work necessary yet, relative to these very charming and easily grown hardy plants, inasmuch as many sum them up as "mostly blue flowers." Need it be said, that for reasons hard to understand, there are many who love a garden, who have left Michaelmas Daisies rigidly alone and who are all the poorer in consequence! On the other hand, there has sprung up of late years a school of growers, scattered throughout the country, who are turning their attention to these wonderfully free-flowering plants, adding to their modest collections each season, and exchanging with each other as they appraise the varieties and newcomers. We have not reached the time when the more ardent spirits are desirous of forming a Michaelmas Daisy Society—that may come—but we have assuredly arrived at a stage when, among very many who own a garden, there has been manifested a new-born interest.

If I dare presume to prophesy, I would say that we are only at the beginning of things and that more and delightful varieties of Michaelmas Daisies will appear in the near future. They will not share the same fate as hundreds of Chrysanthemums now extinct, have done, because these plants under notice, neither depend upon nor do they need indoor culture. *Their extreme hardiness will be their salvation*, as we do not have to propagate from cuttings to perpetuate them, division of roots in a general way sufficing. No! it is because Michaelmas Daisies are old garden friends—as useful, indeed, to the town gardener as to the one in the country—that, as they appear now in their more lovely, varied dress, they will be made much of. We are so inclined to think of them as flowering plants that come to us in the declining days of September, and to forget that some of them reveal their beauty quite early in August and continue to adorn the garden until late in October, as was the case in the past season. Then again, we have a wealth of variety, in size and in colour of bloom, as well as in habit; some, like ericoides, noted for attractive, dwarfish growth and their multitudes of tiny flowers. We ought not to forget that the dwarf forms of these hardy plants are useful for pot culture, for cool houses or for bringing indoors on occasion. It is, I submit, in this form we shall hear more of them at the autumn shows. No plants in my garden needed less attention, no flowers in the autumn yielded so much colour for so long, and there was nothing to compete with them for huge sprays, which it was a delight to gather and give away—incidentally obtaining new adherents to their culture another year.—W. LINDERS LEA.



"THE SIAMESE TWINS."

ROSCŒA CAUTLEOIDES.

ONE still finds some doubt existing regarding the hardiness of the attractive Roscœa cautleoides, which has now been long enough in British gardens to enable us to appraise its value in this respect. No doubt there are several places where it has not been a success, but these seem to be few and far between, and a proportion of the failures reported from these gardens may probably be due to some untoward circumstance, such as falls to the lot of many undoubtedly hardy plants when first introduced to a garden and by which other kinds of plant may be unaffected. One finds, time and again, that individual plants fail, and that with new genera or species it may be only after several trials that one can say with any confidence whether a certain kind will or will not grow in a specified garden. With regard to R. cautleoides the general experience appears to be that it is hardy and easy if planted in light, well drained soil and that there it will survive and flourish. In certain gardens with a stiff, retentive soil and in the colder parts of the United Kingdom, it may be desirable as has been recommended by some, to lift the tuberous roots in late autumn and store them during winter for replanting in spring. This is unsatisfactory and, where it has to be adopted, detracts very greatly from the usefulness of a charming plant, which, with its pale yellow flowers, is so distinct from our other garden treasures that it is coveted by all hardy plantsmen who ever see it flourishing in a border or rock garden in the well drained, sandy soil conditions which it evidently enjoys.—S. A.

FREAK APPLES.

I ENCLOSE a photograph of two "Siamese twins" Apples. One pair was just like one Apple with two cores, while the other pair was merely joined together, the area of attachment being approximately ¾ in. × ½ in. I noticed a picture of a Savoy leaf, shaped like a trumpet, in a recent issue of THE GARDEN, and thought the Apple picture might interest some of your readers. —E. W. R. BROOKS.

[The malformations shewn are of types by no means uncommon, the double-cored fruit resulting from a malformed (fasciated) blossom, and the pair with the small area in common very probably being merely "inarched" through close contact when small.—ED.]

A CHARMING WOODLAND PLANT.

FOR associating with Pyrolas, Gaultherias and other lowly peat-loving plants, Jeffersonia diphylla is a delightful little plant. This is a native of North American woods, its flowers bearing some resemblance to those of the Blood-root (Sanguinaria canadensis), while its leaves suggest an Epimedium. The blossoms are white, about 1in. across, and borne singly in spring on a stem less than 1ft. high. J. diphylla will prosper in almost any cool, vegetable soil that does not get too dry in summer. Peat is not essential, a good bed of leaf-mould and woodland loam being sufficient. A shady position is desirable. A much rarer and even more lovely but less easy species is the blue-flowered J. dubia of Manchuria.—T. H. E.

CATHCARTIA VILLOSA.

THIS is a handsome woodland plant, allied to Meconopsis and bearing some resemblance to the Greater Celandine (Chelidonium). Its pale green, deeply lobed leaves are covered with silvery hairs, and from a rather flat tuft of foliage the plant throws up a branching stem to a height of 18ins. or so, bearing in summer pretty, yellow, poppy-like flowers of delicate texture. This is not a plant of difficult culture in any cool but well drained vegetable soil. It appears to prefer half-shade, but is liable to suffer when there is much drip from overhanging trees. It is a native of the Himalayas.—L. N.

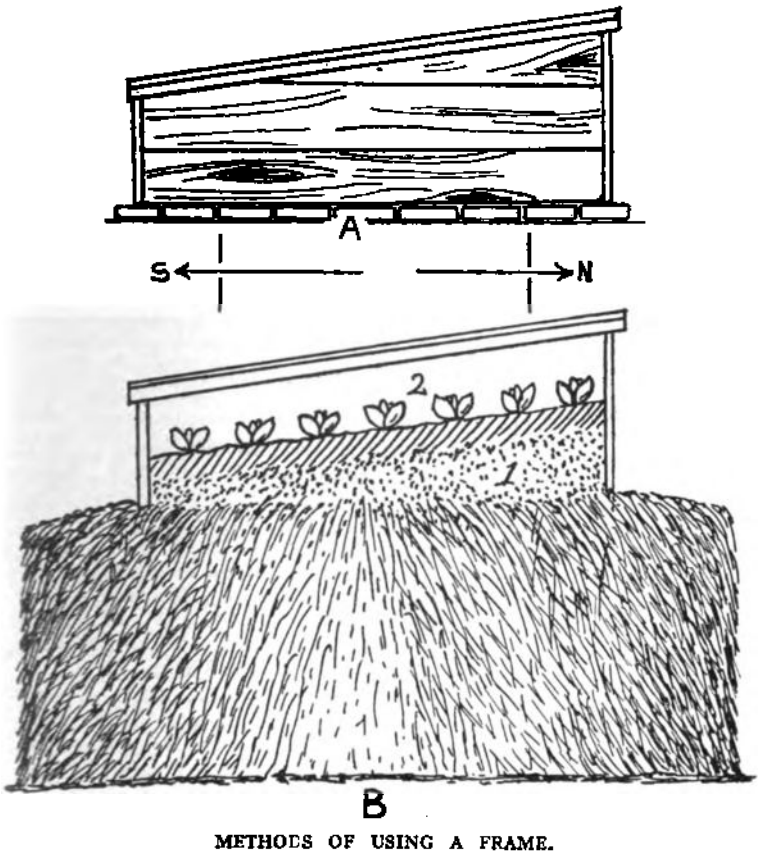
FORCING VEGETABLES IN A COLD FRAME

EARLY vegetables brought on in a little heat should be very tender and be much appreciated accordingly. They may not be large, owing to the somewhat crowded conditions under which they are grown, in comparison with those grown in the open border, but almost every part of vegetables grown under glass may be utilised, so there is no waste.

There are thousands of suitable cold frames in gardens throughout the country, and, with judgment and forethought, many tons of early vegetables may be grown in them during the first months of the year. The frame taken for granted, the cultivator should procure litter and leaves, old soil rather finely sifted, empty bags, mats or tiffany and a few empty boxes about 16ins. deep, the latter to be used to ensure the blanching of certain produce, while the full light is needed for the benefit of other occupants of the frame.

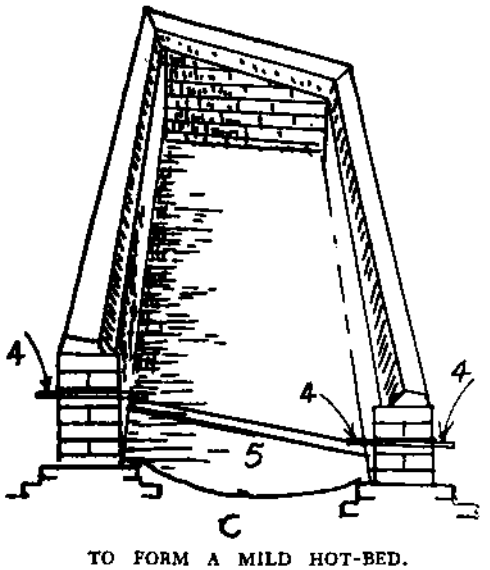
An ordinary wooden frame is very useful, as it may be moved from place to place and can always be fixed so that the maximum amount of sunshine reaches the vegetables in it, whether the frame be on level ground, as shewn in the sketch at A on a single layer of bricks, or on a hot-bed as shewn at B. The ideal position is one facing due south, or south-south-east. A brick or permanent frame must be made the best of, whether suitably or unsuitably placed.



METHODS OF USING A FRAME.

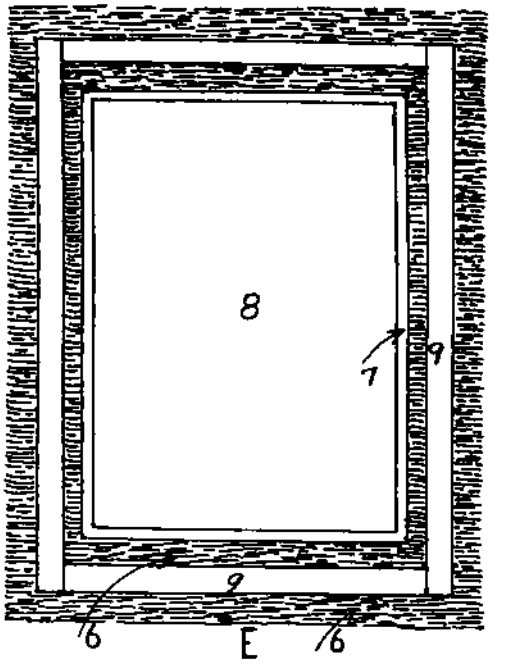
Litter from stables and last autumn's tree leaves, used at the rate of two-thirds of the former to one-third of the latter, will form a useful hot-bed. The bed should be 18ins. wider on all sides than the frame to be placed on it. Fig. B shews bed, frame and soil in section. Shake out the litter and lightly build up the bed 5ft. high; it will gradually settle down to half that height. No. 1 shews soil placed on the bed and No. 2 Lettuces planted. Several kinds of vegetables may be grown in a bed of this kind at the same time.

In a cold pit, whether of bricks, stones or wood, as shewn at Fig. C, it will be of advantage if some of the old soil is removed as shewn at No. 5, so that a mild hot-bed can be made inside to the height indicated by the Arrows, Nos. 4, 4, 4.



TO FORM A MILD HOT-BED.

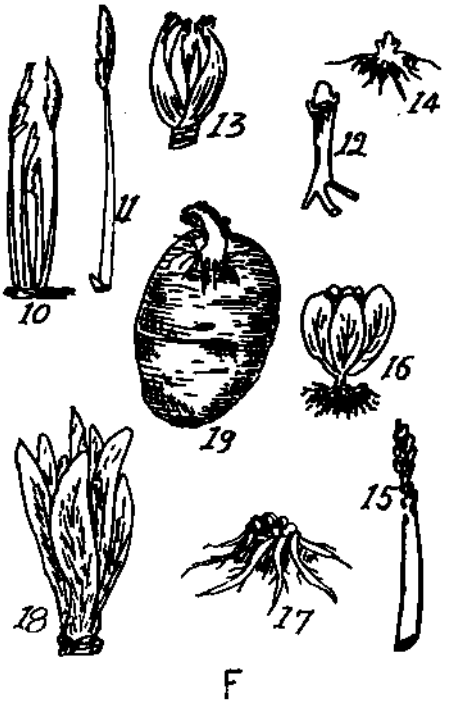
Fig. E shews the surface or top of a hot-bed; Nos. 6, 6, hot-bed portion outside the frame; No. 7, the outline of frame; No. 8, inside of frame; No. 9, broad boards placed on the bed for the cultivator to step on while attending to the vegetables inside and so prevent the treading away of the bed itself. Fig. F will shew the inexperienced amateur how to deal with some of the vegetables. No. 10, Rhubarb fit to pull; No. 11, how to pull, not cut off, the stalks; No. 12 shews a good, strong Seakale crown, and No. 13, how to cut the growing blanched tops. No. 14 shews the right kind of Asparagus root to lift and plant in a frame, and No. 15, the Asparagus cut well below the soil level; No. 16 represents a Lettuce plant suitable for transferring to a bed from a box; No. 17 shews a clump of Rhubarb possessing plump crowns (clumps with small crowns are almost useless); No. 18, Chicory grown to the stage when it is fit to cut; No. 19, a Potato set possessing one strong sprout, the right kind to plant. Sets without any sprouts or having very thin, long ones are unsuitable.



PLAN OF FRAME ON HOT-BED.

Autumn-raised Lettuces do remarkably well in a bed of rich soil in a cold frame without hot-bed assistance if they are carefully lifted and replanted in the frame about 8ins. apart every way. Maintain cleanliness of soil, ventilate when the weather is not frosty, and cover carefully to exclude frosts.

Three crops may be grown at the same time in one frame; the bed of soil should be 1ft. deep on a mild hot-bed. Potatoes, well sprouted, should be planted 1ft. apart every way and 3ins. deep; then sow very thinly seeds of French Breakfast Radishes and of an early Cabbage Lettuce and lightly cover. In a short time the seedlings will appear and will be cleared before the Potatoes are large enough to lift. Earthing-up of the Potatoes is not necessary. Carrots grow rapidly on a mild hot-bed and in fine soil 9ins. deep. The early forcing horn or stump-rooted



SOME FORCING VEGETABLES.

Digitized by Google

sorts should be selected; thick sowing is fatal to success, so broadcast the seed thinly. Carrots always thrive best and form the best roots when it is possible to expose the young plants to the wind.

Cauliflowers may be grown to maturity in cold frames where the latter can be spared. Young plants, however, do well in a cold frame if transplanted 4ins. apart in a bed of soil 6ins. deep. They require plenty of air on all favourable occasions in readiness for the final planting in the open border in April.

Early Onions and Leeks should be raised in the cold frame. The most economical way is to sow the seeds thinly in boxes and, later, transplant the resultant seedlings in a bed of firm soil at least 6ins. deep. Long White Frame Turnip is as easily grown quickly in a cold frame as the Radish; the only difference in treatment is that the soil should be firmer.

Mustard and Cress should be sown once a fortnight at this season. Seeds may be sown in rich soil in boxes or in beds. Water the flattened surface with the aid of a fine-rosed watering-can and immediately scatter the seeds on thickly and evenly, pressing them into the wet soil with a piece of board, but do not cover them.

The first sowings of Tomato seed should be made late in January in boxes or pots; in February sow seeds of early white Celery and Cucumbers, and late in that month seeds of Vegetable Marrows, one seed in each small pot, plunging the pots to their rims in the warm bed. Very careful watering is essential where seedlings of all kinds are concerned and equal care in providing ventilation. Grow only early-maturing varieties of vegetables and salads. Light is essential in the case of young plants, and care should be taken to remove covering material when this is not needed to exclude frosts.

The crowns of Asparagus should be buried about 3ins. under the soil; but Rhubarb, Seakale and Chicory crowns should be kept on the surface and the new growths blanched by excluding the light. The roots under the soil may almost touch each other.

Early Peas and Broad Beans raised in pots or turves in a cold frame where the border soil is cold and clayey ensure crops in advance of those from open-air sowings. GEORGE GARNER.

THE NEW FOREIGN ROSES OF 1921

OF the new foreign Roses of 1921 those of M. Pernet-Ducher have already been repotted upon, and of the rest, though numerically they are strong, there are very few which can be considered superior to our home productions.

ALICE KÆMPFF (H.T., J. Felberg Leclerc).—Origin General McArthur × Radiance. The blooms are pale pink and flat, the buds small and rather pretty. It is a free bloomer, the foliage is large and good, and the height about 12ins. It is fragrant.

BLANCHE AMIET (H.T., E. Turbat and Co.)—The blooms are light salmon with a coppery centre, resembling, but not so good as Mme. Butterfly, and are quickly spoilt by rain. The foliage is good and the height about 18ins It throws good autumn blooms.

CECHOSLAVIA (V. Berger).—Origin Pharisäer × Mme. Antoine Mari. The blooms are too much like Pharisäer and no improvement on it, as they have the nasty habit of going dirty. The foliage is large and light coloured, the growth strong, and the height about 18ins.

EDOUARD BEHRENS (H.T., W. Kordes).—Origin Richmond × Admiral Ward. The blooms are of a rich crimson colour and very bright, but lose colour quickly. The foliage is good and clean and the height 15ins.

ELISABETH MUNCH (Dwarf Poly., Munch and Haufe).—This is a sport from Orleans with blooms deep pink to red; not a true sport, however, for it throws back to Orleans and does not beat it. It is a big grower, too high for a "Dwarf" Poly., but no novelty and no improvement on what we already have.

FLORE BERTHELOT (Dwarf Poly., E. Turbat and Co.).—This is described as a lemon yellow, but we could only get discoloured white blooms from it. The growth is stunted and poor—quite an undesirable, in fact.

FRAU FELBERG LECLERC (Pernetiana, J. F. Leclerc).—The rich yellow blooms are quite pretty, but it is not a strong grower. Souvenir de Claudius Pernet is far better. The shoots grow almost horizontally.

HEDWIG KOSCHEL (Dwarf Poly., Munch and Haufe).—Sport from Ellen Poulsen. These so-called sports of existing standard varieties are quite overdone. This is not so good a grower as Ellen Poulsen and by no means so clean a bloomer. The blooms vary from pink to creamy white, and the foliage is spotty.

HUGUETTE VINCENT (H.T., Chambard).—The blooms are thin, but produced in big trusses. They open red shaded yellow, but quickly turn bluish pink, and the foliage rusts. It is a good grower, about 24ins. high.

JOSEPH GUY (Dwarf Poly., A. Nonin).—This is yet another bright red Polyantha, growing 18ins. high. The trusses are good as regards size, but unreliable in colour. The buds are bright red and promising, but the blooms lose colour quickly. There is no call for such so-called new Roses.

JULIANA (Dwarf Poly., H. Den Ouden).—This is an absolute counterpart of Coral Cluster, being also a salmon sport of Orleans. Registration of names is imperative to prevent two identical Roses being placed on the market at the same time and under different names.

KLEINE LEO (H.T., J. Timmermans).—This small dark red buttonhole Rose carried its blossoms singly. It is a pretty little thing with foliage somewhat inclined to mildew. The height is about 15ins.

LOUIS BOURGOIN (H.T., F. Gillot).—The flesh-coloured blooms are quite shapeless and the growth stunted, so that this is quite an undesirable and useless novelty.

LOUISE KIESE (H.T., H. Kiese).—The pretty golden yellow blooms resemble Melody in shape; the buds are particularly pretty. The growth is clean and strong, and about 24ins. high. It is worth trying another year.

MME. ADOLPHE LAFONT (H.T., J. Croibier).—The blooms are apricot red, the buds small and pointed and best in autumn. The foliage is reddish and the growth about 12ins.

MME. ALEXANDRE DREUX (Pernetiana, Soupert and Notting).—Origin Rayon d'Or × Primrose. The orange-coloured blooms are very small and the growth fair. This is not wanted.

MME. ANDRE CHARMET (H.T., J. Croibier).—Origin Mme. Mélanie Soupert × Mme. Maurice de Luze. The blooms are rose pink and the foliage mildews badly. The growth is strong and about 30ins. high, but there is no call for such a Rose, which represents no improvement on existing varieties.

MME. FEARNLEY SANDER (Pernetiana, Ketten Frères).—Origin General McArthur × Rayon d'Or. The blooms are carmine with yellow base, and are flat or globular in shape. The variety, which is liable to black spot, has erect, but not vigorous growth about 12ins. high.

MME. MERCIER DE MOLIN (H.T., A. Schwartz).—Origin Comte G. de Rochemur × Liberty. A small buttonhole Rose, this has deep pink blooms, and there is no call for it as such. The foliage rusts. It grows about 18ins. tall.

MEMEE AZY (H.T., F. Gillot).—Origin Etoile de France × Le Progrès. The deep pink blooms are small and globular. It has no qualification as a novelty. The growth is tall, reaching about 30ins.

SOUVENIR D'ANTONIER PONCET (H.T., A. Schwartz).—Origin Mme. Maurice de Luze × Lady Ashtown. The buds are quite pretty and deep pink in colour, and the blooms almost exactly like our old friend Konigin Carola, and nearly all come with split centres. The height is about 15ins.

SOUVENIR DE JEAN CROIBIER (H.T., J. Croibier).—Origin Mme. Mélanie Soupert × Lyon. The heavy blooms are of Lyon type, but paler. It should make a good exhibition Rose. Its height is about 24ins., and it has dark leathery foliage.

SOUVENIR DE MME. GAUTHIER-DUMONT (H.T., G. Gillot).—This throws clean velvety scarlet fragrant blooms and makes excellent and erect growth. It is almost too big for a bedding Rose, as the growth runs up to 4ft. high. It should be worth trying as a standard, as the growth is freer even than that of Griiss an Teplitz.

SOUVENIR DE RENE GROGNET (H.T., C. Chambard).—The large full coppery orange blooms are of a good clean colour, and it is a very strong grower. The foliage is dark and tough, of Pernetiana type, and the height 24ins.

SOUVENIR DE SERGENT CUTTE (H.T., C. Chambard).—A seedling from Mme. Mélanie Soupert, this has pretty blooms, rather a bronze than yellow. The foliage is tough, the height about 24ins., and it is not very free.

VICOMTE MAURICE DE MELLOR (H.T., Ketten Frères).—Origin Earl of Warwick × Sunburst. The semi-single blooms are pinky apricot in colour. The foliage mildews and it can hardly be considered novel. The height is about 24ins.

VICTOR MAYER (H.T., Buatois).—This is a buttonhole Rose with small blood red blooms carried singly. The height is about 18ins.

VULCAIN (Dwarf Poly., E. Turbat).—A bicolour Polyantha, pink and red mixed, this is not a desirable new Rose at all.

YVETTE (H.T., Buatois).—Origin Mrs. T. Hillas × Mme. E. Herriot. The blooms are salmon yellow, but shapeless, and the growth weak.

Of the above twenty-nine varieties there is practically nothing worth calling a novelty, nor one that is any improvement on existing varieties. The only exception to which we have taken a slight fancy is P. Gillot's Souvenir de Mme. Gauthier-Dumont, which looks to be a free-blooming scarlet Rose, though fitter for the shrubbery than as a bedding variety.

We shall give several of them a second year's trial, but so far as can be at present seen there is nothing striking about any of them, and probably the bulk will have to be discarded and blotted out for something better.

Oxted. HERBERT L. WETTERN.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—In addition to the seeds sown in the open in March we make a practice of sowing a little seed of selected Ailsa Craig during the present month, and from this batch, with just ordinary cultivation, we get some really fine bulbs. Pans or boxes, are filled with a mixture of loam and leaf-mould in equal parts with a moderate sprinkling of sharp sand added. Sow the seeds thinly: this is most important, or the seedlings will be weak and spindly. Before sowing takes place the soil should be made moist; then, if the pans are covered with a sheet or two of paper, water may not be needed until germination is effected. Arrange the pans in a heated pit, and when the seedlings appear keep them near the glass. Gradually harden them off until they occupy a position in a cold frame from which frost is excluded. Here they may remain until the time arrives for transferring them to their permanent quarters. If thought desirable and space is available, they may be pricked off in boxes containing light soil. The seedlings should be about an inch apart. Personally, I always keep them in the seed boxes until they are planted out in the bed. They should, however, be grown as cool as possible.

Seakale.—Where this crop has not been lifted, the roots should be covered with pots or boxes and then the spaces between filled up with long manure and leaves. It is necessary to exclude all light, because unless the leaf-stems are thoroughly blanched the crop will be spoilt. Rhubarb may be treated in a similar way.

Lettuce.—It is too early to sow in the open ground, but a small variety, such as Tom Thumb, may be sown in boxes and placed in a warm house until the seedlings appear. A gentle hot-bed is also suitable for raising Lettuces, Radishes, and Mustard and Cress.

The Flower Garden.

Antirrhinums.—These plants have rapidly come to the front for bedding purposes and for producing a display in the borders. To have good strong plants for putting out in May the varieties should be selected and the seed sown during the present month. Boxes or pans should be chosen and filled with a light compost. Make the surface firm and level, sow the seeds thinly, and just cover them with fine soil. Arrange the boxes in a warm greenhouse, and directly the seedlings appear, raise them well up to the roof glass to keep them short and sturdy. Overwatering should be guarded against, and a watch should be kept for woodlice, as these pests will devour the seedlings just as they appear through the soil. There are dwarf, medium and tall varieties, and for general bedding the medium are the most suitable.

Verbenas.—At one time these plants were largely increased by cuttings, and even now this mode of propagation should be resorted to if it is desired to increase the stock of any particular variety, but for everyday requirements, where a good show of bloom is needed, plants raised from seeds are the best. Seeds may be sown at any time during the next three months, but if they are sown now a warm greenhouse will be required. Verbenas are often ruined by green and white fly and mildew. Excessive heat predisposes to all these troubles. If mildew appears, dust the leaves with flowers of sulphur, and for aphis fumigation is necessary. When the seedlings appear they should be pricked off in boxes of light soil or potted singly, and they should be grown as cool as possible. Many of the varieties offered can be relied on to come practically true from seed.

Newly Planted Trees and Shrubs should be examined to ascertain if they have become loose in the soil, and, where necessary, the soil should be made firm. Labelling trees, shrubs and herbaceous plants should receive attention and stakes be prepared for use later on.

The Hardy Fruit Garden.

General Work.—The weather during the past few months has been far from favourable for carrying on the necessary work among the fruit trees. In fact, the ground has been too wet to do any planting. Now, however, every endeavour should be made to catch up arrears. When an opportunity occurs look over the bushes of Black Currants and remove all large-sized buds. These should be placed in a basket and be burnt as quickly as possible.

Vegetables Under Glass.

Cucumbers.—In most establishments these are required as early as possible, and where a suitable house exists a start should be made. The low span-roof house is best, but a lean-to facing south is perhaps nearly as good. If the house is constructed so that a hot-bed can be made inside, so much the better. When the rank steam has escaped the seeds may be sown singly in 3in. pots. The soil should be fairly moist, but not wet, then no water will be needed until the seedlings appear. At this season it is always advisable to sow a few extra seeds, because however well they are treated some will not germinate. The temperature of the house should not fall below 60°, and during the day, with sun-heat, the thermometer may safely rise considerably. When the young plants have just filled their pots with roots they may be placed in receptacles 5ins. in diameter, using a mixture of good loam and leaf-mould. Cucumbers should never be starved, so directly the plants are ready they may be transferred to heaps of soil arranged on the stage, where they will bear fruit.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

Vegetables Under Glass.

Onions.—Both as regards avoiding the fly and having the bulbs perfectly ripened, the sooner a start is made with Onions the better. The seed should be sown rather thinly in ordinary propagating boxes nearly filled with a mixture of fibrous loam and "odds and ends" of soil from the potting bench, the whole to be passed through a half-inch sieve, the rough residue being placed in the bottom of the boxes. Stand these in a temperature of from 50° to 55° and keep them near the glass. Ailsa Craig and Cranston's Excelsior are the varieties to sow if big bulbs of first-rate quality are required.

Potatoes.—If extra early Potatoes are required, a start should now be made. Make up a mild hot-bed of fresh leaves, and place a single or double light frame on it. A week later cover the leaves with a 6in. layer of moderately rich light soil, and on the surface place sprouted tubers of an early variety, such as Sharpe's Express or Duke of York, in lines from north to south 15ins. apart and 9ins. apart in the lines. Afterwards cover with 3ins. of soil. No water will be required for a time. Ventilate carefully during mild and bright weather. Protect from frost with double mats and cover with a single mat every night.

Tomatoes.—A full sowing should be made for summer supply. Earthenware seed-pans are preferable to wooden receptacles. Use light soil of not too rich a character, as firm fibrous-stemmed plants are what are wanted. Germinate the seeds near the glass in a temperature of about 55°. The names of Tomatoes are legion, but Holmes' Supreme, Kondine Red, Sunrise and Lister's Prolific are all reliable varieties.

Cucumbers.—This is a suitable time to make a sowing for spring and early summer supplies. Sow in 3in. pots partially filled with fibrous loam and place in bottom-heat in a temperature ranging from 60° to 65°. Lockie's Perfection (black spined) and Tender and True are two good varieties.

The Hardy Fruit Garden.

Apples.—Mussel scale is a pest which often does serious injury to the bark of Apple trees. This is a suitable time to combat this enemy, which the uninitiated might fail to observe, as it clings close to the bark, covered by its tiny, inconspicuous, mussel-shaped scale. It can generally be annihilated by repeated syringings with a solution of paraffin at the rate of 1 gill of paraffin to 5 gallons of water. However, as this and other mineral solutions if not very carefully manipulated are apt to injure the young shoots, the best plan is to apply with a stiff brush a solution of plain yellow or white soap at the rate of ½lb. of soap to 1 gallon of hot water.

Training.—There are many systems of training the various hardy fruit trees (fan, horizontal, cordon, etc.), but in training young, partly developed trees there is one guiding principle which should be observed when dealing with the extension of leading shoots on any part of the tree, and that is when the shoot is abnormally vigorous it should be checked by being inclined downwards for the time being, the opposite policy being pursued when a shoot is abnormally weak.

Raspberries.—Although late, new plantations may yet be made in soil that has been well enriched and deeply cultivated. The old system of training five or six canes to a stake has largely given place to the better system of training the canes to wire trellises, the wires being strained on either wood or iron standards, two wires being quite sufficient. The trellises should run as near as practicable north and south and at a distance of about 4ft. apart. Superlative is one of the best varieties.

The Flower Garden.

Bedding Plants, such as Heliotropes and Salvias, which are to be increased by cuttings, should now be placed in moderate heat to produce fresh growths. Paul Crampel "Geraniums" which were rooted in small pots should be shifted into 4in. pots and placed in heat. As they are not subject to attack by pests they may be placed in the early vinery if that has been started.

Lawns.—Where a lawn is shewing signs of deterioration it should receive a dressing of light rich soil or old hot-bed manure. The material, after being passed through a half-inch sieve, should be swept in with a birch broom. All lawns should be swept and rolled occasionally, as it is only by such means that a lawn can be kept in first-class order.

The Seed Order.—Seed lists will now be to hand, and the sooner the annual order is placed the greater will be one's chance of being well served. Written or mental notes will have been made of extra good results or comparative failures with any of last year's novelties, and one should be guided accordingly. A fresh set of novelties with their strong claims will again be pressed upon customers' attention: they may be all that they claim to be, but both common-sense and experience should lead one to go warily and test them only in small quantities, relying in the main on well tried varieties.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidsoh's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

General Work.—The first week in the New Year is the best time to formulate plans for the coming season. Thus one should compile a list of seeds and also of any new plants that may be required for propagating purposes. The ordering of these is very essential if one is to have seeds and plants at hand at the time most favourable for sowing or propagating. New plants that may be required for stock purposes should be ordered, as they are often small and not in a condition to give a good supply of cuttings if left until later, whereas if they are obtained at once they can be potted on and prepared for propagation. Nowadays, plants raised from seed play a very important part in keeping the conservatory and greenhouse bright and well furnished throughout the year. Here, it may be well to note at least some of the plants that can be raised from seed and may be depended upon to give a good display in their season. There are quite a number of foliage plants that are more or less indispensable for mixing with the flowering plants, as well as furnishing a supply of plants for decorative purposes in the dwelling-house. They include such useful plants as Albizzia lophantha (syn. Acacia lophantha), Fatsia japonica (syn. Aralia Sieboldii) and F. Moseri, Asparagus Sprengeri, A. plumosus nanus and A. decumbens, the last-named species making beautiful basket plants; Coleus, Cordyline australis, Cyperus alternifolius, Eucalyptus globulus and E. citriodora, the latter worth growing for its scented foliage; Grevillea robusta and Kochia trichophylla. The latter plant is generally grown for summer bedding, but it is also very useful in the greenhouse. Hardy annuals at the present day are very important, as they are largely used for furnishing the greenhouse. Although the best results are obtained by sowing them during September, still quite good results can be obtained by sowing early this month. Some of the most useful and popular for pot cultivation are Acrocliniums, rose and white; Alonsoas; and Clarkias, of which there are fine varieties in white, pink, salmon, scarlet and purple. Collinsia bicolor, with lilac and white flowers, is quaint and pretty. The tall double-flowered Godetias in various colours are very effective and useful, as also are the tall stock-flowered Larkspurs. Mignonette is, of course, indispensable, a good selection of Machet being as good as any for pot work. Nemesias again are very charming when well grown. Salpiglossis are very beautiful, but are by no means easy to grow. Schizanthus, of which there are many fine strains, are also very popular. Here I would say that the S. retusus varieties are

Digitized by Google

deserving of more general cultivation. Statice sinuata is largely cultivated, but the more difficult S. Suworowi should be more generally grown, as it is a charming plant and lasts in flower for a long time. Lobelia tenuior is very beautiful, and should be sown in successional batches. Some of the essentials for the successful cultivation of annuals in pots are thin sowing, early transplanting and cool, airy conditions at all stages of their cultivation, remembering that any check is fatal to them. The following are some of the more tender annuals and plants of a more or less perennial character that may be raised from seed, viz., Achimenes, Angelonia grandiflora, Asclepias curassavica, Balsams, Browallia speciosa major and B. viscosa, tuberous-rooted Begonias in many varieties, Calceolarias, Campanula pyramidalis, Celsia Arcturus, Celosias, Clerodendron fallax, Clianthus Dampieri and C. puniceus, Ipomœa rubro-cœrulea, Cinerarias and Cyclamens in variety, Exacum macranthum and E. affine, Francoa ramosa, Freesias, Gerbera Jamesonii and its many beautiful hybrids, Gesneras, Gloxinias and Streptocarpuses, Humea elegans, Gilia coronopifolia, Nicotiana suaveolens and N. Sanderæ. The many varieties of Petunias give a lasting display. The Chinese Primulas are a host in themselves, but some of the others, such as PP. malacoides, kewensis, verticillata and Forbesii should not be overlooked. Rehmannia angulata is also very useful, while all the varieties of Salvia splendens are easily raised from seed. So are Tecoma Smithii, Thunbergia alata and the beautiful T. Gibsoni, Torenia Fournieri grandiflora and Trachelium cœruleum. Nierembergia frutescens gracilis and N. filicaulis are very graceful, dainty and charming, and should be more generally grown. Although the foregoing do not by any means exhaust the list, they may, perhaps, be helpful to some in making a selection for the coming season. When buying seeds it is always advisable to go to a firm of repute.

Gesnera cardinalis.—Where anyone has a stock of dry tubers they may now be started in a warm house. They succeed under the same treatment as Gloxinias; either lay them out in boxes containing light soil until they start or place them directly into small pots. During their growing season they enjoy a temperature of 55° to 60°, but when in flower will stand in the greenhouse. This plant may be raised from seed sown some time during this month, while the resulting plants should flower towards the end of summer.

Royal Botanic Gardens, Kew. J. COUTTS.

SOME OLD BUT FIRST-RATE DESSERT APPLES

WHORLE PIPPIN, a summer Apple of first-rate quality, being ripe in August, is well known in Scotland and worthy of cultivation. The fruit is below medium size, oblate, handsome and regularly formed, the skin smooth, shining, almost entirely covered with fine bright crimson and marked with broken streaks of a darker colour. The stalk is a quarter of an inch long, and set in a wide cavity, the flesh yellowish-white, firm, crisp and very juicy, with a pleasant flavour.

COURT OF WICK.—This is a valuable dessert Apple—indeed, one of the best—the flavour of the fruit being rich and delicious. It is in season from November to March. The variety succeeds on most soils, is not subject to canker, and is most prolific on the Paradise stock. The fruit is below medium size, roundish ovate and handsome, and just the right size for dessert. The colour is clear yellow and bright orange, with a flush next the sun, the surface freckled with russet. The flesh is yellow, tender, crisp and juicy.

CLAYGATE PEARMAIN.—This valuable Apple of quality ought to find a place in every garden. It is especially useful for small gardens as it produces abundant crops on the Paradise stock. The fruits are in flavour similar to a well grown Ribston Pippin, the flesh being yellowish, crisp, juicy, rich and sugary. It is of medium size and in shape not unlike Christmas Pearmain. The skin is dull yellow and green with a coating of russet and numerous dots on the shaded side and marked with broken stripes of dull red next the sun. The fruits after being stored become golden yellow with streaks of bright crimson. This is an Apple of exceptional properties and one to be cherished, as it will keep well until March.

BULL'S GOLDEN REINETTE.—This excellent and superior Blenheim Orange type of Apple is met with occasionally in the Herefordshire orchards, the fruits being firm, heavy and good. The flesh is yellowish, tender, juicy and sweet, with a fine aroma. It is a grand Apple but not generally known. Often sold in the local market as highly coloured Blenheims, Golden Harvey or Brandy Apple, the variety is fast dying out, which is a pity, as it is worth a place among the very best. Its late-keeping qualities also commend it, as firm fresh samples have been shewn at the end of May. A few old tumbling-down trees are found in the Herefordshire orchards, and no one takes care of them, yet everyone says it is just as good as Cox's Orange Pippin, the flesh being yellow, firm, crisp, juicy and sugary, with a rich and powerful aromatic flavour. The fruits are on the small side, about 2ins. across and about the same in depth. The skin is covered with rough scaly russet, the ground colour being yellow, which is overlaid with brownish red on the sunny side.

KERRY PIPPIN is a never-failing variety on the Paradise stock. Although not a late keeper, it is of good quality in its season (September—October). The fruits are below medium size, oval or roundish oval, the skin greenish yellow, changing to clear yellow, tinged and streaked with bright crimson, the flesh yellowish white, firm, crisp, juicy and sugary and of aromatic flavour. This is a splendid Apple for smaller gardens.

MARGIL.—This Apple to my mind is on a par with Ribston Pippin and Cox's Orange Pippin for flavour, as everyone who knows or grows it will testify. It excels in juiciness, aroma and flavour, and is just the size for dessert purposes. The colour is orange streaked with deep red and covered on one side with patches of russet. The fruit is conical in shape, five-sided and angular, the angles terminating at the crown in five prominent ridges.

PEARSON'S PLATE.—This is a late Apple of distinctive merit. When properly stored it will last well past March, and is, if the expression may pass muster, "as sweet as sugar." The fruit is small, roundish ovate and regularly formed, the skin smooth, greenish yellow in the shade, mottled with red and streaked with deeper red next the sun, and the flesh greenish yellow, firm, crisp and full of juice. This is a delicious fruit and ought to be extensively planted. The tree makes a good standard, and also crops well in the bush and espalier forms.

REINETTE DU CANADA.—I have often wondered why this excellent utility Apple is not more generally planted, as it possesses all the qualities of a first-rate fruit, being large in size, luscious in appearance, crisp and juicy to the palate, free in growth, prolific in crop, and has every other essential point an Apple can claim. Its keeping qualities render it valuable, too, as sound specimens have been handled by the writer in the first week in May. The skin is greenish yellow, with a tinge of brown next the sun and strewn with brown russety dots and veins of russet, and the flesh yellowish white, firm, juicy, brisk and richly flavoured. This variety makes a splendid bush and crops well trained as an espalier.

WHEELER'S RUSSET keeps until April, is a prolific bearer, with fruits small to medium in size and of rather irregular outline. The skin is pale yellowish grey russet, freckled with russet and reddish brown next the sun, the flesh greenish white, firm, juicy and sugary and with an aromatic flavour. The tree makes a large standard and is free in production.

DUAL-PURPOSE APPLES

WHEN I visited the gardens of the late Dr. Bull (Herefordshire's great pomologist) his daughter, Miss Maud Bull, pointed out to me several items of great interest, sentimental and practical, but those which interested me most were some fine Apple trees of varieties thought highly of by her late esteemed father.

NEW BESSPOOL has fruit of medium size, and the particular tree I was looking at, planted by the late owner over fifty years ago, is now capable of carrying 12cwt. to 15cwt. of fruit. This tree came to Dr. Bull from Yorkshire, and after a while many trees were grafted from it in the orchards of Herefordshire, and it is known by many of the older school as Yorkshire Pippin. The tree is a healthy grower of somewhat upright habit and insists on a "rest" season, this being one of its noticeable traits. The fruit carries a nice bloom, is about 3ins. wide and about the same in length, the skin dull yellow on the shaded side, streaked with broken stripes of pale red and dark red next the sun, strewed with russety dots. The stalk is stout and straight, inserted in a russety cavity, the flesh greenish white, crisp, juicy, sweet and of excellent flavour. One of the good points of this desirable Apple is its long keeping qualities, it being an ideal dessert fruit for those who can masticate firm-fleshed Apples. Another good point is the lateness of its flowering. It is, in fact, about the last to blossom, and appears to be self-fertile. It succeeds as standard, half-standard or bush.

Another little-grown sort Dr. Bull thought well of was WORMSLEY PIPPIN, and although not a late keeper, it is, assuredly, a valuable Apple. The tree he planted was beginning to shew signs of age, but the few fruits shewn me were as luscious looking as pretty. A seedling raised by the late Mr. T. A. Knight and brought to notice about 1811, this particular tree came to Dr. Bull from Mr. Knight's private nurseries at Tillington, a village about five miles from Hereford. Mr. Knight was born at Wormsley Grange on August 12, 1759, and no doubt his seedling was named in compliment to the old home. The fruit somewhat resembles that of the American variety Newtown Pippin, the skin being smooth, of a clear deep yellow, the fruits medium to large in size, ovate, with angular sides, which terminate at the crown in several prominent ridges. The tree is healthy, hardy, and in favourable seasons an abundant bearer; the flesh yellow, tender, crisp, sugary, with abundance of juice. I noticed that the foliage was large and of a pale green colour.

Another Apple highly esteemed by Dr. Bull was GRAVENSTEIN, and he was always emphasising its utility to his many friends. This beautiful and excellent Apple is so useful, both for kitchen use and for dessert, that it is strange more trees are not to be found in gardens. The fruits are medium in size, the skin smooth, pale yellow and streaked with bright crimson on the side next the sun, the tree a vigorous grower and free from canker; at least the tree I saw was perfectly clean. It is a mid-season variety, keeping to about the end of December if properly stored. The flesh is white, crisp and juicy, with an aromatic flavour. Miss Bull considers Gravenstein to be the best early and mid-season variety in the garden.

THE GARDEN

No. 2721.—Vol. LXXXVIII.] [January 12, 1924.

THE LABURNUMS

During May and June there are no more beautiful flowering trees for garden and open woodland than the Laburnums.

FOR small and large gardens the Laburnum is equally suitable. The trees thrive in nearly all soils, the exception being ground of a boggy nature. While the Laburnum is one of the best known of the smaller flowering trees it is by no means so freely planted as its beauty deserves. In addition to the two well known species LL. alpinum and vulgare, and the little known L. caramanicum, there are quite a host of hybrids and varieties, forming, when a representative collection is grown, an interesting and showy group of flowering trees.

The Laburnum has been so long and widely cultivated in our pleasure grounds that one is not surprised if a doubt is expressed when an interested party hears for the first time that it is not a native tree. The date of its first introduction does not appear to be definitely recorded. Under the name of Anagyris, Laburnum, and Bean Trefoil, Gerard cultivated either L. vulgare or L. alpinum in 1597. Miller, in his "Gardeners' Dictionary," was apparently the first to describe the two as distinct species. In Vol. V of the "Botanical Magazine," Tab. 176, published in 1792, the name Cytisus Laburnum is used with the proviso that "our nurseries afford two principal varieties, the broad and narrow-leaved; the latter (which is the one figured) Mr. Miller was induced to make a species of, under the name of L. alpinum."

In suburban gardens, unfortunately, many Laburnum trees come in for a share of the indiscriminate yearly pruning, hence are unable to develop their full beauty. It is as lawn trees, preferably with an evergreen background, that we can appreciate their full worth, specimens 15ft. to 20ft. in height, occasionally higher, and usually more in width, with a short, thick, often slanting trunk. This defect, if it is one, can be obviated by staking the trees for the first few years after planting.

Though so readily raised from seeds, it is, no doubt, the indiscriminate raising of seedlings which accounts for so many poor varieties being cultivated. When seedlings are grown the seeds should be gathered only from the very best forms. Grafting or budding, using seedlings as a stock, should form the main source of increase. The Laburnum is also a good stock for some of the Cytisuses, notably C. Dallimorei and the pretty standards of CC. purpureus, kewensis and Beanii.

A PLEASING CONTRAST, LABURNUM VULGARE AND A HANDSOME PÆONY.

L. ALPINUM.—The Alpine or Scotch Laburnum is a native of Central and Southern Europe, being found wild in most of the localities where the Common Laburnum grows. The name Scotch Laburnum apparently arose from the erroneous idea that a tree so long grown (over 300 years), and widely cultivated, must be a native. The most important differences between the two species are tabulated at the end of the article.

With trees so long and widely cultivated it is not surprising that many sports and hybrids have been raised, so that to-day it is not easy to determine to which species many of the forms belong, while some of the hybrids partake of the best characters, long racemes, large individual blooms and rich colour of both species.

The following varieties are usually included under L. alpinum.

Var. autumnale is so named because the trees usually develop a second crop of blossoms in autumn.

Var. fragrans is a form with more scent.

Var. hirsutum.—In this form the downy character of the leaf suggests that this may be a hybrid with L. vulgare.

Var. pendulum is a form with more or less weeping branchlets.

L. VULGARE.—The Common Laburnum is a native tree of Central and Southern Europe, which includes Southern and Eastern France, Switzerland, Italy,

Digitized by Google

Southern Austria, Hungary and Serbia. Among a large number of varieties the following are the most distinct and desirable.

Var. Alschingeri is a wide form from Eastern Europe with leaflets conspicuously downy and a two-lipped calyx.

Var. aureum, the golden or yellow-leaved Laburnum, is a novel and pretty tree when well placed in the landscape. Other names for this tree are chrysophyllum and foliis aureis.

Var. involutum, which has curled or twisted leaflets, is also named cristatum and bullatum.

Var. quercifolium.—As the name suggests, the lobing of the leaf resembles that of an Oak.

Var. sessilifolium is a form with larger leaflets which have little or no stalk.

For general garden planting it is large-flowered, long-racemed hybrids which should receive the most attention. These it is obvious must be increased by grafting to reproduce them true.

L. PARKSII originated in a seedling, obviously a hybrid, raised by Mr. J. D. Parks of Dartford. The raceme of flowers is long and notably rich in colour.

L. VOSSII has racemes of glistening pale yellow flowers in racemes often 18ins. to 22ins. long and is very free flowering.

L. WATERERI, raised in the nurseries of Messrs. Anthony Waterer, is notable for freedom of flowering, length of raceme and depth of colour.

A very beautiful form at Kew labelled "Latest and Longest," well merits the name.

L. CARAMANICUM is a little known species, a native of Greece and Asia Minor. It was first introduced about 1879 or 1880. Described as a small tree, the one or two specimens I have seen were thin bushes some 3ft. to 5ft. high. Flowering late in the season on the shoots of the year, a little shortening of the growths is desirable about March. The yellow flowers are in terminal racemes, quite unlike those of the other two species. It is figured in the "Botanical Magazine" Tab. 7898. The plant is evidently one for a sunny corner and light well drained soil.

L. ADAMI.—This remarkably interesting tree appeared in the nursery of M. Jean Louis Adam at Vitry, near Paris, in 1825. As is often done, M. Adam budded Cytisus purpureus, using the Laburnum as a stock. To his surprise one of the branches grew more vigorously and developed purplish-yellow racemes of flowers. This character he was able to perpetuate by budding or grafting. Later some of the branches of the graft-hybrid produced growths shewing signs of reverting to the two parents. Many of the trees growing in our gardens to-day develop the three types of growth and flower. I can call to mind no tree which has created so much interest among scientists, and it has furnished a theme for many writers. Though so much has been written upon the subject, as regularly as June comes round we receive at Kew flowering specimens, sometimes with novel suggestions to account for the "freak." The interest attached to the tree has evidently resulted in its being fairly widely planted for some years, if one may judge by the description of the trees from which the specimens come.

The planting of Laburnum trees in parks where cattle browse is not desirable. While trees in the woodland and pleasure grounds are frequently damaged by hares and rabbits with apparently no harm to themselves, cattle have been known to develop poisonous symptoms after eating Laburnum leaves and twigs, sometimes with fatal results, while other records tell of cattle making sumptuous meals from the trees without harm. There is a very decided risk, which is not worth taking. Children who have eaten the seeds in a green state have been violently affected with symptoms of poisoning, death even resulting in one or two instances.

A HANDSOME TREE OF LABURNUM ALPINUM.

NOTES FROM FLORAIRE

CAMPANULA ALLIONII ALBA (see Mr. C. Elliott's note in THE GARDEN, for December 8, last, page 634), is indeed a beauty. I found it in August, 1909, on a barren slope near the Lake Foréant (Haut Queyras), and we cultivated the form here and sent it over to many gardens up to 1914; we planted it in our gardens at Bourg-St.-Pierre (4,300ft. altitude), and on the Rochers de Naye (6,000ft.) and it grew there, especially on the latter, very happily. But from 1914 to 1920 we could not take care of these two gardens so that weeds invaded the rarest plants and killed our most treasured specimens. Now, Mr. Elliott seems to have ascertained that the plant has disappeared from English gardens and I believe he is right. I would advise him—he is one of the keenest of growers and collectors—to go to Lake Foréant and seek the plant again. I took only a bit of it, letting the bigger part of the plant remain.

There is at the foot of the Mont Aiguille (Dauphiné) at Les Pellats, a dazzling "pierrier" where I once found C. Allionii at its best, much bigger and more deeply coloured than anywhere else. I believe it to be what Mr. Elliott calls the Backhouse Variety. The flower is very large, not solitary, as it should be, but grouped in fives and sixes on the stems, just like those of C. speciosa in the Pyrenees, and deeper in colour than is common. At first sight I thought it was C. speciosa, but it really was C. Allionii. It was there mixed with the rare Eryngium Spinalba, with Erinus, Dryas, Primula Auricula, Globularia, and that great beauty Gentiana angustifolia.

Our Primula Allionii, which we grow on the eastern or western sides of perpendicular walls, are doing well; we grow them in limestone. They flower well, but give little seed. We ought probably to pollinate them artificially.

P. cottia, which is very near to P. villosa of the Eastern Alps, is a curious plant, covered with brown hairs, as in P. pedemontana; it is, however, more woolly and has deep carmine flowers. It wants a cliff with a north aspect, as does its companion plant, Campanula Elatines. This Campanula is one of the most curious plants I know, growing on the hardest granitic rocks and carpeting them with its long flexible trails of deep blue flowers which open in autumn. Its near relative, C. elatinoides, which I used to find all above the Presolano group in the Bergamasc Alps, has woolly and bigger foliage, larger and brighter flowers and grows in limestone rocks, always in shady places protected somewhat against rain.

Campanula Raineri grows near it, but in very sunny situations, covering barren limestone rocks exposed to the full sun. The plants spring up from the surface of the stones in such a way that one cannot determine how they take root in them. The same peculiarity is noticeable with C. Morettiana, which grows only on shady cliffs in the Tyrol; it is very difficult to extract and most difficult to grow.

The rare C. petræa, with yellow flowers, is also a rock lover and spreads by insinuating its stolons into rock crevices; they form at the surface of the cliff large, woolly, fleshy rosettes. The flowers in little heads of yellowish colour spring from the oldest rosettes in late summer.

GENTIANA ACAULIS ALBA (= G. GENTIANELLA ALBA?) AT FLORAIRE.

THE BEAUTIFUL GENTIANA VERNA CHIONODOXA AT FLORAIRE.

The white Gentiana acaulis* is seldom found in Nature. I have myself never found it, but one of our men did. It is exceedingly pretty, with the five green spots in the throat of the flower. But the white G. verna is more easy to find on limestone pastures. The flowers are pure white and

Farrer, when once he saw it here, said it should be called G. chionodoxa (Glory of the Snow). It must be given a rather light soil and sunny aspect.

G. bavarica is by far the deepest blue in Nature. The plant is moisture-loving, always growing near running water and in spongy soil in a damp but sunny situation.

The carnea group of the genus Androsace is the cause of much confusion. There are six different forms of the species, one of which (A. Laggeri) is quite a distinct plant, although the French botanists consider it merely a form of Erica carnea (see Coste Gillet and Magne, etc.). I once gave in THE GARDEN (May 16, 1903, page 333), a note with two drawings representing Androsace carnea and A. Laggeri, from which the difference is easily realised. While A. carnea grows on granitic Alps, A. Laggeri is entirely Pyrenæan. The former makes small, thin tufts of lax rosettes, the leaves of which are recurvate, slightly glaucescent and very shortly ciliate, the whole plant being pink coloured in autumn. The flower stems are upright, 2ins. to 4ins. high, each bearing a small umbel of little pale pink flowers. A. Laggeri is confined to the Pyrenees, where it replaces A. carnea and

Digitized by Google

has hitherto been considered a form of it. The Index Kewensis, of which the tendency is against setting up an unnecessary number of species, keeps it as a true species, I am glad to say. Moreover, both its aspect and its cultural needs would separate it from its congener. Seen side by side here, the difference is so clearly marked that nobody would confuse them. A. Laggeri is stoloniferous, forming sometimes patches 10cm. to 30cm. broad; its leaves are very narrow, never recurvate and often imbricate, light green, quite smooth, forming little cylindrical shoots tipped with a small rosette. The greater number of the shoots remain sterile and the others rarely bear more than one flowering stalk. Curiously enough the flower stalks are sessile when the flowers open, being attached to the end of the shoots like those of Aretia glacialis, Douglasia Vitaliana, etc. By degrees, however, the stem lengthens as well as the pedicels of the flowers, so that, after a few days they form a little rose-coloured bouquet of five to six flowers on a stem 2ins. to 3ins. high, taking on the appearance of a little Primula farinosa.

The varieties of Androsace carnea are A. puberula (Monte Viso and neighbourhood), with whitish pubescent leaves; A. Halleri, with leaves sometimes longer than in the type, always recurvate and strongly ciliate, from the Cevennes and the Vosges); A. Reverchoni from Piedmont, which is a pure white form; and A. brigantiaca, from the French and West Italian Alps, with thin, long stalks, often approaching 1ft. high, very pale pink flowers and very narrow leaves. All these are readily raised from seeds and easy to grow in light soil in sunny situations or between rocks.

"*Floraire*," *Geneva.* H. CORREVON.

[*The picture which M. Correvon sends is apparently of the white form of the Gentianella, which, we take it, could hardly be collected in the Alps. It would be interesting to know which of the five related species comprising G. acaulis *L.* throw albinos and how many of them have white forms in cultivation.—ED.]

THE TREATMENT AND PLANTING OF DRY BANKS

Some Suitable Shrubs.

HAVING for a number of years been confronted with the problem of covering the dry soil of steep garden slopes, I think some of our experiences may be of interest to the many others who are at times "up against" similar difficulties. It should be understood, however, that over a considerable portion of the ground our object has been not only to make the desert "blossom as the rose," but also, at the same time, to defeat the law of gravity as it affects a loose, gravelly soil.

In the first place, and for obvious reasons, we have always contrived to avoid, as far as possible, the cultivation or breaking-up of such areas. Rather have we endeavoured to select plants that will suit such conditions, strong-growing, drought-resisting shrubs and herbs which actually delight in exploring with their roots and binding together the gritty, often-stony, crumbling soil.

When, as in the case of the choicer Heaths, it has been deemed desirable to add something in the way of moisture-retaining material, leaf-mould has been the main stand-by, this sometimes being supplemented with old cow manure, well weathered peat moss litter and decayed vegetable rubbish. Where the slope allowed, one or other of these substances would be worked in to the subsoil prior to the planting, and the plants would also be given something of this kind about the roots in addition. In any case, one is faced with the fact when planting slopes of this description that whatever has to be done by way of improving the soil can only be carried out before or during the actual stocking of the ground. Subsequent top-dressings are a waste of time and material when one's slope is too abrupt to allow anything to lie with a fair chance of its being incorporated with the soil. If there were no birds and no heavy rains things might be different, but having an abundance of both we prefer to put our dressings underground.

Deep planting is the rule in tackling work of this kind. That is to say, most kinds are put in much deeper than would be considered desirable under more normal conditions. Then in opening the holes for any plants that allow of such treatment, the former are made at right angles to the lie of the land, not with the handle of the spade at the perpendicular. This is especially important in the case of Heaths and, indeed, there are few plants or shrubs which, in the circumstances, are not better planted in that way.

Considering first those drought-proof shrubs which will prosper in a poor, gravelly loam which has undergone no cultivation of any kind, save, perhaps, a rough surface-cleaning, the Brooms are of primary importance. We have found no ground too hot or too impoverished for these, and (unless they happen to come in pots) we always plant them, as seedlings or rooted cuttings, by simply slipping them into a deep slit made with the spade. Beyond reducing the leading stems by about one-half they get no further attention and we rarely lose a plant.

It is not necessary here to name the various kinds of Brooms which can be employed for the purpose under discussion. All of them are excellent. But the discerning will, naturally, make his selection in accordance with the dimensions and nature of the space he has to cover, since in the Cytisus group alone he has a wide choice from CC. Ardoini and decumbens, of 4ins. to 5ins., to CC. scoparius (in great variety) and albus, which may go up to 8ft. and more. In Genistas the range of suitable kinds is even greater, such superb species as GG. virgata and cinerea making 10ft. with a circumference in proportion, and then there is a whole host of smaller ones of infinite diversity, many of them producing ground-hugging mats and mounds of dense growth which are admirably suited for clothing sterile, sun-beaten banks.

These latter shrubs may, of course, be used alone, grouping the various sorts of like character together, or they may be worked in with such as the dwarfer Heaths. They also make a first-rate undergrowth, however, for any of the tall kinds of slender, sparse habit, such as C. albus, G. ætnensis and that fine old shrub Spartium junceum, all of which are liable to be rather too thin and leggy for use alone. Moreover, it has to be borne in mind that a good ground covering is half the battle in any work of this kind. And now that I am on the subject, I may add, by way of illustrating possibilities, that we have dry slopes clothed with Erica carnea, Vinca major and creeping Ivy among which the taller Brooms and other shrubs are disposed with most satisfactory effect.

BROOM, SPARTIUM JUNCEUM.

Not less adaptable for our purpose here is the Double Gorse (Ulex europæus fl. pl.), than which there is no more gorgeous shrub in British gardens. Few seem to realise how fine this is and how superior to the type. Indeed, not a few are as unfamiliar with it as the lady who, on gazing with rapt astonishment at a broad belt of Double Gorse blazing in the sunshine of last May and being told what it was replied, "But I thought all Gorse

Digitized by Google

was double!" This magnificent plant scorns the terrors of drought in the most abject apology for soil, and is quite easy, especially if put out from pots. It makes a fine background for Erica cinerea, rosea and other varieties. The dwarf, autumn-flowering Gorse (Ulex nanus) and the superior U. Gallii of the same style and habit are both useful for our purpose here. What we need, however, and what I have been waiting for for a long while is a double form of one of these, preferably the latter. Then we should have a low-growing, compact, autumn-flowering Furze which would prove of inestimable value, either alone or for use with other shrubs, such as the later Heaths.

In addition to the Ericas already mentioned, viz., EE. carnea and cinerea, we have found darleyensis equally good for dry places. Calluna vulgaris in many varieties is also happy in very hot land provided it gets away, but we find it generally needs more helping during the first season, bracken or hedge brushings being laid over it in trying weather. The dwarf form of E. scoparia makes a good ground cover in such conditions and is a useful substitute, where such is needed, for the much slower, prostrate Junipers.

Though they are often recommended for arid, sun-scorched soils, the hybrid Helianthemums do not stand up to our extreme conditions as courageously as their reputations would seem to promise. Even so they will generally prosper if given a fair start, and nothing can be gayer where a display of brilliant colour is desired. Better than any of these when resistance to drought is a first consideration is the beautiful H. formosum, a low-growing shrub which, owing to its semi-prostrate, sweeping habit, is admirably suited for growing on sloping ground. This species will, moreover, cover a considerable area with its thicket of spreading, grey-leaved branches, and the form known as H. f. unicolor is certainly not less useful and charming. After the same style but taller and more upright are HH. halimifolium and algarvense (ocymoides), and H. alyssoides, which is greener in leaf and closer in growth, is also a first-rate plant—probably the best of all the dwarfer yellows. The white-flowered H. umbellatum, with foliage like a small Rosemary, also claims special mention here. There are a number of quite dwarf yellow-flowered species of which H. lunulatum is one of the choicest, and the Sun Rose usually sent out as H. polifolium is a robust and reliable grower anywhere.

All of the above are hardy enough for most places and, being lime lovers, they will prosper where Heaths might not be so successful. The true Cistuses, good as they are for dry soils and sunny aspects, are no more long-suffering here than the Helianthemums of garden origin. We have places that even they cannot stand without a check should the summer be droughty. But, even so, the Rock Roses are, as a race, reliable enough for the general run of dry gravelly soils and, provided the climate is suitable, very beautiful effects can be produced by massing these shrubs on warm slopes, either alone, or as a backing to groups of Helianthemums.

All the creeping or semi-prostrate Cotoneasters are first-rate for covering sloping ground that does not admit of cultivation, and CC. congesta, microphylla, thymæfolia and adpressa are all particularly happy in such conditions. C. horizontalis, with the prostrate form, is also vastly more pleasing grown thus than it is against a wall, and C. humifusa, most prostrate of all, is ideal for the purpose. Any of the dwarfer among these may be used as a ground covering for other shrubs, or they can be interspersed with their own kind, such as CC. pannosa, Dielsiana, bullata, Francheti and others, with good effect, most of these being able to stand a deal of drought without signs of suffering.

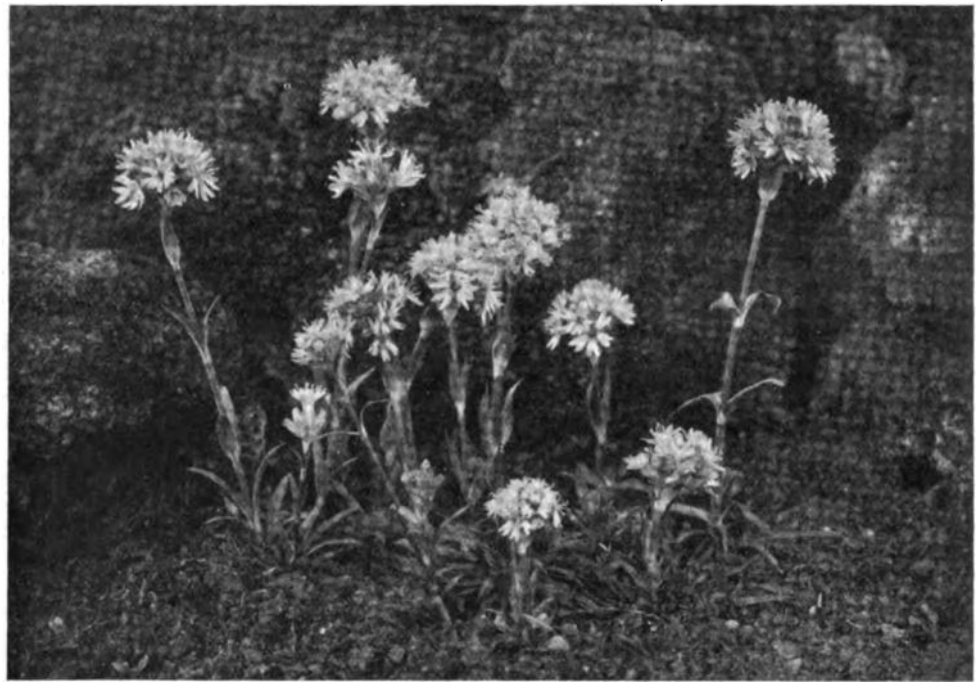
The shrubby Salvias and Lavenders are good dry-soil plants and, as a low-growing flowering shrub, the prostrate Rosemary would be difficult to excel, for its fine dark green is cheerful at all seasons. Santolina Chamæcyparissus must also be mentioned here, and the peculiarly vivid green of a patch of S. viridis is a heartening thing to look upon when most shrubs are shrinking beneath a pitiless sun. The hybrid Colutea media is a trustworthy shrub, for such conditions and we are trying Adenocarpus decorticans in one of our hottest places where it will also get some winter protection.

Artemisia tridentata, the grey-leaved, fragrant Sage Brush of American plains, is quite content with the most sterile of baking soils, and there are a number of other shrubs in this genus, including A. Abrotanum (Southernwood) and its varieties which are eminently suited to our purpose here. The shrubby, or sub-shrubby, Rest-harrows (Ononis), Muehlenbeckias, Convolvulus Cneorum, Burnet Roses, Rosa Wichuraiana, Berberises buxifolia and Hookeri and others, Olearia Haastii, Yuccas and Cassinea fulvida may also be mentioned, in concluding a very incomplete list, as serving to show what a great variety one has to choose from in selecting shrubs for the purpose in view. A. T. J.

THE CAMPIONS

THE Campions belong to the Pink Order (Caryophyllaceæ). There are thirty species spread over the Northern Temperate Regions, mostly in Europe and Asia. There are only a few in America, and those of little value from a garden point of view. Included in the genus Lychnis are several species which have been placed in other genera by various authors. These genera include Agrostemma, Viscaria, Githago and Petrocoptis. The differences, however, are so slight that there is no purpose in keeping them up, and it is more convenient to retain the plants in one genus. The characters of this genus are those of Silene, from which it differs in having five styles and in several other minor points. The Campions have showy flowers, some of which are so brilliant as to give rise to the name Lychnis, which signifies a link or lamp. All the species, including perennials and annuals are of easy culture, thriving in almost any garden soil, but succeeding best in a half-shady position in light rich loam. The perennials may be propagated by division in autumn or spring, or by means of seeds, which as a rule are produced freely. The annuals may be sown in the autumn or spring in the open border where they are to flower. Thinning out the seedlings should be attended to early in order to give them plenty of room to develop.

The various members of the genus are useful for all kinds of gardening. For the wild garden we have one of the easiest-grown species in L. coronaria, commonly known as Agrostemma coronaria. It spreads rapidly by means of self-sown seedlings, and makes striking groups of vivid colour that are very effective in the distance. For the border few dwarf plants are brighter than the German Campion (L. Viscaria) and its fine varieties, while other good border plants are the lovely forms of L. Haageana and L. chalcedonica. Such dainty plants as LL. alpina, Lagascæ and pyrenaica make pretty groups in the rock garden and are useful for growing in pans for display in the alpine-house in spring. The following are all good garden plants:



THE NEAT-GROWING LYCHNIS ALPINA.

L. ALPINA.—The Alpine Campion is a charming little plant which is found wild on the alpine moors and ravines in Cumberland, and in parts of Scotland. It is also spread over the mountain chains of the northern regions, usually found on the highest granitic and limestone rocks near the snow line. It is a tufted plant with rosettes of narrow leaves from which are produced the flower-stems, only 3ins. or 4ins. high. The rose-coloured

Digitized by Google

flowers of the typical plant are produced in dense heads in May and June. It is variable in colour, some forms having pale pink and others almost pure white flowers. There is also a double-flowered form which is very attractive. This plant thrives on a sunny ledge in gritty soil, and is easily raised from seeds sown in spring.

L. CHALCEDONICA (Jerusalem Cross).—There are several varieties of this showy species, including forms with single and double scarlet, and single and double white flowers, and others of intermediate shades of colour. Both the species and varieties have been grown in our gardens for over three hundred years, as they were mentioned by Gerard in 1596. It is a native of Russia, but it is also found now in other parts of Europe, forming bushy plants up to 3ft. or more high with leafy stems bearing bright scarlet flowers in terminal heads from July to September. The type may be increased by division or seeds, but the varieties are best increased by cuttings taken off in the early summer.

L. CORONARIA (syn. Agrostemma coronaria).—The Common Rose Campion is a short-lived perennial, and is remarkable for its thick woolly leaves, which are covered with a silky down so as to look quite white in the distance. There are several forms, including var. alba, a good white; var. oculata, having white flowers with a rose centre; var. atrosanguinea, rich crimson purple; and var. Walkeri. The latter has rose-crimson flowers and is supposed to be a hybrid with L. Flos-jovis, but appeared spontaneously in a garden in Chester, where the two parents were growing. The species is a native of the mountains of Italy and other parts of South Europe, extending to the Caucasus, and has been in cultivation as long as the above species.

L. DIOICA, Red Campion (syn. L. diurna), is a native plant which grows from 1ft. to 2ft. high, and bears purplish rose-coloured flowers from May to September. It is a showy and pretty plant under cultivation, especially the double-flowered form, which can only be increased by division. The single-flowered type is a good wild-garden plant and effective in the hardy fern border. L. Preslii is a glabrous-leaved form of this species of more erect habit.

L. FLOS-CUCULI, Ragged Robin.—Another pretty British plant which is usually found in moist situations on the edges of streams or in marshy ground. It grows about 2ft. high, and bears rosy red coloured flowers having deeply cut petals. Var. alba is a beautiful white form, and there is also a double-flowered kind grown in gardens. In congenial situations the typical plant spreads rapidly, soon forming large colonies.

L. FLOS-JOVIS, Rose Campion, Flower of Jove (syn. Agrostemma Flos-jovis).—A native of Switzerland, this is closely allied to the Common Rose Campion (L. coronaria) in habit and appearance. It grows about 18ins. high and has purple to scarlet flowers in umbellate heads in July.

L. FULGENS.—A handsome plant from Siberia, from whence it was introduced into cultivation in the year 1819. It grows about 1ft. high and bears large flowers of a brilliant vermilion colour during spring and summer. The petals have a ragged appearance, being four cleft, with two large and two small divisions. The stem and leaves are hairy, as in most members of this genus. It thrives in a light rich soil in a half-shady situation.

L. GRANDIFLORA (syn. L. coronata).—This handsome species is a native of China and Japan, and has been in cultivation about 150 years. About 1ft. high, it differs from most other species in having smooth leaves that are ovate in shape and sessile on the stem. The scarlet flowers, 2ins. in diameter, are solitary or in twos or threes, and are produced in the summer and autumn. It is a good perennial, but requires a sheltered, warm position in good soil. In contrast to L. fulgens, of which it is sometimes classed as a variety, the segments of the flower overlap, forming a perfect-shaped bloom with a toothed margin instead of the laciniate one of L. fulgens.

L. HAAGEANA.—Under this name we get a race of beautiful border plants with flowers of various shades of colour. L. Haageana is of hybrid origin and one of the parents must be L. fulgens, as it has the same shaped flowers with similar cut-flower segments. Indispensable for the border, it grows about 1ft. high, with shaggy hairy stems, purplish lanceolate leaves and flowers two or three together during the summer. The flowers range in colour from brilliant scarlet to pure white, and are each about 2ins. across. It is easily grown in the open border, and is a good perennial, easily raised from seeds or increased by division. Probably only one of the numerous forms of this, a plant was exhibited at the Holland House Show in 1913 under the name of L. Arkwrightii. It was stated to be a hybrid between L. Haageana and L. chalcedonica, but shewed little, if any, trace of the latter. It had traces of the purplish leaves of L. Haageana and large flowers.

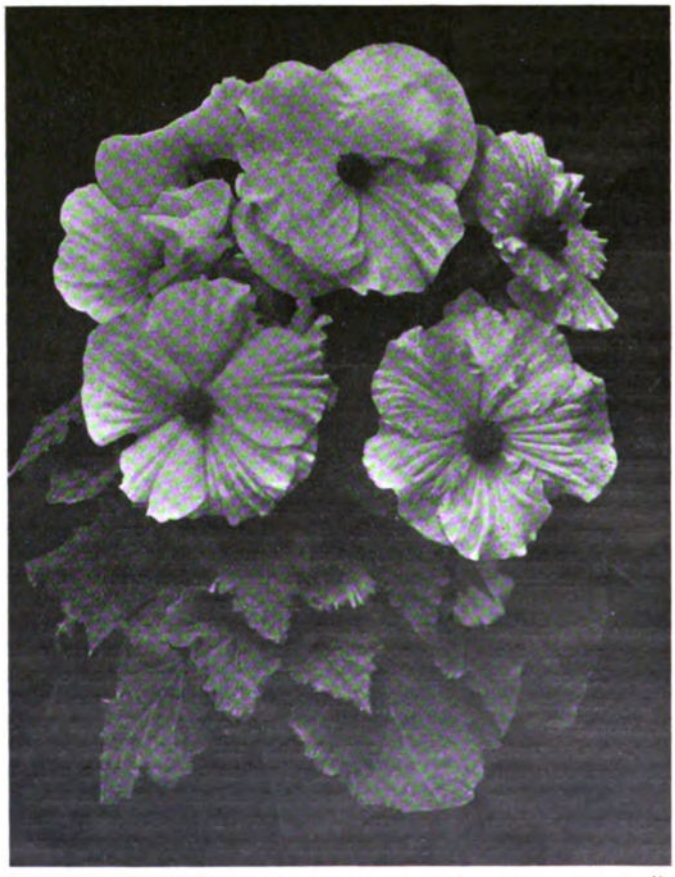
L. LAGASCÆ (syn. Petrocoptis pyrenaica).—An elegant little compact-growing plant for the rock garden, it will thrive on sunny ledges. Only 3ins. high, with freely branching stems and glaucous obovate leaves, it produces during spring and summer bright rose-coloured flowers with white centres in great profusion. A native of the Pyrenees, it is easily raised from seeds sown in spring.

L. PYRENAICA.—Closely allied to the above, of the same growth and habit, but with flesh-coloured flowers, this is probably only a colour variety, although given specific rank by some authorities. It also comes from the Pyrenees.

L. VISCARIA, German Catchfly or Campion.—A valuable border or rock plant of low tufted habit with numerous dark green, narrow leaves and smooth clammy stems 1ft. high. The rosy-coloured flowers are produced in close heads during the summer months. There are several very desirable varieties of this pretty plant, the double-flowered form and one with deep red flowers being especially so. It is a native of this country, and its distribution extends through Europe to Siberia. W. I.

THE CULTURE OF THE BEGONIA.—II

THIS brings us to the method of starting the tubers. The time of starting depends largely upon the date when flowering is required or the temperature that is available. Great heat is neither necessary nor desirable; the more naturally they start, the better the result. Where a long succession of flowering plants is the aim, it is best to start two or three successive batches at intervals, and a note should be made to do this in such a way that the plants which were the first to go to rest the previous year should be the first to be started in the following spring, so that all tubers may enjoy an equal resting period. Whatever batch one starts, it is best to give a brisk warmth at first, about the same as that recommended for seedlings, and cool it down later when the growth is well started. If the heat is not sufficiently brisk at the commencement, one finds that the tubers are very irregular in starting. Shallow wooden seed trays are the best receptacles for the tubers, which should be embedded in the compost just level with the surface but without covering the tops.



Copyright, Sutton & Sons, Reading.

BEGONIA QUEEN OF WHITES.

The favourite compost for starting is almost pure leaf-mould, kept evenly moist. Daily overhead sprinklings will do much towards hastening the starting of the dormant tubers, although there are two points on which care should be taken in connexion with this. One should always use the water tepid, not drawn fresh from the main nor dipped direct from large store tanks; and water should not be allowed to collect in the concave hollow which almost invariably exists on the top of the tubers, as this may start the process of decay. Once the plants are well started and forming leaves, the sooner tubers are transferred to single pots the better. Root production runs

Digitized by Google

considerably ahead of top growth and, if one waits too long, damage is inevitable in separating the tangled roots. The best compost for potting consists of two parts fibrous loam to half a part each of rotted manure and leaf-mould. Do not use too large pots for the first potting, about 1in. larger all round than the tuber itself is sufficient at first; then, when these smaller pots are filled, give a shift.

Similar growing conditions to those detailed under seedlings should be provided until the plants begin to form their buds, when more air should be admitted and a considerably drier atmosphere maintained. Careful management at this time makes all the difference, and it is only by judicious shading, careful watering and ventilation that the best results are ensured. One ought not to shade too heavily; a light screening during the hottest hours of the day is all that is required. Dense shading results in drawn plants, with thin, flabby foliage and poor flowers. Keep the temperature down to a reasonable limit, as an excess in this direction considerably shortens the flowering season and produces flowers which are poor in colour and wanting in substance. Watering is a tricky matter to the unskilled, and considerable trouble with that most annoying phase—bud-dropping—is likely to be experienced.

The ideal is to have the soil always damp, but never too wet nor too dry, and the nearer this can be reached, the less the plants will drop their buds when just upon the point of expanding. Keep the under-stage ventilators open both night and day; space the plants well out so that there is no crowding; and, when water is required, apply enough thoroughly to soak the soil, then no more until the surface begins to dry slightly. Light-coloured Begonias are considerably worse behaved in the matter of bud-dropping than those with darker flowers, and therefore greater care should be exercised when watering light-coloured varieties.

The question of feeding the plants is an all-important one. Never feed until the flowering pots are well filled with roots, then use as wide a variety of stimulants as possible, but always with one proviso—let them, whatever their nature, be weak. Liquid animal manure, patent fertilisers, chemicals, soot—each and all of these have their value and should be used after previously watering the soil with plain water.

After carrying the plants through their flowering season, we come to another very vital phase of their future well-being, the slow, gradual ripening off and putting to rest for the winter. Increase the amount of air, lower the temperature and, as the tops become yellower and yellower, correspondingly reduce the water supplied to the roots so that the sap is gradually driven back into the tubers themselves and the stem falls off, a sure indication that perfect ripeness has been attained. But it is possible to hasten this by too suddenly cutting down the water, and, although the stems may fall, such tubers are the ones that fail to start freely in spring or become a hard, dried-up mass during winter. After the stems have parted from the tubers, give them a few days more for the outer skin to harden, then store.

One cannot propagate named varieties, which are usually double, true to type by means of seeds, and, in their case, cuttings must be used to increase one's stock. These cuttings are easier to root than one might suppose in view of the succulent nature of the stems, the main point being great caution in the application of water until a callus has formed and begun to form a few roots. The best time for this work is as early in the season as sufficiently long shoots can be obtained. The cuttings are then far less liable to decay than when taken off later in the summer. The best cuttings are formed of shoots 2ins. or 3ins. long, snapped rather than cut off, so as to avoid bruising the succulent stems. Lay these on the greenhouse shelf (but out of the sun) for a few hours partially to dry the base, then insert in very sandy soil and place under a bell glass in a temperature of between 60° and 70°. Do not press down the soil too hard, keep the atmosphere moist and water very sparingly. When roots begin to form—which can be told by renewed growth—the cuttings should be gradually hardened off and accustomed to the air of the house in which they were rooted, and, shortly after this, transferred to single pots and grown on steadily and rapidly to obtain as fine tubers as possible before winter.

W. CANNING-WRIGHT.

(To be continued.)

PREPARED CYNTHELLA HYACINTHS

I HAVE been told by trade growers in Holland that my advocacy of Cynthella or, as many still know them, miniature Hyacinths was an important contribution to their popularity. The old men of the Hyacinth world were aghast at the very idea of anyone liking these "hobbledehoys" better than the properly finished article. Some looked on the suggestion almost in the same spirit that greeted the introduction of Arkwright's new machinery among the weavers; it would spoil to some extent the trade *par excellence* of Holland—and then the deluge! The result has falsified their fears. Every English bulb-list contains an offer of Cynthella Hyacinths, and very often gives a picture of some in low pans or small pots to shew would-be purchasers that the letterpress that accompanied it was no high-falutin description. Cynthella Hyacinths have come to stay. Readers may remember a picture of pans of Hyacinths in full bloom at Haarlem on, I think, December 23, 1922, which appeared last February in THE GARDEN. It was an example of what "prepared" Cynthellas are capable of doing under proper treatment.

CYNTHELLA HYACINTHS AND OTHER BULBS AT A HAARLEM SHOW IN DECEMBER, 1922.

I doubt if we shall ever be able to "prepare" Hyacinths in Great Britain, for, akin to what Mrs. Glasse said of the hare in her famous book of cookery, we must first grow them, and it is almost certain that this can never be done successfully. In fact, I rather think that the South of France has been laid under contribution for their last season's growing and preparing. Something has gone wrong with the well known old Roman Hyacinths of late, and the best bulbs are very expensive. Prepared Cynthellas may be relied upon to take their place from the middle of December onwards. Anyone with a warm greenhouse that never exceeds 55° can very easily have them in full flower at or just before Christmas provided the bulbs are obtained and potted in good time.

My own were started on August 17 and grown in a darkened cold frame in the usual way until they had made good roots and about 1½ins. of top growth, when they were transferred on October 26 to a temperate greenhouse of which some three hundred Nerines were the only other occupants. Naturally, the Hyacinths were not forced in any way. But when December came, a trifle more heat and rather less air was given, with the result that I had a number in flower for Christmas. It would have been an easy matter to have had a big display on December 20, hence I can safely recommend these "prepared" Cynthellas as good substitutes to readers who like the old Roman type. Better, let me say, that I found the Dill seeds which grocers sold as Caraways in war time.

The three varieties which I have grown are L'Innocence, Schotel (pale blue) and Grand Vainqueur (pink). The last named has more slender-looking spikes than the other two. L'Innocence comes into bloom the first of the three. All three provide attractive little spikes of bloom for small vases.

JOSEPH JACOB.

FORTHCOMING EVENT.

January 15.—Royal Horticultural Society's Fortnightly Meeting.

A HANDBOOK OF CONIFERÆ

REVIEWED BY PROFESSOR A. HENRY.

THE cultivation of conifers in this country is on a grand scale, both for ornament and for production of timber. The number of species that has been introduced into our gardens, parks and forests from foreign lands is immense and their discrimination is not an easy matter. In addition to the typical wild forms, which are always reproduced by seed, there are numerous sports which have arisen from solitary buds or stray seedlings; and these are usually propagated by grafts or cuttings. The occurrence of sports and hybrids increases the number of distinct sorts of conifers in cultivation to well over a thousand, and much study is required to guide the student through the maze. The most recent treatises of a general nature in English are Clinton Baker's "Illustrations of Conifers," in which plates reproduced from photographs of accurately named specimens clearly elucidate the form of branch and leaf and cone that is characteristic of each of the introduced species; and Elwes and Henry's "Trees of Great Britain," which contains full accounts of the conifers in cultivation. Both these works were issued in limited editions, and are now expensive and hard to procure. Veitch's "Manual," which for a long time was the standard textbook on conifers, is now out of date, and indeed was never really satisfactory, as it contained no keys for the identification of closely allied species. To those who know German, Beissner's "Nadelholzkunde," the second edition of which appeared in 1909, is replete with information on sports and peculiar forms in particular; but otherwise it is similar in character to Veitch's "Manual." Tarouca and Schneider's "Unsere Freiland Nadelhölzer," of which a new edition was published this year, is a fine book, with over 300 illustrations, depicting admirably the habit and botanical characters of numerous species.

Photo, Sir John Stirling Maxwell, Bart.

SCOTS PINE (PINUS SYLVESTRIS) AT ORTON, SCOTLAND.

The frontispiece to "A Handbook of Coniferæ."

This volume* fills a gap in the English literature on conifers. The authors have been aided in their researches not only by their colleagues at Kew Gardens and the Kensington Natural History Museum, but also by the eminent French authorities, MM. Pardé and Hickel, who sent them many interesting specimens from the National Arboretum at Les Barres and other French gardens and nurseries. Mr. Dallimore's long experience at Kew, both in the Arboretum and as an Assistant in the Forestry Museum, enables him to write with knowledge concerning the uses and qualities of coniferous timbers, and gives authority to the notes on cultivation, fungoid diseases and insect attacks, which he has interspersed throughout the volume. Mr. Jackson, who has catalogued the fine collections of trees at Syon, Woburn and Westonbirt, has seen most of the species and varieties in the living state—an indispensable qualification for the botanist whose task lies in their determination and description. I congratulate the two authors on the result of their labours, which have been crowned by the Royal Horticultural Society's award to them of a prize and the Veitch Memorial Medal.

The handbook is carefully compiled and can be relied on for accuracy within the limits imposed by the authors, who state that they write more from the point of view of the forester and the gardener than that of the botanist. The result is a practical work. The genera and species are alphabetically arranged under the two families, Taxaceæ and Pinaceæ, into which the conifers are divided. This renders the book easier to consult than if the species had been grouped according to their natural affinities; but one wonders why a single alphabetical series was not adopted as a further step in simplification. The handbook differs from most of the treatises hitherto published, in including all the known species of living conifers, which are estimated at 380 in number, grouped into forty-four genera. The non-introduced species are very briefly dealt with, but their inclusion will render the book more acceptable to residents in the warmer regions of the Dominions and Colonies, where species unsuitable for our climate are met with.

The book is well printed and finely illustrated, a most useful feature being the 170 excellent drawings by Miss G. Lister, which faithfully portray the branches, cones and seeds of the most important species. In addition there are thirty-one plates depicting individual trees and forest scenes. Those of the conifers of Western North America, reproduced from photographs taken by Mr. F. R. S. Balfour, are of great interest, especially that of Picea Breweriana, the rarest tree in the Pacific Coast region, with wonderful pendent branches, and that of the grove of Abies amabilis in an alpine meadow on Mount Rainier. Such scenes remind us that earthly paradises still exist. That we can grow splendid forests of timber within our own shores is proved by the fine photographs of Scottish plantations of Larch, Common Pine and Sitka Spruce. These were taken by Sir John Stirling Maxwell during war time when the best of our timber was felled. The plantation of Sitka Spruce on the hills at Drumlanrig, however, remains, as it was then only eighteen years old, a fact almost incredible when one looks at the astonishing size of the individual trees, well brought out by the figure of the stalwart forester in their midst.

The authors have maintained throughout the volume a sane system of nomenclature. The trees appear under well known and long established appellations; and the plain man is not bothered with the pedantic names which every now and again are resuscitated from obscure publications, on the plea of priority, by Continental and American botanists. We are also spared, because printing is dear and time is valuable, the long lists of useless synonyms and references to forgotten works,

* "A Handbook of Coniferæ, including Ginkgoaceæ," by W. Dallimore and A. Bruce Jackson. Pages, 570. Plates, 31. Figures, 120. London: Edward Arnold and Co., 1923. Price, 42s. net.

which usually head the descriptions of species. Such information can be readily found elsewhere when required by specialists.

For the ready identification of species, artificial keys are essential, as without their aid it is almost impossible to match an uncommon species with its description. Such keys should enable a tree to be identified on branch, bud and leaf characters only, as cones are often unavailable, on account of the season or of the youth of the specimen under examination. The artificial keys provided by Mr. Jackson will prove, as a rule, workable; but in some cases may be of little use, as in the genus Larix, where the characters of the cones are invoked to aid in the difficult task of discrimination; while for the genus Taxus no key is furnished. The Key to the Genera on page 14 could also be improved. Indeed, the whole of the introductory matter, pages 1 to 17, is scanty in its treatment of matters like seedlings, buds, foliage, wood, etc.; while no information is given about seeds, which are an important article of trade. The plan of the work may, possibly, justify such omissions, but references could have been given to the best accessible authority on each subject.

The writer differs from the authors in regard to some disputable points, such as the origin of Larix pendula, page 296, which is undoubtedly a hybrid, but this is not the place to start a discussion. One may, however, note that L. Mastersiana cannot be separated from L. Potanini; in fact, the Larch of Western China constitutes one species, somewhat variable in the size of the cones.

In conclusion, I have no hesitation in recommending this book to all lovers of conifers. It will prove a reliable guide to foresters, gardeners and landowners.

CORRESPONDENCE

THE TREE POPPY OF CALIFORNIA.

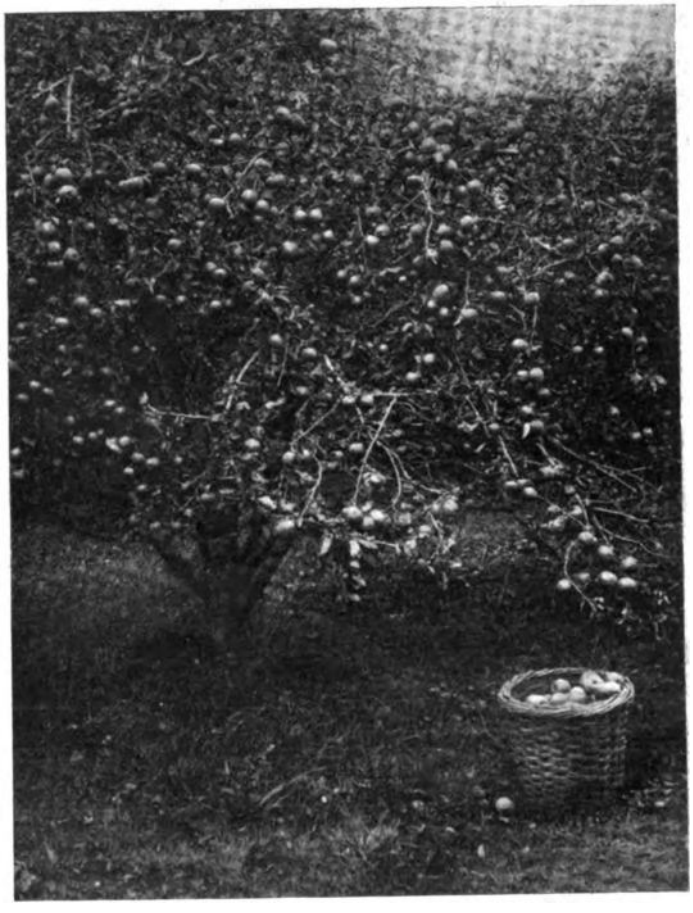
DENDROMECON RIGIDUM is a remarkably beautiful shrub, and although it has been in cultivation for more than a generation, is still rare. This may be attributed to the fact that it is rather tender, but it is not more so than many much commoner plants. Indeed, it is probable that D. rigidum might be grown to perfection in any of our westerly counties, either against a wall or in the open, and it is apparently hardy at Kew, save under extremely severe conditions. There is no doubt but that its life might often be more prolonged were it grown among rocks, or in a stony, free soil, since in such circumstances a very light covering over the base will preserve the root from injury and enable the plant to throw up a fresh crop of branches in spring after the manner of Romneya Coulteri. That, at any rate, is how it is treated here (and we expect our Dendromecons to stand anything in the region of 20° of frost) and it is in a root-run of this kind that it flourishes on the rocky hills of California. D. rigidum is a most graceful shrub, sending up willow-like wands to a height of 6ft. to 8ft. These are furnished with lanceolate, grey-green leaves and, branching freely, they bear at their tips golden-yellow, orange-centred, poppy-like flowers nearly 3ins. across. These open almost flat, are fragrant and last for a week or more. Though the normal flowering season is early summer, the Tree Poppy is seldom out of bloom, and it is this habit of putting out continuous fresh growth that is so liable to lead to injury by frost. The soil, as suggested, should be on the poor side and the situation sunny, a south-westerly aspect probably being the most desirable. In propagation we have have had more success with short, firm laterals taken in spring than with summer shoots.—A. T. J., *North Wales.*

SENECIO ROTUNDIFOLIUS.

DOUBT is expressed by "A. T. J." about the native country of this fine Groundsel (page 678). It is a New Zealander, from the South Island, which ought to ensure its hardiness in all but the colder districts of Great Britain. Cheeseman, whose recent death all good botanists much deplore, describes it as a stout branching shrub or small tree, 6ft. to 30ft. high, growing from sea-level to 3,500ft. We have only small plants here as yet in the open, but these have not flinched under 9° of frost. The flower-heads are without rays, so the bloom is not nearly so handsome as that of Senecio Huntii from the Chatham Islands, which grows to a height of 20ft. and makes a fine display when decked with large panicles of yellow flowers like those of S. Greyi. Its foliage in winter is very beautiful.—HERBERT MAXWELL, *Monreith.*

ABOUT APPLE PRUNING

I AM sending to THE GARDEN a picture that I hope may be of interest. It is a photograph I took, late this autumn in my garden, of an old bush Apple tree of Allington Pippin laden with fruit, and it shews clearly the heavy crop the tree was bearing. Nearly four bushels of nice clean Apples of good size and colour I gathered from this old tree this autumn!—not a bad crop from one tree and in a year, too, when Apples are not plentiful. All those who saw the tree "weighing down" with fruit this autumn were amazed at the sight of so large a crop on the tree. Now, it is of interest to note that very little attention indeed has ever been given to the tree, and yet almost every year it bears this wonderful crop of fruit. No, it has hardly ever been pruned or manured or helped in any way. Weeds, brambles and tough grass grow thickly under the tree, for the soil has not been touched for years! How is it, then, it does so well? The soil of course, is very deep and good, but I say this: "Leave the trees a little more to Nature and they will do well." I never did believe very much in hard pruning: cutting and slashing the trees about as fast as they grow! This seems to me quite the wrong way to go to work. It certainly is with orchard trees. The only pruning I care to do is to keep the middle of the tree fairly open and cut away the boughs and shoots that rub against others and, of course, cut all dead wood away. Sometimes I shorten long shoots a little here and there, principally to keep the tree a nice shape. I grow a good many trees in my orchard—about 350—and many excellent varieties, and large quantities of fine Apples I gather from my trees each year; I have Apples nearly all the year round. Just to mention a few, I have a long row of each of these: Cox's Orange Pippin, Blenheim Orange, Ribstons, Worcester Pearmain, Lane's Prince Albert, Bramley's Seedling, Sturmer Pippin, etc. The trees are about twenty years old, and nearly every tree, let me say, is a perfect half-standard, but I do little pruning. Although I leave my trees very much alone, I always have some very beautiful fruits in my orchard each season, and I should like just to add here that for my brilliant red Apples Worcester Pearmain I was given second prize at the first great exhibition of fruit held at the Crystal Palace a year or so ago.—SIDNEY M. HALLOWES, *New Milton, Hants.*



A LADEN TREE OF APPLE ALLINGTON PIPPIN.

CHRISTMAS BLOSSOM.

FOR several years now you have published a list of the flowers in bloom on Christmas Day in two gardens at West Porlock, that of Mr. G. W. W. Blathwayt and my own. Christmas, 1922, established a record with 250 species in flower after an exceptionally mild spell. As we experienced 9° of frost on two nights in November last year and a few degrees on several other nights, we did not expect to be able to record more than 100 kinds this Christmas, but find the actual score is 144. The list is as follows: Abelia floribunda, Abutilon megapotamicum, A. Canary Bird and a red variety, Acacia falcata, Anchusa myosotidiflora, Anemone coronaria, Antirrhinum majus, A. semperviren, Aster Amellus, Arabis

Tinus, Viola cornuta, V. odorata (single and double), V. tricolor, Valerian (Centranthus), Verbena radicans, V. Chamædrys, V. (bedding variety), Veronica Cataractæ, V. Cookiana, V. angustifolia, V. speciosa and V. hybrids.—N. G. HADDEN, *West Porlock, Somerset.*

ABOUT FREESIAS.

IN reply to Mr. Joseph Jacob's letter (THE GARDEN, December 22, 1923, page 665), *re* Freesia "duds." I gave my opinion about this trouble and it was rather scoffed at two or three years ago. However, I have never been troubled with duds and I overcome the difficulty of a sunless summer quite easily. The whole thing is a matter of thorough ripening, and, chiefly, warmth. I gave Mr. Jacob instructions as to what to do and I think he is giving readers the impression that *he* discovered the cure. I do not "heat the corms," merely ripen off thoroughly in the pots or beds. I keep them, after harvesting, in a warm, dry atmosphere. Of course, if the corms do not get sufficient moisture after potting, there is a great likelihood of their becoming duds, but the trouble is easily overcome by a little careful cultivation in either case.—G. H. DALRYMPLE, *Bartley, Southampton.*

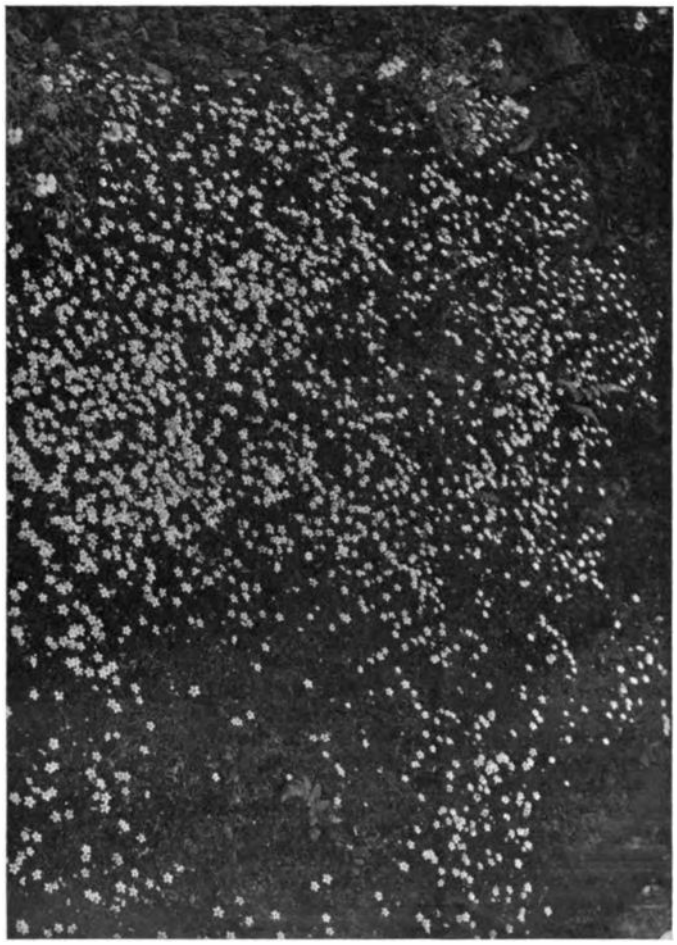
FREESIAS SEEDING OUTDOORS.

A CORRESPONDENT in THE GARDEN for December 22 (page 665), asks if Freesia seeds ever have been gathered in any part of the British Isles. Here, in Maidencombe, Devon, Freesias in the open have flowered and seeded regularly every year for the past twenty years and more. From a dozen seeds first planted there are now borders and patches of them. The colour and markings vary, and the stems are stiff and carry many blooms, which are stronger in scent than pots of Freesias grown in a cold greenhouse. They come into bloom about the same time, according to weather.—PENWARRE, *Maidencombe, Teignmouth.*

A HOLLY PUZZLE.

HAVING become possessed of some very fine Golden Queen Holly, I shared it with two friends. In each case part of it was placed in water in vases or epergnes, the remainder being utilised for decorative purposes without water. In both instances the twigs which were placed in water began in a few days to shed their leaves, and in ten days had shed about half of them, while the pieces which were not placed in water in the same room had not shed a single leaf. A lady friend of mine tells me that she has had a similar experience with Common Ling. I wonder whether any reader of THE GARDEN can give a scientific reason for this strange behaviour, which is the direct antithesis of the usual order of things.—CALEDONIA.

["Caledonia" is, no doubt, well aware that when newly planted evergreens shed their leaves the symptom is regarded as favourable. When the foliage shrivels on the tree, however, the planter's hopes fall. The casting of the foliage indicates that the sap is circulating and the tree making a serious attempt to accommodate itself to the new conditions. Surely the behaviour of the cut Holly sprays is, in the light of this experience, exactly what one might expect.—ED.]



ARENARIA BALEARICA ON A SHADY DRY WALL.

THE BALEARIC SANDWORT.

I HAVE often suffered through taking too readily to my heart plants recommended to me by friends and I should like, with your permission, to point out the importance of keeping Arenaria balearica, so often—and rightly—recommended for dry walls and semi-wild paths, away from choice plants in the rock garden. The late Reginald Farrer wrote that ". . . It should never be admitted within seeding distance of anything choice or precious, otherwise the gardener's time is taken up for ever more with clearing the latter anew every day from the octopus-like attentions of the Arenaria." It is a true indictment, but it is equally true, as he says, that "for wild rocks, walks, walls and cliffs there is nothing more . . . beautiful." It may be well to point out that as a carpeter for bulbous plants such as Muscari, Scillas, Chionodoxas, etc., this species is unexceptionable, always provided that no really choice alpines are within range of broken-off fragments or self-sown seeds.—G. HARVEY.

THE FIFTY BEST ALPINES.

I MUST apologise for the excessive delay in accepting Mr. Stewart Wacher's invitation (THE GARDEN, November 24, 1923) to correspond with special reference to certain plants. Perhaps I should commence by saying I am a new-comer to the delights of rock gardening, and that my list was primarily intended to provoke discussion, thus furthering my education and providing selections for future operations. And now to discuss the plants he mentions. Aquilegia alpina, seen while in Switzerland this year, was purchased and is apparently very happy. Whether it will flower remains to be seen. Treatment given is rough open scree, planted as received with extra sand added. Cyananthus lobatus grew readily and flowered, but so late in the year that the flowers did not get fully developed. I suspect the plant likes a lot of hot sun, and this summer was very scanty in that respect and far too late to be worth mentioning. Treatment is scree with more loam and a position which gives shelter from early morning sun and a chance to sprawl down the side of a ledge. Daphne rupestris is quite alive, though not yet big enough to flower. Evidently grafted on to another Daphne and, alas! rather the worse for cats, which have knocked off a couple of shoots. These appear to be terribly brittle. I am most anxious to see D. rupestris in its native haunts, and hope to achieve this next summer. Ranunculus glacialis, collected in the Oberland this year, is still alive but a great worry, as slugs seem to worship it.

Digitized by Google

Hope to see it flower safely, as it stood the journey well—treatment, granite chips, loam and sand (no lime) and a choice spot on scree. I fear the difficulty will be providing enough water in the spring. Viola Bertoloni.—What I have of this grows well on a rock bank facing west with limited amount of sun, in very sandy loam with touches of leaf-mould and peat. From this you will see I cannot render much assistance, which, indeed, is not surprising seeing I am such a novice. The lists contributed have helped me considerably, and I should like to thank Mr. Wacher for his. Many kinds he mentions I have not got, notably Dianthus gallicus, Polemonium carneum, Saxifraga Aizoon baldensis and Wahlenbergia vinceflora. The first two are quite unknown quantities, the third a prospective purchase, while the last is surely rather too tall growing to be welcome in association with the usual rock plants.—PURLEY.

RAISING GREENHOUSE ANNUALS.

TO many people there is little distinction to be drawn between these and what are known as half hardy annuals. If full success is to be attained with such kinds as Celosias, Sensitive Plants, etc., the difference must be recognised and observed. Early sowing and a fair amount of heat are the chief points of importance where greenhouse annuals are concerned, the more important of these twain being the early date of sowing. In almost every case, a longer period of growth is necessary before the flowering stage is reached than with the "half hardies," and sowing is best carried out early in the year, so that the plants may be gradually built up into fine specimens rather than "rushed" into bloom under the greater stimulus of extra sun heat and longer hours of daylight. Prick off at an early stage of their growth—preferably singly into small pots—and keep the atmosphere moist and the ventilators closed for a few days after the operation. Another important item is to see that the young plants never become potbound until the "final" size pots are reached and that free supplies of liquid manure are then given to the roots.—CROYDON.

THE HARDINESS OF THE MONTPELIER BROOM.

THERE seems to be such a wide difference of opinion as to the hardiness of this beautiful species that one wonders whether this may be accounted for by the possible existence of several forms of the species, some being more robust than others. We know that in a state of nature Cytisus monspessulanus (candicans) has an unusually wide range on both sides of the Mediterranean, and Mr. Bean ("Trees and Shrubs") tells us that it has been naturalised in N. India and introduced to this country from there. The same authority states that this Broom succumbs to 15° to 20° of frost at Kew. How, then, does it manage to endure that and more with us, without any worse injury than getting its foliage slightly "singed" at the extremities, while even that amount of damage is rare? Indeed, several groups of this Broom growing here came unharmed through a winter ordeal (such as we had in early 1917), which browned the Common Gorse. One can only assume in the face of these facts that there are tender and hardy forms of this species, as I have suggested.—A. T. JOHNSON, *Talycafn, N. Wales.*

IRIS UNGUICULARIS IN VICTORIA, B.C.

HAVING read several articles in THE GARDEN commenting upon the early-flowering of Iris unguicularis (stylosa), I think, perhaps, the following may be of interest to your readers. A year ago I imported half a dozen plants from Messrs. Bees, Limited, and planted them at the foot of a 5ft. dry wall, with a southern exposure. The soil consisted for the most part of gravel, with leaf-mould added. The first bloom opened on November 30 last and I have had three more open since, up to the time of writing (December 8). Is this unusually early? We find the climate here really excellent for growing alpines of all sorts.—NORMAN W. F. RANT, *Victoria, British Columbia.*

[It is not at all unusual for the first blooms of Iris unguicularis to open in November in Britain. —ED.]

LOOK OUT FOR SIGNALS!

WE hear of and see so many failures in fruit-growing which would not happen if the trees and plants were treated in a rational manner. Although our good old establishments with their skilled gardeners are, unfortunately, rapidly disappearing, there are perhaps more amateurs and owners of small gardens than ever. One of the mistortunes, however, is that these small owners are apt to depend too much on men who call themselves gardeners, and who may be worthy of that honourable name as far as growing some kinds of vegetables and keeping a lawn and walks neat go, but who are at the same time totally devoid of skill in the culture of fruits, though they profess, and probably think, that they know all about it.

I should like the owners of such gardens, if they cannot afford to keep a competent man, to try to master a few elements of horticulture, so that they may be able to take the direction of the work into their own hands and also participate in it if they can spare the time.

I do not envy the person who can find no enjoyment in gardening; there is such an amount of pleasurable interest to be found in it that I cannot conceive attainable in any other way. Heaping up money is very alluring to many, but we have proof in some of the American millionaires that money alone does not always bring happiness. Gardening, supposing the necessities of life are not wanting, may always do so.

When one gets to love his plants and understand their little ways of making their wants known, it is astonishing how they respond to what appear to be small attentions. It hurts me almost as much to see a plant suffer as to witness sickness in animal life. If a plant under my care seems not to be thriving, it almost says "Come and help me," and I am not satisfied till I find out its wants.

It is not only the members of the Mimosa family and Fly-traps that are sensitive. Even the common culinary Pea gave me a surprise a year or two since. Some rows were unavoidably allowed to grow without sticks longer than they should have done. I placed some small twigs against them at eleven o'clock one morning and at three o'clock the same day I called the attention of a lady and gentleman to them. Three of the tendrils had already clasped round the sticks and scores of others were reaching out towards them, some of them having actually bent back from their former position for the purpose. It is a mystery how the tendrils gained their information.

Then in the case of plants flagging for want of water or at the approach of night, some of them turn their leaves in such a way as to present the smallest possible amount of surface to radiation, but they are not all so well educated. One hot and bright day I was working in a vinery where the leaves had scarcely attained their full dimensions, when suddenly I noticed they were lowering, the leaf-stalks bending backwards. The border was not dry and the atmosphere felt comfortable excepting for the heat. I was puzzled. But soon a terrific thunderstorm came on. The Vines had evidently received a "wireless." Half-starved plants are not so sensitive, only those which have their wants attended to, and then, in the case of Vines, only in their early stages.

We often see plants flagging in the open air, even Potatoes and Cauliflowers, when we know they are not dry at the root, but this is easily accounted for when there is a sudden change in the atmospheric moisture. The pores in the leaves, which scientists call stomata, are automatic, opening and closing according to the humidity of the air, and if it suddenly turns drier these pores are caught napping and cannot close sufficiently rapidly to prevent moisture escaping from the leaves more quickly than it can be supplied by the roots. We cannot prevent this happening in the open, but we ought to be able to do so with the plants inside our houses. By the way, it is frequently overdone there, as when the plants are syringed and shut up towards the close of the afternoon. It may not hurt some plants much which are grown for their foliage, but I have long since learned to do without it in the case of fruits. You stop transpiration by drenching the plants, which has the effect of checking feeding by the roots, for we know that plant food can only be carried up by means of water and gases, and there is necessarily more water taken up than is wanted for building up the tissues, the surplus being discharged through the stomata, and when you check that upward flow you are starving the plant, although you make its leaves and stems more expansive. But expansion and development are not synonymous terms. The leaves also breathe or respire through these pores, and breathing is as necessary for plants as for animals, but a saturated atmosphere checks it. Again, by blocking the pores you prevent feeding by the leaves and, if we except water, plants feed more by their leaves than by their roots, the principal intake being carbon dioxide (or carbonic acid gas as it is commonly called). In the matter of breathing the animal has the advantage, for if the pores of its skin are rendered useless by dirt or grease, it still has the use of its lungs for inhalation and exhalation. The poor plant has no such convenience, and when its pores are blocked by dirt or water it can neither breathe nor feed. It may be said that the pores are frequently covered by natural dew, but the dew is chiefly on the upper side of the leaf and the pores are principally on the underside. In syringing Vines, for instance, the bulk of the water is given to the underside, where there is said to be thousands of pores to a single leaf. I do not claim to know much about plant physiology, but the little I do know is very interesting and a great help to me. I should like to tempt the amateur to learn a bit about it, and he or she will find it will provide pleasure for what might otherwise be a dull moment.

Many a proprietor when asked why a certain thing is done answers "I do not know, but my gardener says it is right." Then when "my gardener" is asked for a reason, he says: "That is the way it was always done at Bidlington, and Mr. Smith was a very clever man; nobody could touch him with Calceolarias."

WM. TAYLOR.

COLOUR SCHEMES FOR THE ALPINE HOUSE

BELOW are set forth a few pairs of plants which are capable of producing lovely combinations of colour, all of which can be quite as effective in the alpine-house as they would be outside on the rock garden. Generally speaking, three plants each of two varieties selected for a specimen pan would be ample (the size of the pan depending on the habits of growth of the occupants), but in cases where tiny bulbous plants are being used it would be necessary in most instances to use many more to get good results. In selecting "partners," apart from the matter of colour harmony, it must not be forgotten to study the requirements of the plants as regarding composts and other cultural requirements, so that both occupants of the pan may be equally at home.

PRIMULA FARINOSA AND MYOSOTIS RUPICOLA.—This combination presents a very pleasing spectacle in May and June, when, from the dazzling azure blue carpet of the miniature Forget-me-not, only 1in. high, appear from mealy green rosettes of leaves the dainty pink blossoms of the Bird's Eye Primrose. They are borne in clusters at the top of mealy stems usually from 3ins. to 6ins. high. The compact tufts which the Myosotis forms also serve to keep the roots of the Primula cool in summer. A compost of loam and leaf-mould in equal parts with a fair amount of coarse silver sand is quite suitable.

GENTIANA VERNA AND ARENARIA VERNA.—These plants make excellent partners, and there is no doubt that the Arenaria is a great help to the Gentian, providing as it does a close resemblance to the natural turf in which the Vernal Gentian grows in its native habitat. A. verna is a rare Britisher, and it forms a dense emerald green mat of minute grassy growth and bears abundant white flowers, which are large in comparison with the size of the plant. G. verna is too well known to need description. Leaf-mould, lime-stone chips and sand make a "champion" recipe for a compost for both plants. They are in bloom together for the better part of two months, but the beginning of June should find them in their best form.

ASPERULA NITIDA AND ALLIUM CYANEUM.—A well drained gritty limestone mixture and a sunny position suit these plants admirably. The Asperula forms a dark green moss-like carpet and bears numerous dainty pale pink trumpet-shaped flowers that sit close to the foliage. Allium cyaneum should be used rather extravagantly, as the growth it makes is very fine and grassy and about 2ins. high. In June it carries heads of powder blue, gracefully nodding blossoms. It is bulbous and is dormant in winter, but the Asperula is evergreen and always attractive.

POLYGALA CALCAREA AND POTENTILLA AUREA.—Here is a happy combination of colour, and both species are quite at home in a gritty compost containing plenty of lime. The Polygala bears its flowers in short spikes of a deep blue colour, the keel-like centre being rather paler than the wings and being very heavily fringed, greatly resembling, indeed, an "Old Bill" moustache in miniature. The golden yellow flowers of the Potentilla are borne close to the foliage, which is prostrate and which, by the way, takes on pleasing autumnal tints. At the base of each petal is an orange blotch.

PHLOX DOUGLASII AND ALYSSUM TORTUOSUM are two delightful carpeters, both perfectly prostrate and evergreen, and of easy culture in ordinary gritty soil. The Phlox is one of the best of its kind, and forms a dense mat of dark green, narrow leaves on woody branches. Its flowers are almost stemless, of a delicate mauve shade, and are produced in quantity. Alyssum tortuosum seems rather uncommon at present, but it is a handsome plant with silvery grey foliage and small heads of clear yellow flowers on ½in. stems.

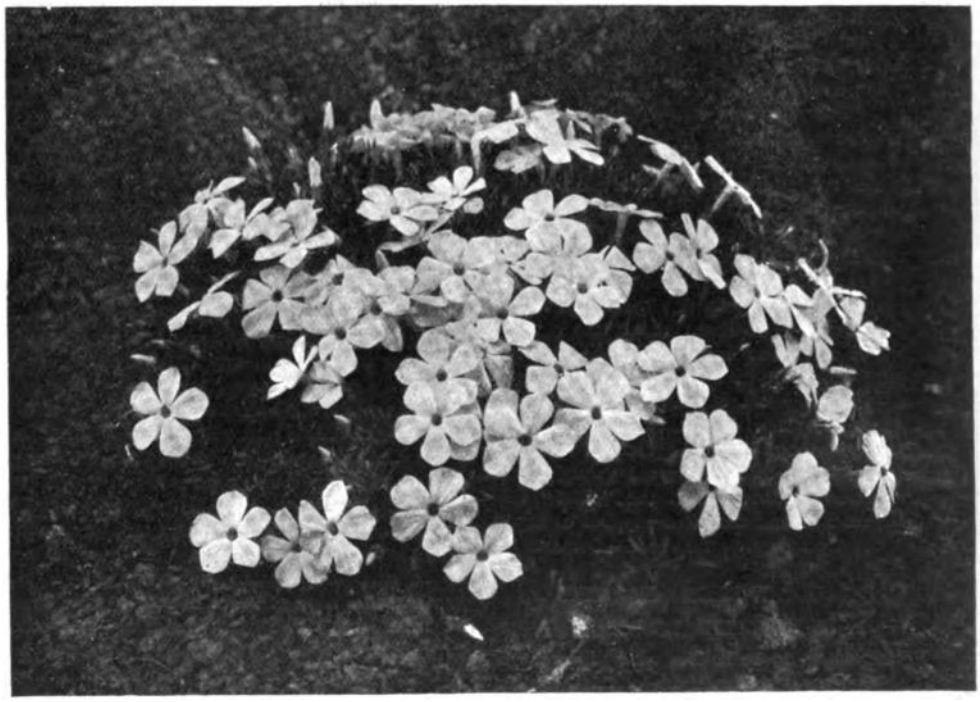
DELPHINIUM NUDICAULE AND ANTHEMIS AIZOON.—I think the only disadvantage with this combination is that the Delphinium is rather short-lived, but it seeds readily and the seeds germinate easily. It reaches a height of from 12ins. to 18ins., and the flowers are of an intense orange scarlet. The Anthemis grows about 3ins. high, with silvery foliage and white daisy-like flowers. Both plants appreciate plenty of sunshine and a fairly dry, well drained compost. The Delphinium is dormant in winter, but the Anthemis retains its foliage and is always good to look upon.

SAXIFRAGA OPPOSITIFOLIA SPLENDENS AND S. O. ALBA.—These two varieties make a fine show about the beginning of March. An open gritty compost suits them, and liberal top-dressings are of great value, as they tend to prevent the centres of the growths turning brown, which otherwise is a common failing with the species. Both varieties make a dense mat and flower profusely. "Splendens" bears large round flowers of purplish rose, but the white-flowered form has smaller flowers, which are rather star-shaped. Give them a cool position in partial shade.

VIOLA BERTOLONI AND SAXIFRAGA AIZOIDES VAR. ATRO-RUBENS.—A well drained compost of leaf-mould, loam and sand in which the leaf-mould should predominate and a cool, half-shady position will serve the two plants in question very well. The Viola has a neat tufted habit, and produces handsome mauve flowers more or less throughout the summer. They harmonise perfectly with the rich mahogany flowers of the Saxifrage. Neither of the plants grows more than 3ins. high under ordinary conditions.

RAOULIA AUSTRALIS AND ASPERULA SUBEROSA.—Here we have a pair that enjoys abundant sunshine and a gritty limestone scree mixture, and which it is advisable to keep fairly dry in winter. The first-named plant is grown for foliage effect only, the flowers being rather insignificant and of a dingy cream colour. The foliage is like silver, and forms a dense carpet which clothes the surface of the soil and does not exceed half an inch in height. The foliage of the Woodruff is a very grey green colour and is covered with silky hairs. It bears its trumpet-shaped flowers in heads, and they are of a most delicate shade of pink.

PRIMULA × PUBESCENS RUBY AND PRIMULA × PUBESCENS ALBA provide a good display of colour in May. Ruby, which has flowers of the colour its name would suggest, makes a splendid contrast to the snow white heads of blossom of pubescens alba, and is marked with a conspicuous white eye. Both plants are easy doers in a cool position if given a mixture of fibrous loam, leaf-mould and a little peat, and both are also deliciously fragrant. Another combination of colour in similar plants would be Primula × pubescens Mrs. Wilson (lilac blue) and P. p. Mrs. Robinson (clear yellow).



ONE OF THE CHOICEST OF DWARF PHLOXES—P. DOUGLASII.

DRABA IMBRICATA (of commerce) AND DRABA PYRENAICA.—These two plants present their blossoms in very early spring. Their foliage may then be likened to a baby Mossy Saxifrage of emerald green colour. D. imbricata bears bright yellow flowers in heads on 2in. or 3in. thread-like stems arising from a low-growing compact hummock of tiny rosettes. D. pyrenaica is very similar in the cushion it forms, but the flowers are almost stemless and are lilac in colour. A warm sunny aspect suits both; so does a limestone scree mixture.

CAMPANULA PULLA AND CAMPANULA PUSILLA ALBA.—These two plants are about the latest to flower in the selection, and both are easy doers in ordinary good sandy soil. The nodding bells of C. pulla are of an intense violet shade, and are about twice the size of the creamy white bells of C. pusilla alba. They flower on slender stems about 3ins. high.

OBITUARY

MR. R. P. BROTHERSTON.

It is with deep regret that we learn of the death of Mr. Robert Pace Brotherston, which took place at the residence of his son-in-law, Mr. M'Naughton, Scone Palace Gardens, on December 21. Mr. Brotherston, who was advanced in years, was for a long period head-gardener to the Earl of Haddington at Tyninghame, Prestonkirk, and only retired a few months ago, when he went to live at Tyninghame, close to the gardens he had tended so long and with such distinction. He was known as one of the best and most accomplished of Scottish gardeners, and his reputation as a practical gardener and a writer on horticultural subjects was world-wide. The gardens at Tyninghame, which are very extensive, were managed with consummate skill, and the hall-mark of efficiency was apparent in every department. Fruit, vegetables and flowers, both outside and under glass, all received their full attention, and the many visitors to Tyninghame were deeply impressed by the ability with which the various departments were managed. During all the years in which Mr. Brotherston was in the service of the Haddington family he enjoyed their full confidence and respect, and he always spoke with deep appreciation of his employers. In Scottish horticultural matters Mr. Brotherston took a full share—in connexion with the Royal Caledonian Horticultural Society and the Scottish Horticultural Society, which are now united, and in all other movements for the advancement of gardening. Besides serving as an office-bearer of these bodies, he also acted as judge at many of the leading shows, and his decisions were always most conscientiously given. To a wider circle Mr. Brotherston was known as an able writer, and he was for many years a valued contributor to THE GARDEN and other journals, and recently a most interesting article from his pen appeared in *Chambers's Journal*. Apart from purely technical articles, which were always of high value, Mr. Brotherston contributed a large number on old horticultural literature, of which he had a deep and varied knowledge. In this he was greatly assisted by the access he had to the library of the noble family he served so faithfully. In private life Mr. Brotherston was very highly esteemed. He was always courteous and ready to help with advice, and all who knew him will deplore his death as that of a true personal friend.

MR. THOMAS D. GRIEVE.

WE regret to have to record the death, on December 25, of Mr. Thomas Douglas Grieve of Redbraes Nurseries, Edinburgh. Mr. Grieve, who was in the prime of life, was an active partner of the firm of Messrs. James Grieve and Sons, nurserymen, and was a well known figure in Edinburgh horticultural circles. He was keenly interested in gardening apart from its purely business aspect, and took an active part in the affairs of the Royal Caledonian Horticultural Society and of the Scottish Horticultural Association, serving on the committees of these leading bodies. Mr. Grieve was a skilful gardener himself, and was much interested in many of the flowers in which his veteran father, Mr. James Grieve, specialised, and maintained the high standard set by that able gardener, who survives his son. Mr. Grieve was much respected personally, and the deepest sympathy is felt for his widow and the other members of the family. The funeral was a private one.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Peas.—For early Peas an open, sunny and warm part of the garden should be chosen, and it is advisable to afford a liberal dressing of manure, when the Peas may be followed by Cauliflowers or Broccoli with excellent results. Flat drills about 6ins. wide are the best, and these ought to be as wide apart as the approximate height of the kind selected. A good hardy variety is Pilot, which grows about 4ft. high, and the rows should be that distance apart. Of similar height is Early Giant, while excellent dwarf varieites are Pioneer and Langley Gem. The seeds should be damped with water or paraffin oil and then dusted with red lead, for it should be borne in mind that at this period of the year germination is somewhat slow and there are many enemies to contend with. Mice should be trapped, and later on slugs will be very destructive to the tender shoots just as they are pushing through the soil. An occasional dusting of soot will help to keep these marauders in check.

Broad Beans.—Those sown in November are through the soil, and promise to yield a good crop. Another sowing of the Longpod type may now be made directly the ground is dry enough to work. Broad Beans enjoy a strong, deep, cool soil, and they may be planted in double lines about 3ft. apart. The seeds should be from 6ins. to 9ins. asunder and planted 3ins. deep.

Early Potatoes.—Where frames and fermenting materials are at hand there is no reason why a small quantity of Potatoes should not be produced early and a few weeks in advance of those grown on a warm border. Make up beds of leaves and long manure about 2ft. larger than the frames, and when the heat begins to recede a 1ft. layer of light rich soil may be placed inside the frames and the Potatoes planted 1ft. apart and 3ins. deep. Select an early dwarf-growing variety, such as May Queen, and the tubers ought to be sprouted.

The Flower Garden.

Crinums.—These are stately bulbous plants that produce their fine spikes of flowers during August and early September. One that calls for special notice is C. Powelli, a rose-coloured hybrid, and its pure white form known as C. P. album. A number of bulbs were planted in an open border ten years ago, and they have never failed to give a good display of bloom. They appreciate a strong loamy soil, and enjoy a liberal quantity of manure near the roots when the borders are dug over during the winter months. The bulbs should be planted 1ft deep, and ought not to be disturbed for a number of years. They may be planted at the present time.

Sweet Peas.—No garden is complete without a few clumps or rows of Sweet Peas, and although a reliable mixed strain has much to commend it, I would advise readers to try at least six named kinds. Last year we tried Royal Scot, Hawlmark Pink, Mrs. Tom Jones, Warrior, Picture and Constance Hinton, and they proved a splendid lot. For early flowers seeds should now be sown in 4in. pots, placing four seeds in each receptacle. The pots should be well drained, and the compost made up of three parts of fibrous loam and one part of leaf-mould, to which add a sprinkling of sharp sand. Arrange the pots in a cool greenhouse, and do not overwater the soil or the seeds will decay. When germination is effected, keep the plants near the roof glass, and directly the seedlings have made three pairs of leaves remove the centre of each plant. Cool treatment should be the rule, so remove the pots to a cold frame when the plants are well through the soil. The sowing of Sweet Peas in pots may be practised until the end of February.

Fruits Under Glass.

Strawberries.—Once the New Year has arrived the work of forcing is more reliable, and with ordinary care and attention few failures ought to be recorded. A brick pit which is heated will do admirably for the first batch, and if a bed of leaves with a little long manure is placed in the pit so much the better. Such a bed will furnish a gentle bottom-heat, which will encourage root action and prevent an attack of red spider. A high temperature is detrimental to the well-being of the plants when they are first removed from their winter quarters, so fire-heat ought only to be used when the temperature is likely to fall below 45° Fahr. When the flower-trusses are seen the temperature may rise 10° or so, and at this stage the plants placed on a shelf where they will receive ample light. Syringe the foliage on bright days with tepid water, but this should be stopped when the flowers are open. At this stage the temperature should be as near 60° as possible, and although plenty of air is needed when the plants are in bloom, it will be necessary to be cautious to prevent cold draughts. A little thinning of the fruits will be needed, six or seven being enough for one plant, and while the fruits are swelling freely the roots may be assisted with a little fertiliser or liquid manure.

Fruit-Houses.—Peaches and Vines not yet started into growth should be kept as cool as possible and such work as cleaning the trees and houses should be completed at an early date.

The Hardy Fruit Garden.

Pruning.—This work should be proceeded with and completed during the next few weeks, the prunings being collected and burnt. Strawberries and Raspberries may be mulched with manure, if the work has not already been done, and any suckers around the latter pulled out.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes.—As the tubers are perfectly hardy and the plants require a long period for their perfect development, planting should be taken in hand as soon as the state of the weather will permit. Select medium-sized tubers and pare off all the eyes except the strongest one. Draw drills with the draw hoe, as for Potatoes, 3ft. apart and plant the tubers 15ins. apart in the drill, cover in with soil, using the feet for this purpose.

Parsnips.—The remainder of the crop may now be lifted and pitted in the open; the pit may be excavated a certain depth to keep the roots moist. If this is done, the space the crop occupied may be manured and dug in preparation for the succeeding crop.

Rhubarb may be obtained for the table some time before the normal period, either by covering a portion of the crop with loose litter or placing over the stools seakale covers or collars made either of earthenware or compressed paper. Early Albert is the variety to grow for early work.

Leeks.—Where Leeks are required for the autumn shows, seed of a high-class variety, such as Dobbie's International Prize, should be sown now in gentle heat to be potted up singly in due course. If subjected to strong heat Leeks are apt to run to seed.

Fruits Under Glass.

Early Peaches.—As soon as the trees open their flowers, either of two methods (wet or dry) may be adopted to facilitate the process of pollination. The trees may either be sharply tapped about noon to disperse the pollen or the trees sprayed with tepid water, using a very fine spray.

Early Vines.—As soon as these have made about 1in. of growth the operation of disbudding should be taken in hand. In the case of young Vines they should be so disbudded that the laterals will be placed at about 18ins. apart on either side of the rod. It is very apparent that many cultivators leave the laterals too close to each other, with the result that the bunches of fruit (and the berries also) are comparatively small, and even the aggregate weight of those second or third rate fruits in a house is less, relatively, than where a more liberal policy is pursued, and where fewer but superior bunches of fruit are produced. In the case of established Vines the distances have been fixed, and if the previous year's laterals were cut back to two buds it will be the case of retaining the more vigorous or the better-placed bud of the two. Close attention should be paid to ventilation, especially in fickle weather, as a sudden burst of sunshine soon runs up the temperature in a closed house, and cloud soon lowers it when ventilation is on. Added to this is the fact that young tender growths are much more susceptible to heat and cold than those in a more advanced stage of development.

The Flower Garden.

East Lothian Stocks.—These deservedly popular flowers may be treated as annuals or biennials. If the whole or any part of them are to be treated

Digitized by Google

as annuals, the seed should be sown as soon as convenient in a temperature ranging from 50° to 55°, or even a little higher. As damping is the young Stocks chief enemy, the seed should be sown rather thinly and in a fairly sandy compost.

Salvias patens and Pride of Zurich.—These two beautiful Salvias, although perennials, may be flowered the first season if sown sufficiently early. If sown now in a temperature of 60° and potted on in due course they will be fit for planting out early in June.

Seedling Pansies.—Seedlings resulting from an autumn sowing should now be pricked off into boxes in greenhouse temperature to be ready for planting out at the beginning of April.

The Shrubbery.

Planting.—November proved such a wintry month that planting was, in many districts, quite out of the question, and as December is not a very suitable month for planting operations, there are doubtless many arrears to overtake. If weather permits, this work may now be taken in hand. If purchases have yet to be made, one's aim in selecting should be to spread the maximum beauty of the various plants over as great a proportion of the year as possible, specially remembering the duller half, *i.e.*, late autumn, winter and early spring. This suggests, among others, the following: Berberises Thunbergii and Wilsonæ, the Witch Hazels (Hamamelis arborea and H. mollis), Cydonia japonica, C. j. Knap Hill Scarlet, Cotoneasters frigida and Simsonsii, Garrya elliptica, Rhododendrons arboreum, Nobleanum and præcox. Peat is not essential for Rhododendrons; they will succeed in a mixture of fibrous loam, half-decayed leaves (Oak or Beech for preference) and clean sand.

General Work.—Complete the pruning of deciduous shrubs and lightly fork over the entire area, leaving the surface rough so that it may be pulverised by the spring frosts. It should be borne in mind that early-flowering Rhododendrons will require protection should frost occur during their flowering period.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

PUBLICATIONS

The Horticultural Directory.—An exceedingly useful publication just to hand is the Horticultural Directory and Year Book for 1924.* This contains the names and addresses of all those who own gardens needing any considerable staff, as well as the names of the leading head-gardeners in Britain. This new edition should be welcome to many gardeners, as it should enable them to get into touch with old friends of whose whereabouts they have been uncertain. Here, too, will be found the names and addresses of the principal nurserymen, seedsmen and horticultural sundriesmen in England, Scotland, Ireland and Wales. Other useful information includes names of botanic gardens in the British Empire, together with the names of the officials; of the principal parks, gardens and open spaces in the British Isles and of horticultural societies. The publishers are to be congratulated on the very thorough way in which they have carried out the revision.

* "Horticultural Directory and Year Book for 1924." Published by the *Gardeners' Chronicle*, Limited, 5, Tavistock Street, Covent Garden, London, W.C.2. Price 4s. post free.

Answers to Correspondents

NAMES OF PLANTS.—W. F.—1, Cotoneaster salicifolia; 2, Litsea japonica; 3, Pinus Cembra; 4 and 9, Abies Nordmanniana; 5 and 17, Cupressus pisifera plumosa aurea; 6, Buddleia variabilis; 7, Cupressus Lawsoniana; 8, Pinus excelsa; 10, Abies cephalonica; 11, Escallonia macrantha; 12, Juniperus communis hibernica fastigiata; 13, Cupressus pisifera plumosa; 14, C. Lawsoniana erecta viridis; 15, Pieris japonica; 16, P. j. variegata.

Forthcoming Lecture.—A special lecture has been arranged to be given in the Royal Horticultural Society's Hall in Vincent Square, Westminster, at 4 p.m., on the occasion of its next Fortnightly Meeting, on January 15, by Mrs. Henshaw on "The Alpine Flowers of Western Canada." This lecture will be illustrated by means of hand-coloured lantern slides, and as it has been impossible to include any announcement of it in the Society's Book of Arrangements, Fellows and others interested should note it in their diaries.

CATALOGUES RECEIVED.

Messrs. Sutton and Sons, Reading.—Amateur's Guide in Horticulture and General Garden Seed Catalogue; beautifully illustrated both in colour and half-tone.
Messrs. James Carter and Co., Raynes Park, London, S.W.20.—General Seed List, profusely illustrated.
Messrs. Edward Webb and Sons (Stourbridge), Limited, Wordsley, Stourbridge.—Garden Seed Catalogue, with numerous illustrations.
Messrs. Herd, Bros., Penrith.—Seed List.
Messrs. Austin and McAslan, 89–96, Mitchell Street, Glasgow.—Seed List.
Messrs. Little and Ballantyne, Limited, Carlisle.—Forest, Ornamental and Fruit Trees, Shrubs, Roses, Alpines, etc.
Messrs. Hillier and Sons, West Hill Nurseries, Winchester.—Trees and Shrubs, including New and Rare Species and Varieties.
Messrs. Dicksons, Limited, The Nurseries, Chester.—Forest Trees, Ornamental Trees, Shrubs, etc., also Seed List.
Mr. Alfred Dawkins, 408, King's Road, Chelsea.—Seed List.
Messrs. Alex. Dickson and Sons, Limited, Hawlmark, Belfast.—Seed List.
Messrs. W. Drummond and Son, Limited, 57 and 58, Dawson Street, Dublin.—Seed List.

THE GARDEN

No. 2722.—Vol. LXXXVIII.] [January 19, 1924.

PRIMULAS FOR THE COOL GREENHOUSE

It is in these early days of the year that one appreciates to the full the species and varieties of Primula commonly grown in greenhouses. Most of the kinds so cultivated are not naturally of brilliant colouring, P. floribunda and the rather later-flowering P. verticillata, both with bright yellow flowers, being exceptions in this respect. The florist has succeeded, however, in endowing Primula sinensis and its form (if form it is) stellata, with rich and clean colouring far removed from the dull rose characteristic of the plant. Great things have been achieved, too, with Primula obconica and P. malacoides, and it is not too much to hope that the day is not far distant when the wonderful colour-range of Primula sinensis shall be theirs also.

Primula sinensis as introduced to this country was already a garden plant, and no wild specimens of it have ever been collected. It was for a while assumed that the beautiful soft lilac species now known as P. calciphila, collected on the cliffs of Ichang, China, was in fact the long-sought wild form of Primula sinensis, but apart from the fact that it refuses even to hybridise with the cultivated forms of P. sinensis, there is really very little about the appearance of the plant to justify the supposition. It is as certain as anything can be that is not capable of logical demonstration, that the typical Primula sinensis was of a not over-bright bluish rose hue. Leaving controversy aside, however, everyone with a greenhouse and a love of the gracious would do well, if they can procure seed, to grow P. calciphila.

Primula sinensis is a species of particular interest to those scientists whose speciality is the study of genetics, and despite an immense amount of research work, the application of the laws of heredity to the species is by no means completely unravelled. Nevertheless, the researches have greatly facilitated the work of those who specialise in the raising of new varieties, and it is really remarkable how easily a new variety with given characters may, as a rule, be produced, yet certain forms, the product of first crosses, which are particularly attractive, can never be anything but chimæra, doomed to fade with the passing of the plants.

When first "crimson" Primulas were introduced, the term was very much a courtesy one, but the passing of the years and long-continued labour have brought forth forms of ever-increasing beauty and purity of colouring until to-day there remains in the present strain of Sutton's Improved Crimson King, for instance, no more "blue" than is necessary to make it a real crimson. The almost blood-crimson of the flowers of Etna, too, is combined with splendid purple foliage and leaf-stems.

Apart from the crimson shades, the biggest advance has been in the coral pink varieties which originated spontaneously from the crimson varieties, just as somewhat similarly coloured varieties have appeared in the hardy Primulas pulverulenta and japonica. The pink form apparently arises in all these cases by the loss of a "factor" which controls to some extent the vigour of the plant as well as the colouring, inasmuch as the coral forms are always less vigorous in growth and more susceptible to cold. For this reason they should be housed rather sooner than the other colour forms, and if grown on to flower in the same structure, should have the benefit of the warmest corner.

The "blue" varieties of this plant are still pretty much where the crimsons were a couple of decades ago; there is nothing approaching a real blue at present, and it may be that there never will be. The particular tones of purple affected by the species are not too pleasing either, unless very much diluted. It thus comes about that the most attractive of the "blue" tones is the palest of the three shades usually grown—and typified by Reading Blue. Whites as pure as may reasonably be expected—as pure, indeed, as are wanted—in the World of Flowers are obtainable, both with pale green stems and leaves and with the more robust-looking dark stems and foliage.

Every colour form, whether it first originated with the typical palm-like foliage or with the newer long type which is supposed to be fern-like, can readily be reproduced with the other type of foliage.

Primula stellata is usually considered to be no more than a form of P. sinensis and, botanically, there can be little doubt that both belong to one species, but the two distinct forms as we know them to-day were introduced together now more than a century ago and continue to reproduce true to type. Every colour known in the typical sinensis can be duplicated in the Star class, while, in addition, we have now the snow white eyeless form known as Silver Star illustrated on page 30. The absence of the "eye" so characteristic of these Primulas makes the flower startlingly unlike that of any other Primula in cultivation, but the

A PLEASING GROUP OF PRIMULA MALACOIDES.

THE SOFT MAUVE PRIMULA CALCIPHILA.

THE VERY REMARKABLE EYELESS PRIMULA STELLATA SILVER STAR.

variety is none the less at once charming and effective, and equally useful for decoration as growing or when cut.

Two new varieties known as Symmetry and Giant White Star, the former having deep rose blossoms, represent a new type which combines much of the form and substance of the sinensis varieties with the vigorous and more graceful habit of the stellatas. They are destined to become very popular.

Whatever doubts exist as to the wild type of Primula sinensis, there is none as to that of Primula malacoides, which was not introduced from Yunnan until 1908. So steady and so rapid has the improvement of this plant been, however, that we are in some danger of forgetting what the wild species is like. The height of the plant and the size of the blossoms have been doubled, the rather dingy colouring has been brightened, we have pure white and rosy forms and last, but by no means least, very effective double ones. The species is very nearly hardy, and its culture may be successfully attempted in any house from which frost can be excluded. The illustration at the top of this page shews how decorative a small group of this plant may be.

Turning now to Primula obconica, which was introduced in 1882, a very great improvement has, once again, followed the labours of the florists, yet is this species far less amenable to their "blandishments" than P. malacoides. A crimson malacoides we may expect in the not distant future; a crimson obconica we nominally have, but it has some way to go before it lives up to its name, and pure white ones are rare and cannot be depended upon to come true from seed. The flower has a natural tendency to come a cold lavender, and the florists seem, perversely, to have concentrated most of their attention upon getting it warm rose or red, whereas an effort to raise a strain of the clear pinkish lilac or china pink of P. calciphila might probably have been successful and would be far more desirable. The efforts to produce a blue obconica have met with some success, though the "blues" so far produced are called so only by courtesy. Efforts to cross the species with P. sinensis do not appear to meet with any success, though a broad-leaved, robust form called Eureka is reputed to be the result of such a cross. These robust but not very free-flowered plants, however, seem to "throw-out" occasionally where no question of cross-pollination can arise and appear to represent a natural development.

Primula obconica continues in flower for a long time and, by sowing for successsion or by keeping back some of the plants—it is a perennial—may be had in flower all the year round. It is, despite its limited colour-range, an attractive plant and an easily grown one, but unless one has proved oneself immune, it should be handled with caution, as the glands on the undersides of the leaves produce on some people an irritating, even dangerous, rash. All plants grown under glass object to sudden changes of temperature, but some feel the change more than others, and Primula obconica is one of those to which a considerable fall, if not fatal, is at least very serious. It is possible, even desirable, to grow the plant in a cool house—it will often winter safely outdoors—but if taken from a fairly warm structure to a cool conservatory it will immediately begin to languish.

Of the yellow-flowered greenhouse Primulas, the most generally useful is P. kewensis, which represents the result of a cross between P. floribunda and P. verticillata. It is a good perennial and easily increased by division. There is a very attractive paler form of Primula floribunda, too, called P. floribunda grandiflora Isabellina.

Digitized by Google

There are a number of other charming species which are barely hardy in this country and which are suited in a cool, or even cold, greenhouse. Primula Winteri, which flowers at this season, is one; P. Forbesii, like a miniature malacoides, another; while kinds like marginata and some of the forms and hybrids of P. hirsuta show to advantage under glass. These, however, hardly come in the same category as the species previously described, and to mention their names must suffice.

The culture of these greenhouse Primulas presents no serious difficulties, though P. sinensis in both forms has an objection to leaf-mould. In order to get this species into bloom for early January, when flowers are apt to be scarce, it is well to sow about the middle of June. A little bottom-heat may be afforded the seeds, but it is not necessary; good plants can be and have been raised from sowings in a cold greenhouse, and if this is made about early April, nice plants should result which will flower in autumn and, if protected from frost, last till Christmas or after. The seeds, which are comparatively large, germinate irregularly, and they should, therefore, be sown thinly. Primula obconica has the same objection to leaf-mould.

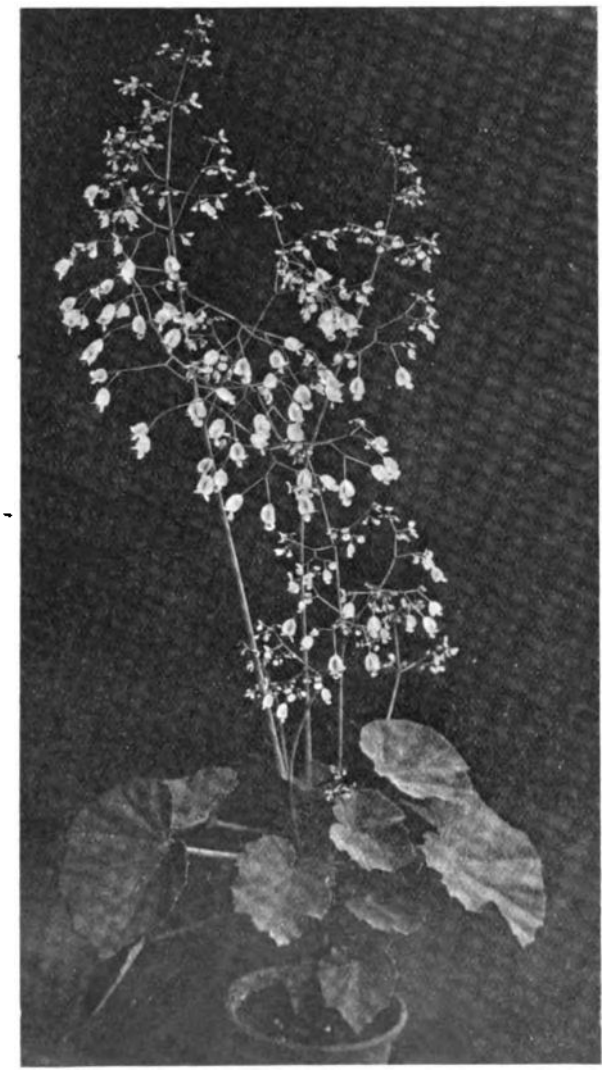
Primula malacoides makes soft growth and is rather subject to "damping off." A buoyant atmosphere and care in keeping water out of the crowns go far towards preventing this trouble. Care should be taken, too, with P. sinensis, as this also will "damp" under bad treatment. Keep the crowns of the plants clear of the soil when potting.

THE CULTURE OF THE BEGONIA.—III

THE fibrous-rooted Begonias are just as interesting and even more varied in flower and foliage than the tuberous-rooted forms. Everyone knows B. Gloire de Lorraine, one of the parents of a wonderful race of double and single winter-flowering forms, appreciated alike for pot and basket work. B. Rex, with its marvellous foliage, also enjoys wide popularity; while B. semperflorens is a notable bedding plant.

In view of the diverse habits of the kinds mentioned (and these are but a small part of the available range), it is obvious that very different methods of culture will be necessary. Gloire de Lorraine, as typical of the wide and important range of winter-flowering varieties, will have first claim. These are capable of very rapid propagation, for not only can the usual mode of increase by cuttings be used, but a vigorous plant may be raised from every adult leaf. Although one may undertake their propagation at any season of the year, February is the best time to select when winter-flowering plants are the object. The first step is to prepare some older plants by cutting them back some weeks previously. These, if cut down to within a few inches of the soil and well rested by a limited use of water, will send up a liberal supply of soft, short, young shoots about 3ins. or 4ins. long, which are just what are required for the basis of young stock. These should be detached from the parent by severing with a sharp knife just beneath a joint. Freely drain the pots in which it is proposed to insert these, and fill with a compost of two parts of loam to one each of leaf-soil and silver sand. Several cuttings may go into each pot and the base of each should rest upon a small heap of sand, which greatly hastens the formation of roots. Insert the cuttings firmly and then water well, and place the pots in a gentle bottom heat of about 60° Fahr., and keep close and moist until rooted. Do not over-water, and keep a sharp watch for decaying leaves, which should be promptly removed. When roots have been formed, remove the plants to a cooler position and allow plenty of light, although direct sunshine should be screened. Free spraying with tepid water encourages growth, and as the little plants grow they should be potted off into single pots.

Do this potting fairly firmly and keep the young plants in a night temperature of 55° to 60° Fahr., with a rise of from 5° to 10° during the day. Continue to syringe lightly overhead, and, when the small pots are filled with roots, transfer to a larger size. For the second and all subsequent pottings, use the following compost: Equal parts of fibrous loam and peat, with a quarter part each of leaf-mould, cow manure, bonfire ash and coarse sand. Through the whole summer it is important to shade when the sun is bright:



THE GRACEFUL WINTER-FLOWERING BEGONIA MANICATA.

keep the roots moist and give plenty of air, but take pains to avoid draught. When flowering begins in late autumn, feeding may be commenced, though care should be taken that buds are not permitted to develop until a good plant has been built up. Where stock is scarce and leaf propagation is adopted, fully developed leaves should be chosen, and these should be taken off with the leaf stalk and inserted in similar sandy soil to that advised above. Follow similar cultural conditions, and small shoots will soon be seen springing up from the base of each leaf, which, when strong enough, may be potted off as new plants.

Similar methods of propagation may be applied to BB. Haageana, metallica, weltoniensis, etc., though it should be noted in the case of the last named that this forms a tuber from which new growth springs annually, and thus the plant is capable of being grown on to an immense size. The type represented by B. semperflorens may also be propagated by means of cuttings, but a far more satisfactory method (where large quantities are needed) is to sow a packet of seeds under conditions described for the tuberous forms. The seed of Begonia semperflorens germinates (if fresh) with extraordinary freedom, and the little plants soon reach the flowering stage, so that a sowing made in January or February will produce splendid little plants for putting out in late May or early June. This species is far more of a sun lover, particularly in its bronze-foliaged forms, and a very sunny position should be given to the plants. Here the plants will form an ever-thickening belt of colour.

Finally, in a class by themselves, we come to the glorious Rex varieties, with their giant heart-shaped leaves so marvellously zoned, blotched and reticulated, with silver, olive, pink, etc., with very prominent red veins. The flowering qualities of these are negligible, but the gorgeous leaves place them in the front rank of warm greenhouse and conservatory plants. They do not appreciate sunlight, and are, indeed, shade-lovers. For bold pans too, they are simply superb—and I want you to mark that word "pan," for the Rex Begonia does not root deeply.

There is one point to which attention should be paid in their successful culture, and that is the need for fairly frequent replanting. The stems, which are thick and woody, are constantly elongating and rising higher and higher; hence the need, if neat and shapely plants are to be maintained, for lifting and replanting at a lower level. Neglect of this not only gives one ragged-looking examples, but inevitably results in smaller leaves. New roots evolve after replanting which greatly increase the absorbing power of the plant, hence the larger leaves which follow. While it is easy enough to obtain an increase of the plants by division, do not forget, where stock is short, that young plants can be obtained from the older leaves. Take off a fully developed leaf, in early summer, and nick the thick mid rib here and there. A pan should next be filled with light open soil surfaced with a good layer of coarse silver sand. Peg or weight the leaves into contact with the soil at the nicked places, and in course of time small plantlets will make their appearance, well furnished with roots, and these can be taken up and grown on into large plants within the space of a few months. H. W. CANNING-WRIGHT.

(To be concluded.)

Digitized by Google

THE MEADOW RUES

THERE are about fifty species of the genus Thalictrum which have been found distributed over the Temperate and Arctic regions of the northern hemisphere, with a few in the Andes of South America. The genus belongs to the Natural Order Ranunculaceæ, and is closely allied to Anemone. The flowers of the plants of this genus have no petals, but they have four or five petal-like sepals, which in some species—T. Delavayi, for instance—are large and attractive, but in others, like T. minus, are small and inconspicuous, and fall so quickly that the flowers appear to be all stamens. There are several excellent garden perennials among the Thalictrums very useful for flower border, waterside or woodland, while two or three species may well find a place in the rock garden on account of their dwarf elegant habit and showy flowers. Our native species, T. flavum, was probably one of the earliest in cultivation in our gardens. It has handsome foliage and yellowish flower-heads, but there are several others now grown that are much more attractive.

One of the latest arrivals—T. dipterocarpum from China—is a handsome plant of tall, graceful habit and with pretty rose purple flowers. There are also several pretty Himalayan species, but on the whole they are more difficult to grow in this country than the European and North American kinds. These latter are easy to manage, and will grow in any good garden soil, while some of the more robust kinds will hold their own in the wild garden.

All Thalictrums may be propagated by dividing the roots in autumn or early spring. Plants may also be raised from seeds, but these, in common with those of many other members of the Order, are naturally slow and irregular in germinating, two years sometimes elapsing before they all sprout. As a rule Thalictrums thrive best in half-shady situations, but at the same time they are quite happy in an open sunny border if the soil is deep and well tilled. The following are the best kinds out of a large number:

T. ALPINUM.—The smallest plant in the genus, this little alpine is found wild on the mountains of Scotland and Wales, growing in rocky places among the short turf. It is also spread over the mountain chains of Europe. Very suitable for the rock garden, it is a pretty little species with an upright stem some 3ins. high, finely divided leaves and delicate, feathery, nodding flowers in July and August.

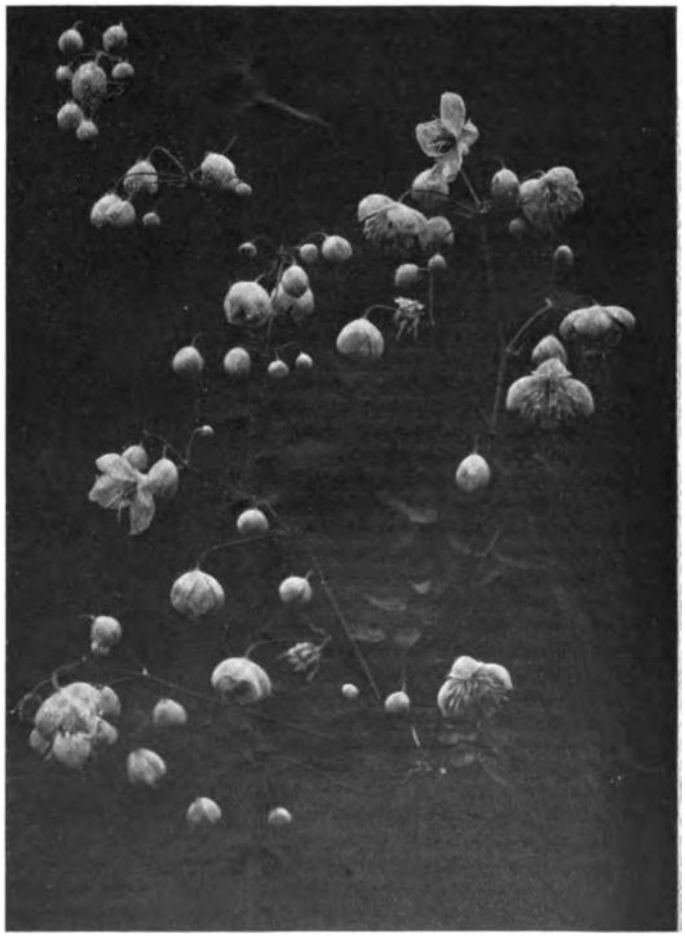
T. ANEMONOIDES (syn. Anemone thalictroides).—The Rue Anemone is a dainty little American plant that is best suited for the rock garden in partial shade, where the soil is moist and deep but well drained. It has tuberous roots, three-lobed adiantum-like leaflets, and panicles of white flowers that more resemble those of Anemone nemorosa than of a Thalictrum. The plant is slender in habit, rarely exceeding 6ins. in height and flowers in April. It is also a choice species for the alpine house, and may be successfully grown in pans in gritty soil with plenty of leaf-mould. It is native to the whole of North America, being found in every part of that country from Virginia to Canada. It was introduced into England in the year 1768 and is quite hardy. There is also a form with double flowers.

T. ANGUSTIFOLIUM.—This is a sturdy plant that grows about 6ft. high, with numerous stems, and pretty, narrowly divided foliage, overtopped by a foamy mass of pale yellow flowers in feathery panicles. The colouring is derived from the stamens only, the sepals being inconspicuous. This handsome border plant, of which the principal asset is its light elegant habit, is a native of Europe.

T. AQUILEGIFOLIUM.—The Feathery Columbine is a very ornamental species that has long been grown in our gardens. The typical form has yellowish flowers in flattened panicles, consisting mainly of stamens formed into foamy masses. The stems are hollow, purplish, and are furnished with broad leaves resembling those of the Columbine. These leaves vary in tint, but are more or less glaucous. Several garden forms have been produced differing mainly in the colouring of the inflorescence. Of these the best are album (white), atropurpureum (dark lilac) and roseum (pale rose). All these forms average 3ft. in height, and, when fully established, produce many stems and masses of feathery flowers in June. They will thrive in any soil, but prefer a strong loam with plenty of moisture, and are excellent border plants for bold groups.

T. CHELIDONII.—The chelidonium-like Meadow Rue is a Himalayan plant of slender habit, about 2ft. high, with ternately divided leaves that are pale green above and glaucous beneath. The lilac or purple flowers with conspicuous sepals are 1in. in diameter, and produced in large panicles with rigid branches during July and August.

THE PINK FORM OF THE FEATHERY "COLUMBINE," THALICTRUM AQUILEGIFOLIUM.



THE INFLORESCENCE OF THE BEAUTIFUL THALICTRUM DIPTEROCARPUM.

Digitized by Google

It is a shade-loving plant and should be grown in the rock garden.

T. DELAVAYI.—One of the best, this Chinese species is of slender growth, having thin, wiry stems 3ft. high, and slight airy panicles of mauve-tinted flowers nodding among the maidenhair-like foliage. It should be grown in light, moist, sandy soil, and is more suited to the rock garden than to the border. It forms a loose bush studded in July and August with numerous flowers. It was introduced from Yunnan in Western China in the year 1890.

THE RUE ANEMONE, THALICTRUM ANEMONOIDES (=ANEMONE THALICTROIDES).

T. DIPTEROCARPUM.—This is a distinct and beautiful new species from China which is becoming well known in gardens. It was introduced by Messrs. Veitch and Sons through their traveller, E. H. Wilson. The persistent sepals are ovate, reddish violet or rose purple in colour, and contrast well with the pale sulphur tone of the stamens. In some respects it may be likened to an improved T. Delavayi, but it reaches a height of 8ft. or more in strong loamy soil of a gravelly nature, and produces large lax panicles of numerous nodding flowers in July. It is one of those species with large sepals, four to each flower, the whole being nearly 1in. in diameter. It was given a first-class certificate by the Royal Horticultural Society in July, 1917. There is also a pretty white-flowered variety now in cultivation.

T. FLAVUM.—This is a familiar plant in the hedgerows of many parts of this country, and makes a useful border plant for bold grouping. The stems reach a height of 6ft., being clothed with grey-green, much-divided leaves, surmounted by feathery panicles of yellow flowers consisting chiefly of stamens. It will grow almost anywhere, amid shrubs, or by the waterside, as well as in the wild garden.

T. GLAUCUM.—A very vigorous perennial, with stout, purplish stems reaching a height of 7ft. or more and glaucous leaves that are somewhat triangular in outline. The inflorescence consists of a flattened panicle of soft yellow flowers 2ft. or more across, due to the freely branching stem. It is a border plant with a bold, handsome appearance, very imposing in large groups or in isolated beds. It flowers in June and July, and is a native of South Europe. There is a form of this species known as T. flavescens, with green leaves, not glaucous, and paler yellow flowers.

T. MINUS is one of our native plants, being found in many rocky districts in this country. It is very variable in habit, and there are several pretty forms of it well worth growing. T. m. var. adiantifolium is a dwarf bushy plant 18ins. high, with minutely divided leaves of a bluish green tint and slender panicles of greenish yellow flowers. T. m. var. elatum grows 5ft. high, forming an elegant bush, surmounted by a cloud of greenish yellow flowers in July. It is very useful either as cut flower or foliage for table decoration. T. m. purpurascens has purplish tinted flowers.

T. ORIENTALE.—This is an Eastern species, being found in the fissures of rocks in the mountainous regions of Asia Minor. It is under 1ft. high, with biternate leaves of fair size, and loose panicles of white flowers ¾in. in diameter. It is somewhat rare in this country, and should be grown in rocky soil in the shady rock garden.

T. PETALOIDEUM.—This species, which hails from North-Eastern Asia, corresponds to the North American T. anemonoides. The sepals of this species are white, and longer than the stamens; and though they soon fall, the filaments of the stamens are so much dilated as to look like little flesh-coloured petals with a yellow anther at the tip of each. In this species the tubers differ from those of T. tuberosum in being long, sometimes over 1in. in length, instead of being short and rounded. It makes a pretty border plant, not exceeding 2ft. in height, with many handsome flowers of good size in summer.

T. PURPURASCENS.—This North American species grows 6ft. high, and can be recommended for groups in the border or by the waterside. It has the stem and leaves of T. glaucum, and is very handsome and imposing with an inflorescence consisting of a drooping mass of purplish flowers over 1ft. in diameter at the top of each stem.

T. TUBEROSUM.—This is one of the petaloid species, with stems about 1ft. high, much-divided leaves and clusters of small, pure white flowers, produced from July to September. It is a pretty plant for the rock garden, soon forming attractive groups in half-shady situations on the drier slopes. It is easily increased by dividing the mass of small rounded tubers which form the rootstock.

Many other species might be included, but the above constitute the cream of the genus. W. I.

GRAPE VINES

Their Pruning and Cleaning.

GRAPE Vines are grown by amateurs in structures where there is, also, a miscellaneous collection of plants, as well as in vineries built specially for the purpose. Very fine bunches of Grapes are grown in these houses, sometimes in circumstances not conducive to success. The work of pruning and cleaning the rods is a very important one. If wrongly pruned, Vines soon become a mass of shoots in summertime, their condition hindering the development of good leaves and the colouring and ripening of the berries. The tendency is to leave the side spurs too close together and, also, several stumps of shoots on each spur.

PRUNING OLD OR ESTABLISHED VINES.—Before any work is done, the cultivator should observe closely the condition of the Vines. If there is more than one side shoot on a spur, cut out all but the strongest entirely and shorten the one retained to two eyes, or buds. If the spurs are closer together than 18ins., saw out some of the weakest and badly-placed spurs entirely, so that the spurs will be, on both sides of the rod, about 2ft. apart. This distance is approximate, as it is not possible to have all spurs just so far apart the whole length of the vine. To prevent bleeding, paint over each cut end with styptic or painters' knotting. Do this one or two days after pruning.

PRUNING YOUNG VINES.—Those planted during the current winter should be pruned about the middle of January, and immediately painted to stop bleeding; paint the cut ends several times. The young vine should be cut back to within 2ft. of the soil—18ins. would be better: one young leader and a young shoot on each side of the rod being sufficient to retain the first year. If it is not possible to prune young Vines before the date named, the best plan will be to plant the Vines and depress the canes. In all cases young Vines should be allowed to start new growth very slowly, with the aid of sun heat rather than fire heat. When the new shoots grow, those nearest the extreme end of the rod will push first, and, as they attain to a length approaching 1in. rub them off, continuing till all are removed down to the desired point. At this stage the cultivator should leave a leading shoot and one on each side of the rod, exactly as in the case of pruning a young rod. The denuded cane should remain uncut till about the end of July, when it may be cut out, or it may be left till the next winter pruning. To cut it out earlier would result in excessive bleeding.

CLEANING THE RODS.—I am referring to naturally clean rods, that is, to those free from insect pests. A young cane will need no cleaning; the young bark should not be cut or peeled off.

The old rod will have some loose bark adhering to it; such may be removed, but none that is adhering firmly to the rod itself. If a knife is used to remove such loose bark, care should be taken not to cut in deep enough to expose the green cambium. All that I do, and advocate, is firmly to grasp the rod with the hand and, by working the hand round the rod rub off all loose bark and leave it at that. Rods so treated swell to a good size; those unnaturally peeled remain thin and sometimes lack strength. GEORGE GARNER.

LOW-GROWING SHRUBS

Excluding Conifers.

THE subject of dwarf or low-growing shrubs, while interesting to all lovers of hardy plants, will appeal to readers with small gardens in particular. By the judicious selection and planting of shrubs of small stature, with just a few taller kinds to relieve any possibility of flat effect, at least three times as many shrubs can be readily accommodated as would otherwise be the case. The site for a house is frequently chosen because of the beautiful views of the surrounding country possible from the windows. Not only will dwarf shrubs find a place near the house, but their extensive planting, following the lines of the views, will enhance the scene. I have in mind a mansion of recent construction with glorious views over the Surrey hills. Standing at the head of a valley, the main vista is of sloping banks planted with masses of low-growing shrubs, Heaths, dwarf Rhododendrons, Cotoneasters, Helianthemums and Barberries. This is by the way, however, as such a position allows the planting of shrubs 3ft. to 4ft. or more in height, whereas the following notes deal with low-growing kinds which seldom exceed 18ins. tall. If eventually they overtop this height, it is the result of many years growth. Should the bushes shew signs of too vigorous shoots, a little trimming with a knife will soon put things to rights.

There is much to be said in favour of planting more dwarf-growing shrubs towards the front of shrubbery borders. This will do away with a vast amount of pruning and also with the crowded appearance, which too often is the most noticeable feature of these borders.

In the rock garden dwarf conifers usually find a place, not only because of their effectiveness in winter, but because of the contrast they afford to the many flowering species grown there. There are numerous other hardy shrubs of dwarf stature, both evergreen and deciduous, equally suitable for planting with rock plants, however, and which add variety, attraction and interest to the rock garden. The following notes draw attention, moreover, to a number of showy kinds admirably adapted for terrace or other formal gardens.

Quite a number of the shrubs brought under review can be cultivated in pots for use in window boxes, either throughout the year or for the winter season, giving place to "Geraniums" and Fuchsias in summer.

A few of the shrubs noted are dwarf forms (abnormal varieties) of larger-growing kinds, but, unlike most of the dwarf conifers, the low growth is their normal habit. They are on that account easy to propagate for the most part.

With regard to soil, except that the Heaths and Rhododendrons require a lime-free soil, the majority thrive in ordinary garden soils which have been well dug and manured. For sunny banks where the soil is light and sandy one should give particular attention to Helianthemums, Cotoneasters, Dwarf Brooms and Barberries.

EVERGREEN SPECIES AND VARIETIES.

Arctostaphylos Uva-ursi (Bearberry) is a trailing evergreen mountain shrub native of Northern Britain and Central Europe. It prefers moist, cool conditions and is admirable hanging over boulders in the rock garden. The long trailing shoots are quite at home, too, in the foreground of shrubbery borders where Rhododendrons thrive. The terminal clusters of drooping pink blossoms are borne from April onwards, and are followed by small red, globular berries. Seeds and cuttings provide ready means of increase, but trailing over suitable ground, the stems root freely, giving an abundance of rooted layers.

There are two forms of Berberis buxifolia—var. nana and var. nana compacta—of tufted habit and pretty as isolated specimens in the rock garden or grouped several together along the front of a border. The plants are normally evergreen, but the species, being a Chilian, severe frosts cause many leaves to fall. B. candidula (hypoleuca) is a slow-growing bush of neat close habit with dark green leaves which are noticeably grey-white beneath. It may grow eventually to 2ft. in height, but is readily kept to half this height by the free and annual use of the secateurs. B. nervosa is one of the Mahonia group, and a very attractive dwarf shrub with handsome pinnate leaves often as long or longer than the height of the plants, which averages from 12ins. to 18ins. The erect racemes of yellow flowers are attractive, so also are the clusters of purplish blue fruits. Seeds afford the best means of increasing this dwarf Mahonia of Western North America.

The Creeping Barberry, B. repens, also from Western North America, has smaller leaflets and dull green foliage, at least as compared with the previous species, but the creeping stems give the plant an inviting tufted habit, and it bears rich yellow flowers in spring and blue-black fruits in late summer. There are several dwarf forms of the beautiful hybrid Barberry B. stenophylla, the most valuable for the purposes under review being Irwinii and reflexa, with showy golden yellow blossoms in April and early May.

Bruckenthalia spiculifolia is an Ericaceous shrub native of the mountains of Eastern Europe and Asia Minor. Forming a carpet of growth 5ins. or 6ins. high, the pink-tinted blossoms are borne in terminal racemes during June. It thrives under similar conditions to the Heaths, and may be increased by seeds and cuttings.

DWARF BOX.

For certain positions several dwarf forms or varieties of the Common Box, Buxus sempervirens, are worthy of attention. The smallest is var. myosotifolia, a dwarf, slow-growing shrub of dense habit with tiny leaves; var. myrtifolia, which becomes eventually a slightly larger bush, but still of dwarf tufted habit and with narrow leaves. The popular Box Edging or Edging Box—var. suffruticosa—is a valuable shrub for formal gardening being readily trimmed or clipped to any small design, but it is worth cultivating naturally, when it forms as a small bushy shrub. The Chinese Box, Buxus Harlandi, is naturally a small evergreen bush of rounded formal habit. As a dot plant plant in the rock garden, for window boxes and flower-beds in winter the Chinese Box should find a place among the best half-dozen evergreen shrubs.

The many forms or varieties of the Common Ling, Calluna vulgaris, provide a wealth of colour from August to October. They vary in height from the 2ins. or 3ins. of var. pygmæa upwards. Var. alba minor is a dainty white-flowered plant of 5ins. or 6ins.; var. aurea has gold-tipped foliage, while that of var. cuprea has a bronzy tint; both grow from 6ins. to 9ins. tall. Var. argentea with silver-tipped growths; var. Serlei, one of the best whites with a mass of shoots about 9ins. high; var. flore pleno with rosy purple double blossoms and notable for the long period of flowering; var. Alportii, the best of the vigorous crimson-purple forms, 15ins. to 18ins. in height; and Hammondi, one of the freest and taller white varieties (18ins.) are others of special merit.

COTONEASTERS.

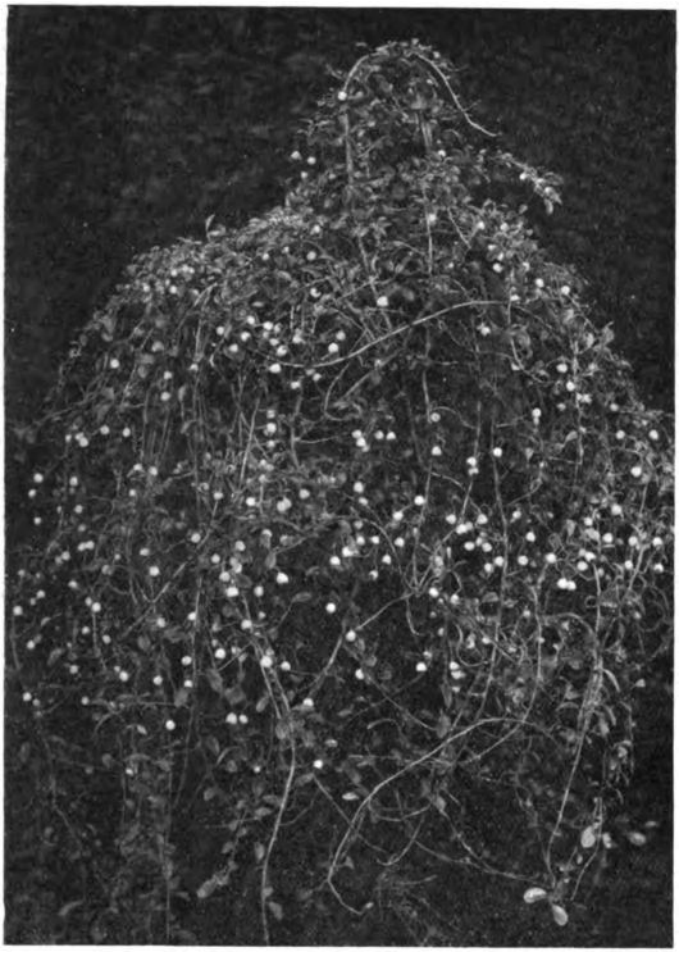
Because of their easy culture in nearly all soils, even those which are poor and stony, the Cotoneasters are very useful for banks and large rock

A GOOD DWARF FORM OF BERBERIS STENOPHYLLA AT HALLINGBURY.

Digitized by Google

gardens. C. congesta, sometimes named C. microphylla var. glacialis, is a slow-growing dense little alpine shrub with foliage a paler green than that of C. microphylla. The latter is more vigorous and spreading in habit, with small glossy green leaves and showy red fruits. C. thymæfolia, which may also be a form of microphylla, has neat glossy green leaves, and the plants are of dense branching habit with scarlet fruits. These forms vary from seed, hence those of distinct and desirable habit should be propagated by layering or from cuttings. One of the introductions from China by Mr. E. H. Wilson (1900), C. humifusa (syn. Dammeri var. radicans) clings closely to the ground or rockery boulders if suitably placed, and is certainly one of the most distinct trailing shrubs of recent introduction; the fruits are coral red and very showy.

The Common Irish, or St. Dabeoc's Heath, Daboecia polifolia, rosy purple, and the three forms var. alba, var. atropurpurea and var. bicolor are even more attractive for planting in masses than the Common Ling. The flowering season extends from June or July to October. It is worth while lightly to clip over the plants in February to keep them low and bushy.



COTONEASTER HUMIFUSA (C. DAMMERI RADICANS).

The Daphnes are among the choicest of dwarf shrubs, their fragrant blossoms appealing to flower-lovers. D. Blayagana is a favourite rock garden shrub; stones should be placed on the branches as they spread. The dainty heads of creamy white blossoms are freely borne during March and April. The Garland Flower, D. Cneorum, is under happy conditions smothered with rosy pink blossoms in April and May, its height 9ins. to 1ft. A third species, D. oleoides (Fioniana), is an erect-growing bushy shrub with lilac rose blossoms in spring, and of an average height of 18ins.

THE HEATHS

provide a wealth of low-growing shrubby plants in flower more or less throughout the year. Except for the easy E. carnea a lime-free soil is desirable, otherwise the Heaths can be massed on slopes and banks with beautiful effect. The first, or last, to flower is E. darleyensis, which in mild weather opens its first flowers in November and continues until April. The buds of E. carnea and its named varieties open with the first weeks of the year. E. ciliaris and variety alba, E. cinerea and several varieties, E. Mackayi and double form, E. Maweana, E. Tetralix and var. alba, and the Cornish Heath, E. vagans, with several forms are admirable for planting in colonies.

Several forms of Euonymus radicans are useful in most soils and positions. Var. variegata with prettily silvered foliage is valuable as a carpeter, also as a plant for edging beds and borders; it stands frequent clipping. The variety Silver Queen is an adult form and very showy in masses. The Creeping Wintergreen, Gaultheria procumbens is a dwarf close-growing shrub with dark glossy green leaves, thriving in sun or shade, and producing plenty of red berries in autumn.

For light soils and sunny exposures the Sun Roses, Helianthemum, produce a profusion of blossoms in summer. They can be freely increased by cuttings in late summer under bell-glasses and hand-lights. The forms of the Common Sun Rose, H. vulgaris, can be readily raised from seeds, but as they hybridise freely the named sorts should be propagated by cuttings. The Bride, Golden Queen, Rose Queen, Mrs. Earle, Fireball and cupreum are six of the best. H. algarvense, H. alyssoides, H. formosum and var. unicolor all have yellow blossoms and H. umbellatum, white.

The dwarf Lavenders are invaluable for paved and old-world gardens, thriving best in well drained soils. Lavandula vera nana compacta flowers two or three weeks earlier than the Common Lavender, and has larger individual flowers on the spike of a deeper blue. A variety sold in nurseries as Dwarf Blue is paler in colour, its particular value being the grey foliage in winter.

A. O.

To be continued.)

FORTHCOMING EVENT.

January 24.—Annual Meeting and Election of the Gardeners' Royal Benevolent Institution, to be held at Simpson's, Strand, London, W.C.2, at 2.15 p.m.

PLUMS FOR CULTURE IN POTS

THE remarks of "S. O. K." in the issue for January 5, page 9, induce me to pen a few notes about the cultivation of Plums in pots, for of all fruits abundant in juice and sugar, none can beat the product of a Gage Plum tree. A cold glasshouse will answer their needs for setting purposes, and with a mixture of varieties, fertilisation should be assured. The compost should be a mixture of fibrous loam three parts; mortar rubble, quarter part; bone-meal, quarter part; crushed charcoal, quarter part; and Peruvian guano, quarter part, with a sprinkling of flowers of sulphur over the whole. Pots 10ins. to 12ins. in diameter will be ample in size for their requirements for two or more seasons. Firm the soil as potting proceeds, but do not make it too tight, or porosity will be endangered.

Prune carefully, as observation of growth and common-sense should guide the pruner's knife. Summer pruning must be studied in close detail, this being very important for the formation of fruit-spurs. Plunge the pots in ashes during the summer months to curtail severe evaporation.

After many years of observation I recommend the following sorts as being suitable in growth for the purpose and in every way of first-rate quality:

DENNISTON'S SUPERB GAGE is a delicious Plum of first quality and size, skin pale yellowish green with a few purple blotches and dots, flesh yellow, firm, juicy and rich. This is a great bearer and very hardy, and altogether a variety of great merit. Introduced to commerce about 1835, it is still one of the best.

OULLIN'S GOLDEN GAGE is a very productive sort, perhaps not quite so full of juice or so rich in sugar as some, but nevertheless a fine variety for pot culture, the fruit being of large size for a Gage and roundish oval, and the skin greenish yellow with light bloom. It is a first-rate bearer, and has the reputation of being self-fertile.

MONARCH, a noble and self-fertile Plum of excellent character, and one to be sought after for every garden, being a huge cropper and suitable both for the kitchen and dessert. For pot purposes it is really decorative. I have seen trees measuring about 6ft. in height and a yard in diameter carrying nearly two hundred luscious fruits. These are deep purple in colour and oval in shape, though some of them, I have noticed, are almost globular.

OLD TRANSPARENT GAGE is a delicious Plum and a free bearer. The growth is of a rather straggling habit, but by judicious pinching and pruning of the growths this can largely be overcome. The fruit is medium in size, round in form and yellowish green in colour with red dots, the flesh sweet and juicy.

EARLY TRANSPARENT GAGE bears luscious fruits, and is a great favourite in all well ordered gardens, being one of the very best of the early Gages. It is splendid for pot purposes and certain to give satisfaction. The fruit is medium in size and roundish, coloured apricot yellow with crimson spots, the coloration being exceptionally rich. It is very juicy and sugary and, being self-fertile, gives general satisfaction for pot purposes.

COMTE D'ALTHAN'S GAGE is a variety similar to Green Gage in shape, but red-purple in colour, the flesh very firm, richly flavoured and juicy, with a rich honeyed excellence rarely found in Plums. It is very prolific, and must be counted among the six best Plums for pot purposes.

Digitized by Google

BLUE ROCK is a Plum of general utility, a great cropper, and useful both for dessert and cooking. It is medium round in shape and deep purple in colour, the flesh yellow, juicy and sweet. I have seen small trees in 10in. pots carrying a huge crop.

BRYANSTONE GAGE is a large late Green Gage of desirable qualities, being excellent in flavour and most valuable as a pot tree. This variety will stand feeding liberally after the setting of its fruits. A weak solution of manure water mixed with bone-meal and applied before watering, will help the trees over the stoning period. All stone fruits require lime in addition to their food, and it is well to let them have both on the little and often system.

JEFFERSON GAGE is the largest of all Gages, and very rich in flavour. The fruit is oval, golden yellow with reddish spots, and equal in flavour to any fruit grown. This should be given the warmest end of the house, and it is usual to run a rabbit's tail over the blossoms. Make sure that there is ample pollen, taken from another variety, on the fur before touching the Jefferson blossom. This process is conducive to perfect fertilisation, and it would do no harm lightly to touch all blossoms as the sun passes the meridian each day until the setting of the fruit has been completed.

The above-mentioned sorts will, I think, be found an excellent selection for the purpose named. GEO. LOVELOCK.

USING VEGETABLE RUBBISH

IN our efforts to counteract the extreme porosity of a sharply drained soil and so conserve as much moisture as possible during the growing months we have for many years relied very largely upon decayed vegetable matter. This material when wholly or partially ripe is used for all manner of purposes, such as the mulching of shrubs, including Rhododendrons and other ericaceous kinds, top-dressing herbaceous borders, rock garden and lawn, as well as in the kitchen garden as a supplementary organic fertiliser. Indeed, it has been employed for a good many years for the growing of vegetables, to the entire exclusion of animal manure, save poultry guano, and results have been extremely satisfactory.

We generally manage to have three heaps of this "stuff" on hand, so that while one, the oldest, is being used, another is maturing and a third in process of accumulation. This last, naturally, receives most attention during autumn, for it is then that suitable contributions are most plentiful. Among these, fallen leaves are the most valuable, but few things that will decay are consigned to the wasteful bonfire. In addition to leaves there are path cleanings, any weeds, other than such indestructible roots as Couch, Coltsfoot and the like, grass mowings, verge trimmings, turves, pea and bean straw, the clearings from herbaceous borders, any soft trimmings from hedgerows and shrubs, old packing straw which comes round the nurserymen's bundles, seaweed if one can get it—anything that will respond to the process of decay in a reasonably short period, is carefully collected. Even such woody growths as the stems of border Phloxes, Delphiniums and Michaelmas Daisies will make useful material.

All the year round, whenever any garden work is being done, the compost heap is growing beneath the rubbish that the garden casts off, rubbish that will, in less than twelve months time, be returned to it in the form of sweet vegetable mould, moisture-conserving and nutritious.

Where natural hollows occur, as in out-of-the-way spots in the woodland, these make first-rate places for the reception and preparation of this refuse. Failing these, a spare corner of the kitchen garden may be requisitioned for the purpose, or one may have to construct a special "pit," as we have done in the case of one heap. But even if this is actually in the garden it need not be an unsightly object. The one referred to is about 2ft. deep and 10ft. broad and long. It is surrounded on two sides by a low, ivy-clad wall, on the other by a thicket of Pernettyas, and it fronts to the path for convenience.

No lime is ever used in making our vegetable mould. This element is avoided not only because it would render the compost unsuitable for plants objecting to it, but because lime tends to destroy humus, which is the very thing we most devoutly wish to create and preserve. Instead of lime, salt is occasionally sprinkled over the growing heap, and any soot that is available also goes into the pie. A little gritty matter, such as sand from the roadsides, or path scrapings, is added now and then, more particularly in autumn when leaves are being gathered. This is not essential, but it prevents the leaves being blown away in dry weather, and I always think it assists in the acceleration of decay by giving the heap the weight, or pressure, it usually lacks.

When the heap is completed it is left to stand for about two months. After this all unrotted material from the top and sides is removed and put underneath, while the remainder is being thoroughly turned over. This is done somewhat on a simple trenching or double digging principle, a sharp spade being used to cut out each section, thus severing any woody material that may be only partially decayed. Another sprinkling of salt and more soot, if there is any at hand, are given during this operation, and the heap is then worked up into a ridge shape and beaten over with the back of the spade.

At this stage the material will be in a half-rotted condition, and after the lapse of another two or three months its contents, having been turned over a few days previously, will be quite ripe enough for mulching shrubs, digging into vegetable ground or putting into drills for Potatoes, etc. Indeed, it can then be applied to most purposes, other than top-dressing borders and the rock garden, for which an older sample will be better.

Generally speaking, a refuse heap completed in, say, December will be ready for all-round use early the following autumn, but a good deal will always depend on the nature of the material and the attention it gets. There is no doubt that salt speeds up decay, as does seaweed. Both have fertilising and anti-pest properties not to be regarded too lightly, and they are of material assistance in conserving moisture in summer. No less may be said of fresh soot, and the effect this has in darkening the mould is helpful in dry gardens where the loam is light in colour as well as light in texture.

By adding a sprinkling of poultry manure on the heap as it accumulates, one may also hasten decay and render the finished product a good deal more stimulative. As a matter of fact, vegetable refuse properly prepared with the addition of this manure will be found equal to most farmyard "muck" for garden crops generally, it being particularly efficacious in the growing of the Brassicæ, Spinach and salad vegetables. Theoretically, perhaps, this may be a wasteful way of utilising such a valuable guano as fowl dung, but I have found in practice that the compost made in the way suggested retains quite enough ammonia for the usual run of culinary vegetables and fruit.

There are gardeners who object to using vegetable compost on the score that it is weedy and may be infected by the spores of disease. All I can say in regard to that is that I have found vegetable-mould prepared in the above manner a good deal less weedy than an average sample of cow or stable manure of the same age, or older. No attack of fungoid or other disease has ever been traced to this material during nearly thirty years use of it, but, needless to say, one would naturally be careful to avoid putting on the heap any vegetable matter known to be infected with a disease that would be likely to be troublesome. As for wireworm and other pests, the mould is always remarkably free from them, and this, I think, may in part be due to the salt and soot. J.

CHRYSANTHEMUMS

Potting the Rooted Cuttings.

WHEN the shows are held throughout the months of October and November, interest in these flowers is very keen, and many new cultivators are now, as a result of that interest, engaged in the work of propagation. Experienced cultivators know how important it is that the young plants be cared for with as close attention as that bestowed on the maturing specimens bearing handsome blooms. The beginner may not be as careful in this matter and so lose valuable time.

From Christmas onwards to March the inserted cuttings form roots rapidly and the early-rooted ones soon fill the tiny pots with roots. The first batch of young plants will now require re-potting. If they are allowed to remain too long in the small pots a check to growth results, the stems prematurely hardening, and this check is, frequently, the cause of thin stems just above soil level, the thinness being apparent throughout the summer months.

If eight to a dozen roots are observed round the small ball of soil it is time to shift the plants to larger pots, usually the 3in. and 3½in. ones being large enough.

At this first repotting the future form of the plant should be decided upon. If the plant is to bear three large blooms, one specimen in a 9in. pot—or of the strongest-growing sorts a 10in. pot—will be sufficient. If the plant is to be one bearing a single bloom, one plant will be sufficient for an 8in. pot, two plants for a 10in. one. In the latter case the two plants should be placed in the 3½in. pot now, and be transferred to larger pots without their roots being disturbed till the 10in. size is reached. I consider 7in. pots too small for single plants at the final potting, where cuttings are rooted before the middle or end of January. They are suitable for March-struck plants if good cultivation is the rule right through. Where plants are grown for decorative purposes, too, it is wise on the part of the cultivator to arrange for the number of plants for each pot now.

The compost should be carefully mixed—a few ingredients are only needed. The most suitable are fibrous turf about six months old, sweet leaf-soil a little more than half-decayed and some old mortar rubble. Loam two thirds, leaf-soil one third will answer, with one peck of mortar rubble to a bushel of the above combined parts. Mortar rubble is preferable to sand, but the latter should be used if the former is not available. The leaf-soil will supply all the nutriment needed at this stage without any manure. GEORGE GARNER.

CORRESPONDENCE

CRYPTOMERIA JAPONICA VAR. VILMORINIANA.

THIS interesting dwarf form I observed recently in the rock garden at Verrières le Buisson, near Paris. As a small specimen it was obtained in Japan by M. and Mme. Philippe de Vilmorin in 1903, and was planted by them at Verrières. It was obtained under the name of Juniperus japonica, and has been grown under that name ever since; but it is an undoubted form of Cryptomeria japonica. It is quite distinct from any other form and is a much smaller plant than var. Knightiana (syn. var. pygmæa, H.B. ex Knight). Its branches and branchlets are short, stiff and very crowded; its leaves are short, stout, recurved and very close together on the branchlets. It has been planted out over twenty years, and in that time has made a dense, globular bush about 2ft. high by as much through, its habit being very regular and compact. It will make an extremely valuable addition to the dwarf conifers on the rock garden, and as it is now being propagated, one may soon hope to be able to acquire it.—MURRAY HORNIBROOK.

FREESIAS SEEDING OUTDOORS.

I WOULD like to reply to the Rev. Jacob's query regarding Freesias growing and ripening their seed in the open garden (December 22, 1923, page 665). Freesias have been grown successfully here in the open at the foot of a greenhouse wall in a little soil in the gravel path. In the summer of 1922 the seed-pods were not picked off, and they ripened a heavy crop of seed (in 1923 they were picked off). Now, this year, all along the front of the plants are masses of seedling Freesias in the gravel path, some of them 30ins. away from the parent plants, the seed having no doubt been moved there when the gravel was raked over. The plants are not protected in any way, although the foliage is scarred a little this season by the 20° of frost which they withstood in November. The bulbs planted were just the small bulbs left over from potting. A small clump of Tritonias was tried last year in the same position and was quite a success.—E. HAYWARD, *High Hall Gardens, Wimborne.*

ROSCŒA CAUTLEOIDES.

I THINK one reason why this and other species of Roscœa are not so frequently seen in gardens, as "S. A." (page 10) reminds us they deserve to be, is that, after disappearing entirely in winter, they are very late in shewing above ground in the following year; wherefore, unless their position is distinctly and permanently labelled, the roots are most apt to be destroyed by hoe or fork. Of the five species which we have found to be quite hardy here, RR. Humeana and purpurea are generally visible by the end of April, the former flowering in June, the latter towards the end of July. R. cautleoides also flowers in June, but gives no sign of its presence till near the end of May; while July is nearly sped before shoots of R. capitata pierce the soil, only a week or ten days before it opens its fine violet blossoms at a height of 16ins. or 18ins. The variety named by Bees "August Beauty" behaves in a similar way. I do not know whether it is a distinct species; to all intent it is a late-flowering replica of R. cautleoides, but whereas that species grows in a compact clump, both R. capitata and August Beauty send out wandering roots and soon cover a considerable space.—HERBERT MAXWELL, *Monreith.*

EUCRYPHIA PINNATIFOLIA.

AS we are large growers of this plant, we are particularly interested in "Formakin's" letter in your last issue. We wonder if "Formakin" or any of your readers has ever noticed how many distinct forms there are in the plant under this name. Some types are much superior to others both as regards growth and quality of flower. Our best form makes growth of over 12ins. each year, and we get cuttings that root quite freely; other forms only make stunted growths, and it is difficult to find a suitable cutting and even more difficult to root it. The flowers of the better form are much larger and the trusses of blooms more than double the size of those of the inferior types; the anthers of our best form are quite a good crimson, while most of the others pass from yellow to brown and are not nearly so effective. We must say our experience of transplanting has been very different from that of "Formakin." We transplant our stock every second year, and never lose a plant. We also send away many plants each year, some over 6ft. tall, and have never received a complaint from any customer. The trade always take about 200 annually in 2ft. to 4ft. stuff, and if they did not have success they would certainly not come for them year after year. After reading "Formakin's" note, I at once went out and had two plants each 10ft. high removed, and have every faith in their success. Our best plant was put in twelve years ago and was then 4ft. high; to-day when measured it was exactly 16ft. 6ins. and in perfect health. From this plant we cut branches 8ft. long for a show last August, and each year it gets heavily cut for exhibiting purposes. Another plant put in at the same time and within 8yds. of the above has only made 8ft. of growth in the twelve years, and gives very few cuttings; in bulk it is not a quarter of its companion. The idea of planting Ericas at the root seems pretty general, and is even mentioned in Mr. Bean's book, "Trees and Shrubs Hardy in the British Isles," but we cannot agree with it all the same. Eucryphia pinnatifolia is a surface-rooting plant, and if Ericas were planted on it they would take all the surface moisture that came their way and rob the plant of its chief feeding ground. We consider a good mulching, which can be removed occasionally for hoeing, much better. It might interest some of your readers to know that on one occasion we broke up seventy large bushy plants into 600 pieces, and they all made fine saleable plants two years after, and on another occasion we cut large bushes into three and four pieces with a saw. Some of these pieces are fine specimens now; others were sold.—W. SLINGER (The Donard Nursery Company).

THE IMMENSE-FOLIAGED GUNNERA MANICATA.

THE GIANT GUNNERA.

I DO not know whether the enclosed photograph of Gunnera manicata may interest you, or whether it is worth reproducing in THE GARDEN.—R. HAGUE, *Osmington, Weymouth.*

[The picture well shews the stature of the species, for which, unfortunately, G. scabra too commonly deputises in gardens.—ED.]

THE GENUS ALLIUM

MAY I supplement the list of species described in "W.I.'s" interesting notice of this genus (pages 4 and 5) by adding three others which deserve attention. Allium sphærocephalum from Eastern Europe never fails to attract the attention of visitors by its globular heads of rich reddish purple, borne 2ft. high on thin wiry stems that no gale prevails to break or bruise. "The Hatpin Plant," my young people call it, from its resemblance to giant hatpins stuck into the ground. A. subhirsutum, from Southern Europe, bears abundance of clear white flowers in umbels in early summer. It spreads freely if allowed liberty, but is easily kept in check, and its slender grass-like leaves do not interfere with its neighbours. A third species landed here two or three years ago under the name of A. Beesianum, and has proved itself desirable. It carries heads of pendent light blue flowers on stiff stems 8ins. or 10ins. high.—HERBERT MAXWELL, *Monreith.*

SAXIFRAGA GUTHRIEANA.

ALTHOUGH I have known Saxifraga Guthrieana for very many years, I have never been able to ascertain with whom it first originated, and it is

Digitized by Google

only recently that I have learned that its parentage is said to be between SS. Andrewsii and Aizoon. The former is itself a plant of hybrid origin, and there is a marked resemblance between it and S. Guthrieana, although the latter is smaller and not nearly so vigorous in growth. Indeed, some people find a difficulty in retaining it in their gardens. It is quite a good plant, although too much resembling the London Pride section of the genus to be as popular as some encrusted or Kabschia kinds. It has, however, a variegated-leaved variety, called S. Guthricana variegata, which is a great beauty. None of the other variegated-leaved Saxifrages, of which there are a few, can rival it in beauty of variegation. The pretty leaves are a wonderful combination of green, white, yellow and pink. It is now, I think, very rare, but has always been difficult to keep in the garden. Probably the paucity of chlorophyll in the foliage makes it more delicate, but, in addition to its inclination to be "miffy," it seems to be attractive to the birds, as from time to time I have found that feathered enemies were at work tearing up the rosettes. This happened in spring and was, I believe, due to the desire of the birds to employ the rosettes for nesting purposes, as they sometimes take other Saxifrage foliage for this. The green-leaved form is of no special value, but the variegated one certainly is, and those who are so fortunate as to possess it should take care of their plants.—S. ARNOTT.

CLIMBING FRENCH BEANS.

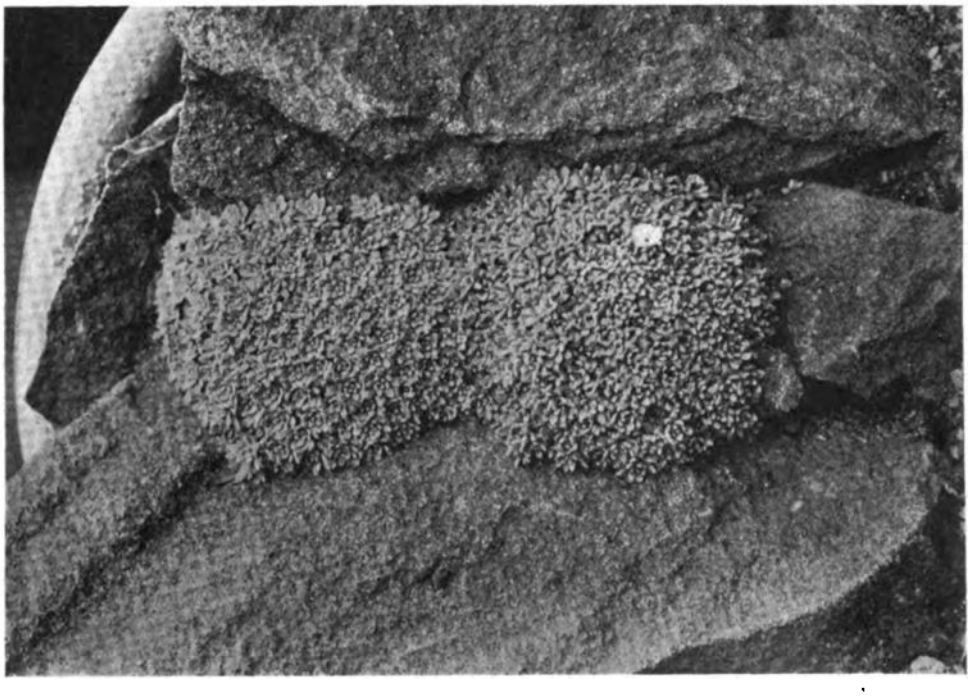
THESE have proved to be of great utility to us for several years past, both for indoor and outside culture. We commence in the early days of the year with a sowing in pots, the produce of which is subsequently planted out in a bed of soil against the back wall of a forcing-house, where the plants have a space about 8ft. high to grow on. The plants grow away quickly, and as regards cropping are but little behind the earliest section of dwarfs sown at the same time. They are, of course, much more prolific and continue in bearing longer than the latter. A little time later another sowing is made in 6in. pots. Not more than two plants are retained in each pot, and the pots are ultimately turned out against the back wall of a lean-to vinery. This sowing is timed to be ready for planting out at the time the Vines are started, which gives the Beans a good start before the Vine leaves form a canopy overhead. This formation of the canopy is, moreover, deferred by the method adopted of training the Vines. Instead of tying the Vines direct to the wires, which are about a foot from the glass, the rods are suspended in V-shaped slings at about 6ins. below the wires. This arrangement does away with the frequent tying down necessitated when the rods are nearer the glass. The shoots may, in fact, be allowed to grow on till flowering is over with a minimum of attention in this respect, and with no detriment to the Vines themselves. It is surprising, however, how well the Beans crop when the shading by the Vine foliage is complete; one can often pick them within a foot of the ground. Of course, such a plant as Phaseolus multiflorus must in its habitat produce fruit under and among the leaves of the shrubs or trees to which it attaches itself. The length of the two glasshouses above mentioned is 20ft. each, and from the two plantings of Beans we get a continuous supply for weeks. For the later supply of French Beans outdoors they are valuable also, comparing not unfavourably with the ordinary Runners for fertility and continuity of bearing when grown under similar conditions. The variety which we have found to be most useful for inside culture is Carter's Re-Selected Climbing French Bean. This sort is not so rampant a grower as Tender and True, which is a very good one, but which makes an extraordinary amount of growth when grown in heat.—R. DEAN, *Basingstoke.*

THE USE OF THE POLYANTHUS.

MY experience is much the same as that of "N. H. P." (THE GARDEN, December 29 last, page 678) with respect to Polyanthuses in the grass or wild garden. Some years ago I planted a considerable quantity of bulbs and plants in the grass of a lawn under some ancient Acacias to form a permanent semi-wild garden. I put in Daffodils and Narcissi in many varieties, Grape Hyacinths, Crocuses, Fritillarias, Scillas, Erythroniums, etc., and having a quantity of Polyanthus plants to spare, planted them here and there in bold clumps. At the time of flowering the bulbs gave a beautiful display, but the Polyanthuses seemed out of place—as Mark Twain's panorama man said of the piano accompaniments, "they didn't seem to gibe with the general gait of the picture." Their colours seemed out of harmony with the yellows, whites and blues of the rest, and they reminded one of spring gardening in the formal beds. However, when the bulb foliage had all withered, the Pennsylvania mower went over the ground weekly and the Polyanthuses disappeared. Looking over this site last spring, some ten years after planting, I found the Daffodils had done well in most cases, forming colonies and blooming profusely, but the Sulphur and Orange Phœnix, and the Polyanthus varieties Grand Monarque and Soleil d'Or were all gone and had not been seen for years, the Muscari had held on but had not multiplied much, and a few Snake's-head Fritillaries still lingered, while on a raised knoll some dainty little Dog's-tooth Violets were shewing their pretty marbled leaves, with Scilla sibirica keeping them company; but the real tenants of the land were the Daffodils, and Narcissi—Emperor, Empress, Horsfieldi, Golden Spur, Princeps, Figaro, Von Sion, Barrii and Poeticus were holding their own with breadths of Crocuses, yellow, purple and white. These are the really satisfactory bulbs to plant in the grass and wild woodland; so many of the other plants we try are, if I may use "N. H. P.'s" good phrase, "too sophisticated."—J. P., *Glos.*

ANDROSACE IMBRICATA.

I WONDER if the enclosed photograph of Androsace imbricata will interest your contributor "Ithaw." The photograph was taken on January 3 and is seven-eighths full size. The two plants are three year old seedlings and are descendants from plants collected in 1914 in Canton Valais. They have had alpine-house culture. I find that A. imbricata flowers freely; the flowers are as large as those of A. carnea and of the purest white. Good seed sets every year, last year's seedlings each consisting now of about half a dozen rosettes. The plants photographed are just coming into flower, being well set with buds. They will be at their best in May. The pans are kept quite dry during the winter and are laid on their sides.—M. W. JENKIN, *Trimmers Field, Hindhead.*



TWO HEALTHY PLANTS OF THE DIFFICULT ANDROSACE IMBRICATA.

VARIETIES OF SWEET PEA SUITABLE FOR AMATEUR GROWERS.

THE time will soon be here when growers of this favourite flower will be ordering their seeds for next summer's display. As the majority of lists are rather confusing owing to so many varieties being much alike, I thought it might be of interest to mention a few which I consider to be the best of their respective colours, good doers and equally suitable for exhibition or house decoration. I do not intend to deal with their culture, but before sowing, whether in pots or in the open ground, I strongly recommend that all black-seeded varieties should be chipped, that is, the outside skin, or husk, should be broken with a sharp knife. This gives an even germination and ensures much better results. The following is my list of twelve distinct varieties:

Edna May Improved, white.
Austin Frederick Improved, lavender.
Elegance Improved, lilac pink.
Hilda, deep orange, shaded pink.
Maroon King, dark maroon.

Digitized by Google

Royal Scot, a grand scarlet.
Charity, crimson.
Hawlmark Pink Improved, richest coloured pink to date.
Mrs. Tom Jones, blue.
Royal Purple, the name describes the colour.
Sunset, bright rose.
Jean Ireland Improved, the best Picotee.
The above varieties are perfectly sunproof and require no shading.—ALFRED GURR, *Walmer*.
[Possibly other readers would care to give their views as to the best twelve varieties?—ED.]

THE TREATMENT AND PLANTING OF DRY BANKS.—II

Some Non-Shrubby Plants

WHEN dealing in a previous article with shrubs for the furnishing of dry, sun-beaten banks, I pointed out that it was a matter of the first importance to get the surface of the soil well covered, since this does so much for the conservation of moisture. Now, on coming to speak of herbaceous and other non-shrubby plants, the same rule holds good. Whether one's plants are put in along with shrubs or grouped alone, as they would be in an ordinary border, one's first object should be to cover the soil. But, since this takes time, even when quick-growing, creeping kinds are mainly chosen, recourse may have to be made to the temporary use of annuals, which, if carefully selected, will achieve all that is wanted and prove helpful rather than inimical to the progress of the more permanent things.

There is such a vast choice of kinds for dry banks, and the latter present such infinite degrees of dryness and other diversities, that each one must exercise some discretion in his selection of plants for his own particular use. I am referring here mainly to exceedingly porous gritty soils, often very abruptly sloped, which, for various fairly obvious reasons, have to be planted with the view to their lasting as long as possible with a minimum of attention. In that respect they are totally different from the border, which admits of a frequent lifting of plants, periodical manuring, staking and so forth. Many perennials, even though good dry-soil plants, are, therefore, omitted which might in other circumstances have been included; biennials are ruled out altogether save where they will produce self-sown seedlings, and the following paragraphs do not include such alpines as are generally considered fastidious.

If there is a general rule that may be fairly safely relied upon in such matters as these, it is that the great majority of grey-leaved plants are sun-lovers and good for poor, dry places. These include the Alyssums, of which the old A. saxatile is still perhaps the best, though its variety citrinum, with flowers of a soft lemon yellow, is equally charming in its own way. A spinosum (now among the Ptilotrichums) is a delightful grey-leaved little bush of about 5ins., well protected by a multitude of tiny spines. No place can be too hot and dry for this, and its variety roseum, in which the white flowers of the type are flushed with pink, is even more attractive. A pretty companion for this might be A. Idaeum or A. Moellendorffianum, silvery, slender trailers which have proved quite reliable with us.

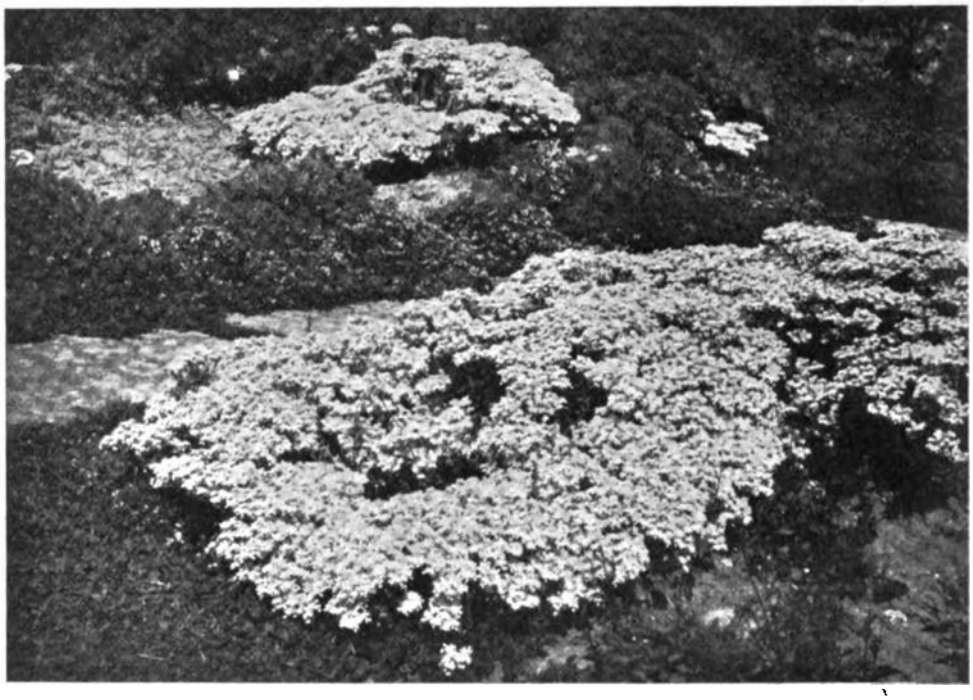
Pterocephalus Parnassi is a grey carpeter that will cover a considerable space, and its large, short-legged flowers—like pink Scabiouses—are very cheerful in the late summer. Some of the stronger-growing Antennarias will group well with the above in the poorest of soils, where a soft blend of grey, white and pink is appreciated, and along with the above and other things we have masses of Veronica pectinata, Æthionema iberideum, Prickly Thrifts (Acantholimum), Achillea serbica and tomentosa, Gypsophila repens and, where it will not get overgrown by bigger things, the dainty G. cerastioides.

The Acænas are first-rate plants for quickly covering a dry, stony place with a dense carpet of green, silvery or bronze foliage. Indeed, I know of no other plants which will do what is expected of them in this way in so short a time. We all have our own tastes in such matters, my own preference in Acænas leaning to glabra, Buchanani and microphylla. Anything put near these New Zealand Burrs must be a hearty doer. They are generally best left in entire possession of the spot they are intended to cover. But such as the stronger Cerastiums, the various forms of Iberis sempervirens, Catmint (Nepeta) in groups, Santolina and clumps of the bolder kinds of Anthemis (Cupaniana, Aizoon and tinctoria) will generally hold their own among the dense and wiry mats of the Burrs.

Saponaria ocymoides is an ideal plant for thirsty, sun-beaten slopes, making fine masses of rosy crimson in the later summer, and there is also a good white. For the rougher parts, or a "seat in the gallery," S. officinalis—the only double wild flower I know—is not to be passed over too lightly. This is a robust spreader, and spreading may be as useful in one spot as it is noxious in another; the tall-stemmed flowers are a fresh rose pink. Silene maritima fl. pl. may also be included in this company. It is not a choice plant, yet its blue-grey cushions of foliage and white flowers, like those of some degenerate Mrs. Sinkins Pink, are useful enough in places where few better things would grow. Then there is S. Schafta, an admirable late summer bloomer, and the dainty alpestris, both double and single, is one of the gems of its race. But it is not seemly to take advantage of the sweet temper of this choice little thing by putting it in too poor a place.

Waldsteinia trifolia has rapidly made carpets of bronzy green foliage under most trying conditions here, and its yellow flowers are by no means unattractive. In the same genus are one or two more which, though hardly so pretty, are excellent ground coverers, and near to the Waldsteinias come the Potentillas, some of which are no less useful in the same way. P. alba is one of these, a drought resister of the best—once it has got established. But not less notable in that respect is the tall and elegant P. rupestris with its branching sprays of blossoms, the latter like those of the Grass of Parnassus. The dwarf form of this is a delightful little plant.

Geranium sanguineum in any of its various forms (including the gorgeous nepalense of the lists) will adorn the most sterile of sunny banks with its brilliant colour, sowing its own seed. Nor have I ever known a soil too bad or too dry for the hybrid progeny, innumerable and pink, with which GG. Endressi and striatum people the world about them, and this twain need no encouragement for them to indulge in these extravagant flights of colonisation. G. nodosum is another of the race that never flinches with us under the worst of conditions, and it seeds itself as freely as sanguineum. All the Linums are first-rate for the purpose under discussion. Jasione humilis is equally indifferent to drought and starvation, while among the pea-flowered tribe are such useful plants as Hippocrepis comosa, Lotus corniculatus fl. pl., the sub-shrubby Rest-Harrows (Ononis) and the closely allied tribes of Orobus and Lathyrus. L. tuberosus deserves special mention as a dry soil plant which will soon cover a wide space, making large, tendril-bound clumps of a pleasing green, which it will adorn with a long succession of its rose pink, fragrant blossoms. This, however, is a species to be placed with



NO SITE CAN BE TOO DRY FOR THE BEAUTIFUL SEDUM ALBUM.

Digitized by Google

discretion, since it is an irrepressible spreader in a warm, free soil.

The Labiates offer so wide a choice of suitable plants for the driest of dry places that one cannot do more than mention the Thymes, more especially the creeping kinds, Calamintha alpina and grandiflora, the Skull-Caps (Scutellaria), Stachys corsica and lanata, Teucrium Chamædrys and aureum, Prunella grandiflora, Marrubium velutinum, the Lamiums and Origanum pulchellum.

Sedums and Sempervivums are also practically all lovers of sun and dry, gravelly soils, and the former afford us, among innumerable others, such first-rate carpeters as SS. spurium and oreganum, album and reflexum, the two last covering the most sterile of ground in an astonishingly short time. Choicer species there are, of course, in plenty, but the above we have found the most indestructible of their kind. When the climate will allow, the Mesembryanthemums should not be overlooked as suitable for grouping with the above. Few plants will give a brighter display of colour in the most droughty of circumstances.

The larger Sedums of the spectabile set and others will group with such sun-worshippers as Inulas and Hawkweeds (Hieracium), dwarf Golden Rods (Solidago), Onosma tauricum, Heuchera, Tellima, Erysimum linifolium, Artemisia stellariana and A. rupestris, and the stronger Achilleas. Helichrysum lithospermifolium is an attractive, white-leaved sub-shrubby plant with bold heads of yellow that does well with us on sun-burned banks. H. bellidioides is well known as a handsome carpeter and a pestilent weed, but it does not take so rapidly to what our most sun-parched places have to offer it as the trailing and pretty H. trinerve.

The Spur Valerian (Centranthus rubra) is a grand old plant for dry, rocky slopes where it is well away from mischief, the raspberry red (not the pucy crimson) variety making a wonderful all-summer show which is none the worse for a little of the white grouped in with it. The Centaureas offer several species which serve excellently for our purpose here, the several varieties of C. montana and the taller, golden-headed C. macrocephala being the most reliable. The Sea Hollies (Eryngium) all delight in a dry, stony root-run and as much sun as they can get, and conditions would have to be bad indeed to break the spirit of such lusty growers as the Globe Thistles (Echinops), the great Plume Poppy (Bocconia cordata), our beautiful pink Musk Mallow (Malva moschata) with its white form and M. Alcea.

Though fully alive to the value of many good dry-bank plants which have been omitted, I must conclude with a mention of Tropæolum polyphyllum and a regret that this fine plant should now be so difficult to obtain. Elegant in growth, beautiful in foliage and flower, T. polyphyllum might adorn many an arid slope. But the probability is that it often fails to give satisfaction owing to the tubers not being planted deep enough, this leading to loss in winter, to insufficient moisture during the growing periods and other troubles. If the soil is hot and stony, 1ft. is not too deep for planting, and once established the plants should be left alone for ever. A. T. J.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—Where it is necessary to keep up a good supply of vegetables and as much variety as possible, early Cauliflowers are an important crop. Plants in cold frames should have the lights removed on every favourable opportunity, the object being to keep them hard and sturdy. To maintain a succession, seeds should be sown of such varieties as Early London and Magnum Bonum. They may be sown in boxes containing light soil or even in a cold frame; in any case they should not be subjected to heat. Slow, short-jointed growth should be encouraged. When the seedlings are large enough to handle, prick them off in a cold frame and transfer them to their final quarters in March or April. Choose a rich piece of ground for this purpose.

Cabbages.—The plants that were put out in the early autumn are not looking too well and there are many blanks. The latter may be filled up at any time when the weather is favourable, and, should the soil become dry enough, ply the hoe between the rows.

Turnips, Carrots and Radishes may be raised on a hot-bed. Where sufficient long manure and leaves are available a hot-bed should be made, and when the rank heat has escaped, a few inches of light soil may be placed over the surface. A frame is necessary, and the bed should be 2ft. or so each way larger than the frame. The heat should only be moderate, just enough to germinate the seeds. Due attention should be paid to ventilation and watering, or the young plants will damp off. Do not sow the seeds too thickly, and the Turnips will require thinning to a few inches apart directly they are large enough to handle.

Mustard and Cress.—These are useful and easily-grown saladings, and to keep up a supply a small quantity may be sown weekly in boxes of any light soil and placed in a warm greenhouse or pit.

The Flower Garden.

Hollyhocks.—These stately plants are well adapted for planting in the shrubbery border and similar positions, and if seeds were not sown last year in the open ground, they may now be taken in hand. The seeds should be sown in well drained pans containing light soil with plenty of sand but not much leaf-mould added. Place the pans in a warm greenhouse until the seeds have germinated. Pot off the seedlings when large enough, and gradually harden them until they can safely occupy a cold frame. They may be transferred to their flowering positions about April.

Gilia coronopifolia.—This striking plant with its brilliant crimson-scarlet flowers is a half-hardy biennial, and seeds are often sown in August to produce a display the following year. It also succeeds if treated as a half-hardy annual, the seeds being sown now in gentle heat. A little care is needed or many of the seedlings will damp off, but the failures are not so numerous as when sown in August. Pot off the seedlings singly when they are large enough and plant out in May.

Salvias.—The various forms of S. splendens, such as Fireball and Glory of Zurich, employed for bedding purposes are often increased by means of cuttings, but they can also be raised from seed. An early sowing will provide plants that will furnish a fine display in August or even earlier. It is important that the seedlings be potted on as they fill their receptacles with roots, because starved examples take a long time to recover.

Fruits Under Glass.

Vines.—In many instances Black Hamburgh Grapes will have been started into growth, and the temperature should be from 55° to 60°, according to the weather, but when the Vines are in flower a night temperature of 60° should be maintained. All surplus bunches ought to be removed at an early date, and the ends of the shoots tied down to prevent them coming in contact with the roof glass. Stop each shoot at the second joint beyond the bunch of fruit, and retain enough growth to furnish the roof with strong, healthy leaves. To promote atmospheric moisture the walls and paths should be moistened with water, but how often will depend upon the weather. The roots should not become dry, and tepid rain water should be used.

Muscats.—Now is a good time to start the first house of Muscat of Alexandria Grapes to furnish bunches of ripe fruit about July. The house should be closed and the night temperature kept at about 45°. An effort should be made to get the rods to break into down growth evenly, and this can be done by bending the top part of the rod, which will cause the lower buds to grow.

The Hardy Fruit Garden.

Cleansing the Trees.—The winter spraying of fruit trees should be done before the buds begin to expand, and although the middle of February is considered the best time, there is no reason why such work should not be accomplished directly the pruning is finished. By spraying with a solution of caustic alkali a large number of insect pests will be destroyed, all lichen and mossy growths will disappear, and the bark will be cleansed. If a large number of trees need treatment, a sprayer should be used, but for a few specimens the syringe will suffice. Every portion of the tree should be wetted and a fine still day chosen for the operation. Gloves and an old suit of clothes should be worn, and care taken of the eyes, as the insecticide has a burning effect upon the operator.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Early Peas.—In the milder districts a sowing may now be made on a south border. Only a strip of ground where each line is to go need be forked over at present. Unless the soil is a light one, a deep drill should be drawn with the draw hoe and filled up level with old potting soil. A drill of the ordinary depth—about 3ins.—should then be drawn and the seed sown therein. Among numerous early varieties Ringleader and William Hurst are to be recommended. In less-favoured localities a moderate sowing may be made on strips of inverted turf in a greenhouse temperature and transferred to a south border later on. Wherever sown, two or three mousetraps should be set beside the crop, as, food being scarce at this season, mice are sure to appear.

Broad Beans.—In favoured localities a small sowing of Early Mazagan may be made on a south border, following the directions given above for early Peas. Allow 2½ft. between the lines.

Vegetables Under Glass.

Rhubarb.—Another batch should be introduced into a gentle heat, and as the sap is now on the move very little forcing will be necessary.

Seakale.—Introduce another small batch of crowns into heat. Seakale should not be forced hard and, as the season advances, still less heat is necessary. A moderately moist soil with the exclusion of air and light are the requisite conditions for producing pure white, tender and crisp crowns.

Lettuces.—A small sowing should be made in gentle heat of such early varieties as Tom Thumb and Early Ohio. When large enough to handle, this batch should be pricked out into boxes and in due course transferred to a cold frame, from which they should be cut later on. Lettuces and Endive now in frames should be lightly dusted with soot if slugs threaten. Prick the soil between the plants and fully expose them on all favourable occasions.

The Hardy Fruit Garden.

General Work.—Pruning, nailing and tying should be completed as soon as possible. Planting may still be undertaken with every chance of success. Pruning and training finished, the soil should be forked over to a depth of 6ins. or 8ins. for 3ft. or 4ft. round the stem of each tree, and then a mulch of half-decayed farmyard manure applied. By this means the roots are induced to remain near the surface and there assume the fibrous form, a necessary condition of liberal fruit bearing. It is when bare tap roots penetrate into the subsoil and from thence pump up water, resulting in the formation of a superabundance of vigorous soft shoots devoid of fruit-buds that failures occur. See that there is a sufficient stock of supports in good order for supporting the nets for Strawberries when the season comes round. On wet or stormy days repair all fruit nets. Look over Strawberry runners in nursery lines and tread the soil firm if it has been loosened by frost. Overhaul the fruit remaining in the fruit-room and remove any decaying specimens and pick out and use any fruits which are inclined to shrivel. Ventilate the room freely when a really fine day occurs, but keep close during frost or fog.

LIMESTONE

ROCK GARDENS built of local stone are often lacking in effect due to the stone rather than the building. It is only necessary to see our weathered limestone collected on the Fells to realise its beautiful effect. Each stone is a rock garden in itself.

We have the sole agency for the surface stone of a large estate in Westmorland and will load in trucks at 25/- per ton. Six tons will make quite a fair sized rock garden. We shall be pleased to help with advice and plants, now is the time to build.

The Flower Garden.

Sweet Peas.—In order to be able to cut Sweet Peas at the end of June or the beginning of July the seeds should be sown within the next fortnight. The most convenient method is to sow in ordinary propagating boxes filled with a mixture of three-quarters loam and one quarter of clean sand. It is not advisable to use leaf-mould. Draw drills not more than 1in. deep and 2ins. apart, place the seeds about 1in. apart in the drills, and level the entire surface. Place the boxes in a vinery or peach-house, where the canes have been started into growth, until germination takes place, but transfer to a cold frame before the seedlings exceed 1in. in height.

Eremurus robustus.—This noble flower is a rival even to Lilium giganteum, attaining as it does a height of from 6ft. to 8ft., surmounted by a scape of pleasing pink blossoms. Planting may be carried out any time now if weather permits, and the plants should never be disturbed as long as they thrive and flower satisfactorily. This plant requires a deeply cultivated, rich, well drained soil for its perfect development.

Camassias.—These attractive North American bulbous plants are barely hardy, but will succeed out of doors in the milder districts in light, well drained soil. They should be given protection by covering them with ripened stems of herbaceous flowers or other dry, loose materials. The bulbs may be planted within the next fortnight from 4ins. to 6ins. deep in light soil. Protect for some weeks as indicated above. C. esculenta and its varieties alba and atro-cœrulea are all worthy of a place, so is C. Leichtlinii with its varieties alba and cœrulea.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Seed-Sowing.—The propagation of plants from seed plays such an important part in most gardens that a few hints on the essentials of successful seed-raising may not be out of place at this, the beginning of the season. The three essentials for successful germination are heat, air and moisture. Most cultivators are fully aware of the importance of heat and moisture, but many, I feel sure, fail to recognise the importance of soil aeration, not only as regards seeds, but also to the rooting of cuttings. For this reason composts for seed-sowing should be light and open in composition. In sowing seeds indoors this condition is generally best obtained by mixing leaf-soil and clean sharp sand with loam; ample drainage in the seed pots or pans is also important. When filling the pots or pans the soil should be in good working condition, because if too wet there is a danger of the soil being made too close and firm. On the other hand, if too dry it is impossible to make it firm enough, and a moderately firm seed-bed is essential for successful germination. The fineness of the soil will depend on the size of the seeds to be sown. Very fine seeds, like those of Begonias, Calceolarias and Rhododendrons, should be sown on the surface and should not be covered at all. The seed-pans for fine seeds should be prepared and thoroughly watered several hours before sowing. After sowing, they should be covered with pieces of glass and shaded; thus in most cases little or no watering should be required until germination takes place. If water is required in the case of fine seeds, the pots should not be rosed, but stood in a vessel of water, thus watering them by sub-irrigation. Darkness is generally supposed to assist germination, but it has been proved that darkness in itself has no effect; but what is important, is the fact that when we shade or cover seed-pans it prevents evaporation and thus to a great extent does away with the need of frequent watering until germination takes place. I have for long suspected that many failures with seed germination are due to too deep covering, and have recently proved that such is the case, as fairly large seeds just covered germinated better and quicker than when covered the regulation depth; this, of course, proves the importance of aeration.

Annuals for the Greenhouse.—Either hardy or half-hardy annuals at the present day play an important part in the furnishing of the conservatory and greenhouse. They are best sown during September, but where for any reason this was not done they may be sown at this time and quite useful plants produced, Schizanthuses, Clarkias, Godetias, Mignonette, Collinsia bicolor, Lobelia tenuior, etc., all being very suitable. The seed should be sown thinly, the young plants pricked off early before being crowded in the seed-pots. Annuals of this description should never suffer from any check, and should at all times be grown under cool, airy conditions, and watering should be carefully done. Annuals sown during September will now require a shift into larger-sized pots. In most cases they are best flowered in 6in. or 7in. pots. The plants should be kept neatly staked and tied as occasion requires

Gloxinias are very useful for furnishing the greenhouse during the summer months, the first display being obtained from dry tubers raised from seed last year. Where an early display is required, a quantity of tubers should be started some time this month. They should be laid out in boxes of leaf-soil and sand in a warm house until they start into growth, afterwards putting them into suitable-sized pots, using a light rich compost for potting. Seed should also be sown some time this month. The resulting plants if grown steadily on, will flower towards the end of summer, and should make good tubers for next year.

Streptocarpuses are equally useful for the greenhouse. Young plants raised from seed last year that have come safely through the winter should now be shaken out of their pots and be repotted into a light rich compost, growing them in a house with a temperature of 55° to 60°. They should be potted on as they require it, their final shift being into 6in. pots. As the season advances and they approach the flowering stage they should gradually be given cooler cultural conditions. Seed should also be sown some time this month. The young plants if well grown during the summer will give a good display towards the end of summer.

Forcing Plants.—Continue to introduce bulbs and other plants used for this purpose into a warm house according to requirements.

Royal Botanic Gardens, Kew. J. COUTTS.

Muehlenbeckia axillaris.—Often listed as M. nana, this is one of the dwarfest of rock garden shrubs, making a mat of thin, wiry stems no more than 1in. or 2ins. in height. It is a deciduous species from the mountains of New Zealand, and quite hardy, delighting in a ledge of light soil either in full sun or partial shade. The leaves are very minute—in proportion to the size of the plant—and the flowers, borne in summer, almost invisible. These are followed by tiny, glassy berries which might easily be mistaken for beads of dew. M. axillaris is an interesting little shrub for parts of the rock garden devoted to very dwarf plants, and it is of the easiest culture. It often berries far more freely than the much larger and better-known species.

Royal Horticultural Society's Journal.—The Secretary of the Royal Horticultural Society would be very grateful to any readers of this paper who would be kind enough to send him any surplus copies of Part 1 of Volume 48 of the Royal Horticultural Society's Journal dated January, 1923. The stock of this Journal has been entirely exhausted, and the Society is unable to send copies to Fellows who have lost their own and who have written asking if fresh ones could be spared.

Trials at Wisley, 1924.—The Royal Horticultural Society will carry out, during the coming year, trials of the following annual flowers and vegetables. Varieties for trial should reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before January 31, 1924. Parcels should be sent, addressed as above, to Horsley Station, Southern Railway. Forms of entry, one for each variety sent, may be obtained on application to the Director. Annual Scabious (one packet of each variety). Sweet Peas, *excluding* those of the following colourings: Blue, lavender, lilac, mauve, purple, rose, salmon, carmine, cerise, all pink shades, orange and scarlet. (The exclusion covers bicolors, picotees, flushed and flaked varieties as well as self-colours.) Fifty seeds of each variety. Dwarf Beans, quarter-pint of each variety. Endives, one packet of each variety. Cos Lettuces one packet of each variety. Potatoes early kinds only, forty-eight tubers of each variety.

ANSWERS TO CORRESPONDENTS

FRUIT GARDEN.

JEFFERSON PLUM ATTACKED (Mrs. R. H., Dorset).—The Plum is affected by gumming and attacked by the brown rot fungus. Both have probably originated from wounds. Plum pruning should be kept at a minimum. Spray the tree with Bordeaux mixture at the end of March and again after the petals fall. Avoid all tendency to coarse growth. There is nothing amiss with the Apples.

TREES AND SHRUBS.

SHRUBS FOR EAST BORDER AND WALL (E. H.).—Cotoneasters would be very suitable for the wall, the best being CC. microphylla, buxifolia, rotundifolia, salicifolia, horizontalis and frigida. The Berberis family should do well, especially the newer Chinese species, BB. Wilsonæ, aggregata, polyantha, yunnanensis and the Wisley hybrids. Berberis Aquifolium and BB. stenophylla Irwinii, verruculosa and buxifolia nana are good and suitable evergreen kinds. Other suitable plants would be Aucuba japonica nana rotundifolia, Buxus myrtifolia, Hypericum calycinum, Cornus alba Spathii, Genista hispanica, Philadelphus Lemoinei erectus and P. microphyllus and Tamarix pentandra (Pallasii rosea). Good climbers for the wall are Hydrangea scandens, Vitis Coignetiæ, V. inconstans (Ampelopsis Veitchii), Clematis Jackmanni, C. Flammula, Jasminum nudiflorum, Rose Gloire de Dijon and any of the strong-growing Ivies.

ROCK GARDEN.

STONE FOR THE MORAINE (E. C. T.-P.).—Either Kentish ragstone or Bethersden marble may be used for making a moraine. There may be a very slight advantage in using Kentish ragstone (especially if the upper layer, called in some quarries "toppings") is used, because the process of disintegration is a little more rapid than is the case with Bethersden marble. This imparts a grittiness to the soil that most alpine plants enjoy. Bethersden marble may be worn down by friction to a polished surface, but atmosphere and water scarcely affect it. No stone of this nature offers any attraction to vegetation. Neither of them contains lime in a condition to become soluble, and they are both perfectly safe for lime-hating plants. Nor will either contribute anything desirable for lime-loving vegetation. Therefore in using them it would be wise to add lime in some form for a colony of those plants that require it. Old mortar rubble is one good constituent, broken up Bath stone another, and this is sufficiently gritty to keep a fair proportion of lime. Chalk is unsightly, but is the most direct method of introducing lime into the soil. A mixture of these three added to about six or eight times the quantity of broken stone and light, rich soil is probably the ideal chemical compound for lime-loving moraine plants.

THE GREENHOUSE.

PRIMULAS AND CINERARIAS UNSATISFACTORY (F. E., near Worksop).—The plants have suffered from lack of water or from over-watering, or from too high a temperature for a time; the symptoms show only that the leaves have had insufficient water. Examination of the root may show this has suffered from being in a water-logged soil.

MISCELLANEOUS.

VARIOUS QUESTIONS (R. E., London).—Hardy perennials may be planted any time now; the sooner the better if the ground is in workable condition. It is certainly too late now to plant spring-flowering bulbs. Dahlia roots should be planted in May in the open. However, pot roots may be obtained now and placed in a greenhouse where frost can be excluded.

TO PRODUCE BLUE HYDRANGEA FLOWERS (Lady R.).—We presume our correspondent refers to Hydrangea hortensis. We have had no experience of the use of pounded slate in the soil. Iron filings, from a smithy or foundry, and alum mixed with the soil and, further, the applications of alum water in a weak state after the new growth is active, sometimes have the desired effect. All artificial means, however, give temporary results only, so that treatment should be annual. Of some scores of huge specimens, in a garden in the neighbourhood of the New Forest, ninety-five per cent bore deep blue flowers, and some were on low-lying and others on high ground. There was much peat and bog land in the district. The blue-flowered plants remained blue and the pink-flowered ones retained a good pink colouring.

NAME OF PLANT.—(C. M.).—Cyrtanthus lutescens.

GARDEN SEEDS AND POTATOES

Writing of our stands at the Glasgow Horticultural Society's Show last September, "Amateur Gardening" said:

"Messrs. Austin & McAslan were represented by one of the finest exhibitions in the show, the chief features being vegetables, gladioli and roses. This firm have become famous for their special strains of seeds and the examples staged fully justified the high praise bestowed. **Cauliflower: Austin's Improved Early London; Carrot: Austin's Exhibition Intermediate; Parsnips: Austin's Giant Exhibition (very fine this); Pea: Chancelot (very long pods); Beet: Austin's Acquisition** are well worth the attention of every exhibitor. Potatoes were also exhibited, Arran Comrade, Immune Ashleaf, Midlothian Early, Crusader, Ardneil Rose, Di Vernon and King Edward being in splendid condition. **The large gold medal awarded was well deserved."**

We shall be glad to send our illustrated catalogue free on request. Orders have prompt attention.

THE GARDEN

No. 2723.—Vol. LXXXVIII.] [January 26, 1924.

LITHOSPERMUMS AND ONOSMAS

These two genera are closely allied and belong to the Borage family. Lithospermum is known by the common names of "Gromwell" and "Stone-seed," the latter in allusion to the hard, stone-like character of the seeds. The genus Lithospermum is an extensive one, consisting of some forty or more species of usually hardy annual or perennial herbs, sub-shrubs or rarely small shrubs, widely spread over Europe and Northern Asia, although most of the species belong to the Mediterranean region. In colour the flowers of the different species vary from white to yellow and blue, the colour of the latter rivalling in beauty and intensity the blue colour of some of the Gentians. Only about a dozen species of this genus are worthy of cultivation, and these are valuable for the rock-garden or border. They thrive best in sunny positions, in sandy loam, which should have thorough drainage. Some are excellent wall plants, while others, like L. purpureo-cæruleum, are valuable for covering half-shady banks and slopes. This species prefers half-shade, but it will also grow in sunny places, providing the soil is moist. The sub-shrubby kinds are increased by means of cuttings, while all may be raised from seeds. The seeds, however, have a very hard shell, and take a long time to germinate. Some of the best kinds are:

L. canescens.—This North American species is a herbaceous perennial growing about 9ins. high, with erect stems divided into two leafy cymes at the top. The yellow flowers are produced in June and July. Like the other North American kinds, this is not easy to manage in this country, but is well worth a little trouble, as the yellow flowers are very attractive.

L. fruticosum.—This species is closely allied to the well known L. prostratum, but is more erect in habit, forming a small shrub over 1ft. in height. On the twiggy stems the narrow dark green leaves are produced in tuft-like bunches at the end of the branches. The small flowers of a good blue colour are borne at the tips of the branches in loose inflorescences from May onwards. A lover of limestone, this plant is a native of the Eastern Pyrenees and Southern France.

L. Gastoni.—One of the herbaceous perennial species, this beautiful plant, which is found in the Central Pyrenees, is rare and seldom seen in gardens. It has frequently been introduced into this country, but has not been satisfactorily established in many places. It grows about 1ft. high, with erect stems and dark green, hairy leaves, while the large flowers, produced in April and May, are of a soft deep blue, with purple buds. L. Gastoni grows best in half-shady positions, planted in a mixture of loam, peat and leaf-mould.

L. graminifolium (syn. Moltkia graminifolia).—This is a native of Italy, where it is said to cover extensive slopes with a beautiful carpet of azure blue flowers. It forms a dwarf shrubby plant with long, narrow, grass-like leaves, from which arise the flower-stems, some 6ins. long, bearing drooping clusters of flowers in June and July. It prefers a dry and sunny situation in limestone, and is a gem for the rock-garden, increasing in size from year to year. It is somewhat variable in habit, some forms being more shrub-like than others. L. intermedium and L. Frœbeli are supposed to be hybrids of this species and Moltkia petræa.

L. hirtum is a perennial from the Southern United States. It is of dwarf habit, and produces its rich orange yellow flowers in May. It is known as the "Hairy Puccoon," and is a handsome plant when well grown.

L. oleæfolium.—One of the dwarfest members of the genus, this is a native of the Eastern Pyrenees, growing in the crevices of rocks and stony places where its long stoloniferous growths soon cover wide spaces. The light blue flowers with pink buds are produced in small clusters in April and May. It may be treated as a wall plant and is easy to grow in a warm sunny position.

L. prostratum.—Few of the low-growing plants that we class as alpines are so beautiful or important in the rock-garden as this brilliant species. It spreads into wide sheets, even in the poorest soil, and is seen to perfection when crowning some rocky mound or ledge in full sunshine. The foliage is of a very dark green, often approaching bronze, while the rich gentian-blue flowers are very freely produced during the greater part of the summer months. For wall-gardening there is nothing better than this attractive dwarf shrub, its trailing habit with close carpet of evergreen leaves making it eminently suitable for furnishing such places. While L. fruticosum belongs to the Eastern Pyrenees, this species is confined to the western end of the same range. "Heavenly Blue," with

THE GOLDEN DROP, ONOSMA TAURICUM, IN A TERRACE WALL.

THE SOMEWHAT RARE LITHOSPERMUM PROSTRATUM ALBUM.

ONOSMA ALBO-ROSEUM HAS SILVER-GREY FOLIAGE.

soft but bright blue flowers, is a charming variety.

L. PURPUREO-CŒRULEUM.—This is a pretty perennial species of spreading habit, the trailing stems of which soon cover large areas, making it valuable for planting in places that need to be quickly furnished. The erect flower-stems reach a height of a foot and bear clusters of purplish blue flowers in early summer. This species is a native of Europe, and is also found in parts of this country. Closely allied to this is L. Zollingeri, a native of China and Japan. It has the same trailing habit, with broader leaves, and also bears purplish blue flowers.

L. ROSMARINIFOLIUM.—A small shrub about 6ins. high, from South Italy, this species requires a warm and well sheltered position, owing to its winter-flowering character. It bears, with great freedom in suitable places, deep blue flowers, which open from pink buds. It should do well in the gardens of the South, but is a failure in the Thames Valley.

There are many other members of this genus, including the yellow-flowered LL. angustifolium, and multiflorum, from North America; while closely allied is Moltkia petræa, a handsome, shrubby plant some 2ft. high, with twiggy branches, short green leaves and numerous rich violet blue flowers during the summer.

THE ONOSMAS.

The Golden Drops have their headquarters in South-eastern Europe and Asia Minor, but the species which is, perhaps, the most distinct of all, O. pyramidale, with scarlet or crimson flowers, is a native of the Himalayas. It is doubtful if this species is now in cultivation. Fifteen species are found in Europe, but probably not more than ten in all are grown in gardens. The Onosmas are all essentially plants for sunny places, and should be planted in poor stony soil with plenty of drainage. In rich ground they make luxuriant growth in summer, but are very liable to damp off during the winter. Most of them are easily cultivated and are readily raised from seed, but, as a rule, they dislike moving when they have attained a moderate size. It is, therefore, advisable to grow the seedlings on in small pots and plant them out when well rooted. One of the exceptions is the beautiful O. albo-roseum, which makes plenty of fibrous roots and may be transplanted with success if the work is carefully done. Of those in cultivation the following are the most distinct and well worth growing:

O. ALBO-ROSEUM.—This species, a native of the mountains of Asia Minor, is of spreading, sub-shrubby habit, and forms, in cultivation, a cushion-like plant under 6ins. high. The evergreen silver-grey leaves are covered entirely with stiff bristly hairs. The handsome flowers, which are freely produced in drooping clusters, are somewhat pear-shaped in outline, white, tinged with rose at first, but eventually changing to pink. During the month of June it is a most attractive plant, the white and pink flowers harmonising well with the hoary foliage. Seeds are produced freely and germinate readily if sown in a little heat in spring. O. album is a white-flowered form of it.

O. ARENARIUM.—This plant is a native of Eastern Europe and the Caucasus, usually growing in arid stony places. It is of somewhat bushy habit, with branching stems 1ft. high. The lower leaves are about 8ins. long and less than ½in broad, covered with stiff bristly hairs. The stem leaves are broader and sessile, while at the top are borne clusters of pendent pale yellow or nearly white flowers.

O. BOURGÆI.—A native of Armenia, this is a handsome species, with large, white, bell-shaped flowers in June. Like the above, this is a strong-growing plant and possesses hairy foliage. Being

Digitized by Google

a biennial, this species should be raised annually from seed, which is produced freely.

O. ECHIOIDES.—Some confusion exists as to the proper name of the common "Golden Drop" of our gardens. Both the names of O. echioides and O. tauricum have been applied to it, but the latter is evidently the correct name. The fine O. echioides is a native of Central Europe from the Pyrenees to the Balkans, and is a strong-growing, bristly plant of biennial habit. Its flowers, which on large plants are freely produced, are of a rather pale yellow.

O. SERICEUM.—This species is a native of Asia Minor. It has a rather woody stem, with many branches, bearing rosettes of silky grey leaves from 3ins. to 4ins. long. The leafy flowering-stems are from 6ins. to 9ins. long, while the flowers vary in colour from pale yellow to white tipped with pink. O. sericeum is a free-growing plant, doing well on sunny ledges or in rocky crevices.

O. STELLULATUM.—This is a most variable plant and has many synonyms, of which O. helveticum is one. The habit of this species is like that of the above, but taller. The pale yellow or citron-coloured flowers appear in May and June on stems up to 1ft. high. It is mostly biennial in habit in this country, the plants damping off in the winter after heavy flowering. As seeds are freely produced it is readily increased in this manner, and it succeeds well in poor soil in sunny situations. It is a native of the mountains of Central and Eastern Europe.

O. TAURICUM ("Golden Drop").—A name now proposed for this well known garden plant is O. viride, but it will probably always retain the older name. It is a good perennial, lasting and flowering freely for several seasons in a sunny, well drained situation. Sometimes, however, it will flower so freely that no barren rosettes are formed for the following year and the plant succumbs in the winter. Of sub-shrubby habit, the branched stems are furnished with tufts of narrow leaves about 4ins. long, covered with stiff hairs. The handsome bright yellow flowers are tubular, disposed in pendulous clusters with a few erect ones as they open. It usually blooms during the whole of the summer months, and even during mild winters is seldom without a few flowers. It is an ideal rock plant, providing an attractive display for a long period, with its drooping fragrant blossoms. This plant may be increased by means of cuttings stripped off with a heel any time during May and June, and inserted in sandy soil under a bell glass, or in a close frame. It is a native of Eastern Europe and Asia Minor.

Several other species of Onosma have been in cultivation from time to time, but they have been lost again—their want of persistency being probably due to their biennial character. W. I.

LOW-GROWING SHRUBS.—II

POLYGALA CHAMÆBUXUS is a dwarf Milkwort from 6ins. to 10ins. or 12ins. high with box-like foliage, and dainty yellow blossoms freely produced during April and May. The variety purpurea has purple flowers. They favour a moist soil and are readily increased by division.

The introduction of many dwarf species of Rhododendron offers great possibilities in the near future. The formal garden of dwarf Rhododendrons should be at least as interesting and beautiful as the heath garden of to-day. The belief that peat is essential for the culture of Rhododendrons no longer holds good. They will thrive on any lime-free soil. The European alpine Rhododendrons, R. ferrugineum and vars. album and major, R. hirsutum, which does not dislike lime, RR. intermedium, halense and myrtifolium, are old favourites, but they are such dainty dwarf shrubs they should be far more largely grown in our gardens. They rather favour a moist soil.

R. impeditum, or R. fastigiatum the name by which it was first distributed, is the most amenable of the dwarf Chinese species to culture in large quantities, being readily raised from seeds and increased by cuttings and layering. It is a dwarf tufted species with flowers in several shades of purple producing the first blooms when only eighteen months to two years old from seeds. Mr. George Forrest first introduced R. impeditum in 1911 and described it then and in subsequent sendings as a common shrub on open pasture-land. The flowering season is towards the end of April and during May. R. intricatum, introduced by Mr. E. H. Wilson in 1904, is lavender or lilac in colour and flowers two or three weeks earlier. This has not produced seeds with us, but is increased by cuttings and if the plants are given a good mulching of decayed leaf-mould they root freely all up the stems, soon giving plenty of young plants. R. flavidum (syn. primulinum) is a dainty evergreen shrub with small foliage, of rounded bushy habit, 1ft. or more in height, producing dainty pale yellow blossoms during April and usually a second display in autumn. R. Williamsianum is of quite a different type. It has the familiar dark glossy leathery green leaves and a low-growing spreading habit, rooting as it spreads into leafy compost, and delighting one in April with glistening pale rose bell-shaped flowers. It is an ideal rock-garden plant.

Rosa Wichuraiana is a prostrate shrub quickly clothing old tree butts, rocky boulders and sloping banks with trailing shoots, which sometimes reach 6ft. to 8ft. or more long in a season. Among the dark shining green leaves the panicles of pure white blossoms during July and August are very showy. Where it does well the prostrate form of the Common Rosemary, Rosmarinus officinalis prostrata is a charming plant. Coming from the Isle of Capri it is not so hardy as the type. I still retain vivid recollections of quantities of this plant flowering profusely in a Lymington (Hampshire) garden I visited in April, 1922.

Vaccinium Vitis-Idæa, the Cowberry, is a dwarf trailing evergreen with dark shining green leaves and pink-tinted white blossoms in May and June which are followed by dark red fruits. A British plant, it should find a place in the rock garden where the conditions are on the moist side, and in narrow borders devoted to the culture of interesting and uncommon plants.

Though they are on the borderline of hardiness, so that frost may sometimes take its toll of the plants, a list of low-growing evergreen shrubs should include a number of Veronicas. They are mostly natives of New Zealand, the following six being particularly desirable dwarf neat-foliaged shrubs. V. buxifolia, with white flowers in late summer, is a good plant for edging a shrubbery border; V. cupressoides has a distinct cypress-like habit and lilac blossoms; V. decumbens, white flowers; V. edinensis, tinted golden foliage; V. epacridea, a dwarf bushy habit and heath-like foliage and V. pinguifolia, small greyish-green foliage.

For a shady border among hardy Ferns and for the least favourable positions in the rock garden the Periwinkles are very useful dwarf evergreens. Vinca difformis, lilac blue, and V. major, large blue, are the strongest growing. Of V. minor there are some six or more varieties, making quite an interesting and showy group. V. minor, blue, and vars. flore pleno, flore albo, flore puniceo, foliis argenteis and foliis aureis are more or less descriptive names of the variation in the colour of the flowers and leaves.

For waterside planting and moist shady positions three dwarf Bamboos are worthy of attention, namely Arundinaria vagans (pygmæa), Bambusa disticha and Phyllostachys ruscifolia.

DWARF DECIDUOUS SHRUBS.

A favourite miniature shrub for the rock garden, Berberis Thunbergii var minor, usually attracts most attention in autumn when the leaves turn orange and scarlet. Sometimes a shoot or two may shew signs of reverting to the normal growth. These should be cut out to the base.

Two dwarf Birches are interesting, Betula humilis and B. pumila. They favour moist conditions, so should be planted in the lower parts of the rock garden or in the bog garden.

Cotoneaster adpressa is a distinct low-growing shrub introduced from China by one of the French missionaries about thirty years ago. It clings closely to the slopes of a rock garden and is distinct in habit and showy in fruit. The larger-growing C. horizontalis is one of the most distinct of all the Cotoneasters. In the open it spreads freely over the ground and is then seldom more than 2ft. high. Against a wall, however, we had a plant at Kew 10ft. high, suggesting that it is a good shrub for a low terrace wall. The formal flat branching of the stems has caused the shrub to be aptly described as the Fish-bone Cotoneaster.

Among the Cytisus section of the Broom family are several of our most valuable dwarf shrubs for the front of the shrubbery border and the rockery. C. Ardoini is a low decumbent shrub, a mass of rich yellow blossoms in April and May. C. Beani is a hybrid between the last named and C. purgans and produces its yellow blossoms in May. Cytisus decumbens is, as the name suggests, a spreading tufted Broom; it has small downy leaves and yellow flowers from May to July. One of the best rock-garden Brooms is C. kewensis, a chance hybrid found at Kew among a batch of seedlings of C. Ardoini, the other parent being, presumably, C. albus. The creamy-white flowers are abundantly produced during May. The Purple Broom, C. purpureus is a low, spreading bush bearing rosy-purple blossoms freely in May. If a few old growths are cut out each year after flowering, this induces vigorous young shoots. For shelving pockets in the rock garden or the front of the shrubbery border in full sun, there are few more beautiful dwarf flowering shrubs. The Hedgehog Broom, Erinacea pungens, which hails from Spain, is a dwarf, dense, tufted shrub of spiny habit, requiring a hot sunny nook to grow and produce the purplish blue flowers.

Among dwarf shrubs with yellow flowers the species of Genista are only rivalled by those of Cytisus from which they are not easily distinguished. For hot sunny slopes of well drained light soils (which should not be manured), the Brooms have few rivals when in flower, while their green stems are ornamental throughout the year. The best half dozen are G. anglica (Needle Furze), G. dalmatica, of dense tufted habit, G. hispanica (Spanish Gorse), G. pilosa, G. tinctoria var. flore pleno, valuable because it lasts so long in flower, and G. sagittalis, a showy dwarf Broom with winged stems which may be effectively planted as an edging to a shrubbery border.

Potentilla fruticosa, the Shrubby Cinquefoil, is one of the most cosmopolitan of all hardy shrubs. It inhabits both the Old and New Worlds, including Britain. It is not surprising that such a shrub is very variable in habit. The var. pyrenaica is an

Digitized by Google

alpine form of tufted habit. Among the newer Chinese introductions Farrer's 188 is a dwarf free-flowering form, and one of Purdom's introductions with rich yellow blossoms is named var. parviflora. An important feature is that these dwarf shrubs flower from early July until October.

The most interesting and distinct of all the dwarf deciduous Rhododendrons is R. kamtschaticum. Select a moist position with a western exposure. At Kew we give the plant a mulch of sphagnum moss. The plants average 3ins. or 4ins. high, above which push the rosy-crimson flowers usually solitary or in pairs.

Ribes alpinum var. pumilum, the dwarf Alpine Currant forms a neat compact bush. It is a slow-growing alpine shrub of which there is also a form with yellow foliage (var. pumilum aureum).

Spiræa bullata is a dwarf Japanese shrub for the narrow border of choice shrubs. The rosy-red flowers are borne in July or early August, the plants being usually under 1ft. high. Even smaller is S. decumbens with dainty white flowers; this is a gem among shrubs for the rock garden and comes from the Tyrol.

A number of dwarf Willows give variety and interest in the bog garden or planted along the sides of a stream in the rock garden. Chief of these are Salix Arbuscula and S. Bockii, male and female forms, which are showy in flower during late summer and autumn, S. Grahamii, S. herbacea, a small British shrub, and SS. lanata, myrtilloides, repens, reticulata and retusa. A. O.

THE CULTURE OF THE BEGONIA.—IV

THE following is, I think, a good selection of varieties in the different sections, but there are so many first-rate sorts in commerce, especially among the doubles, that several further selections of first-rate merit could be made.

Eighteen Double Varieties for Exhibition.

AMY, salmon rose in colour with large well formed flowers, the wavy petals being of good substance.

BLACK KNIGHT, the darkest-coloured crimson, flower of perfect camellia form. The habit is all that could be desired, combining great freedom with a dwarf, compact growth.

CANARYBIRD, a grand pale yellow that is very telling. Compact, yet free-flowering; the petals are cupped in form, giving the flower a splendid effect.

GENERAL JOFFRE, a brilliant shade of scarlet, very large and excellent habit.

GRAND MONARCH, in the forefront of the crimsons with flowers of immense size and great depth, the outer petals reflexing like a rose.

IRENE TAMBLING, in deep fiery orange, is an enormous flower and very free.

J. W. PYMAN, a giant glowing scarlet with shell-like petals of good substance; a vigorous grower and free bloomer.

LADY CROMER is world-famous for its enormous size, lovely pink colour and perfection of its form. The ground colour is pearl pink overlaid by a brighter hue, the edges of each petal paling off to a lighter shade and beautifully frilled. Another good point is its erect habit.

LADY TWEEDMOUTH, a gigantic rose pink of good habit and very vigorous, the edges of the petals being prettily frilled.

LORNA DOONE, light rose pink with reflexing outer petals and rosebud centre.

MRS. J. S. BRUNTON, lilac rose, very large and of perfect habit: a gem.

MRS. PETER BLAIR, famous in the show tents, white with a faint tinge of blush on the outer petals, of extra size and great substance.

MRS. A. J. KERRY should please lovers of "picotee" flowers, for it is one of the very best among the doubles with a broad band of rich rose to every petal. Compact yet free.

NURSE CAVELL, pure unblemished white, of compact habit and absolutely circular flowers.

PEACE is another famous exhibition variety, with blooms 5ins. to 6ins. across, thrown well above the foliage. The colour is cream, shading to yellow in the centre, deep and full.

PRINCESS MARY, another picotee-edged flower of a clear yellow with scarlet edge.

SNOWDRIFT, of good form and size and the purest and cleanest white.

WINSOME PARTNER, reddish salmon and quite distinct. Flowers of large size and very free-flowering.

Good Single Begonias.

ACQUISITION, pure white, large and of fine form.

AEROPLANE, orange suffused with copper, large and very erect.

ALEXANDER MCMILLAN, apricot, very large, with fringed petals.

CONQUERANT, a large cerise scarlet.

COUNTESS OF HARROWBY, lemon yellow, of excellent habit.

FAVOURITE, golden bronze, and a very telling exhibition flower.

GERMANIA, deep golden yellow, of erect habit.

LADY STUCKLEY, white, edged with pink and beautifully crested.

MISS LELLA, beautiful pink of superb form.

A TYPICAL WINTER-FLOWERING BEGONIA.

NORMA, velvety crimson, and one of the best.

SNOWDON, pure white and very fine.

Tuberous Begonias for Hanging Baskets.

ALICE MANNING, a lovely yellow variety with pendent flowers.

CORALLINA, a superb salmon pink with long pointed petals, giving a light and dainty appearance.

FLEUR DE CHRYSANTHEME, again salmon pink, very profuse in its flowering and most attractive.

GOLDEN SHOWER stands quite by itself, and is most beautiful, being prettiest of all in the half-opened stage, when it is the exact shade of Rose W. A. Richardson.

MARIE BOUCHET, a lovely variety with a great profusion of deep reddish flowers.

MRS. BILKEY, orange scarlet and will cross freely with other varieties.

ROSE CACTUS, rose pink with sharply pointed petals and smothered with flowers over a long period.

STARFISH, very free and striking, with flowers of a vivid rose crimson.

STELLA, a pleasing shade of red, the petals being long and prettily twisted.

Winter-Flowering Begonias.

SCARLET BEAUTY, vivid scarlet, double and semi-double blooms in handsome sprays, individual flowers 2ins. across. Dark green foliage.

ECLIPSE, salmon scarlet, semi-double, profuse and free, with glossy green leaves.

MR. T. H. COOK, rosy pink, one of the largest and a very perfect flower, 3ins. to 3½ins. across. Needs stopping or it will grow rather tall.

APRICOT, orange apricot in delightful sprays, very freely produced, foliage bronzy green.

DUCHESS OF WESTMINSTER, double pink, very free in growth and flower. Handsome deep green foliage.

CLIBRAN'S PINK, bright pink double, individual flowers 3ins. across, often as many as ten blooms to a spray, thus forming large trusses.

Crested Begonias.

Crested and frilled singles are not named, but sold either as seeds or tubers in mixture.

The blossoms are not so large as those of the best exhibition singles, but are very substantial and attractive.

Rex Begonias.

ARTHUR MALET, bright rose with a silvery gloss and green veins.

BRIAN BORU, bright green and purple with a silver band.

ERWIN, silver ground, margined with green and spotted with silver.

GLOIRE DES ARDENNES, silvery carmine margined with green.

HIS MAJESTY, rosy lilac with olive green.

M. HENRI MARTINET, bronze leaves, green zone sprinkled with red.

MRS. H. G. MOON, olive edged with a broad slate-coloured stripe blotched pink and red.

PRINCE CHARLES OF DENMARK, bronzy white with carmine pink.

Digitized by Google

Begonia semperflorens (for Bedding).

BONFIRE, carmine scarlet

LUMINOSA, fiery red with bronze foliage.

PINK PROFUSION, deep rose pink, profusely branched and very free.

TRIUMPH, snow white.

Narcissus-flowered Begonias.

A new race in a wide variety of colours in which the inner petals are joined into a large double "trumpet" with its edges waved and frilled.

Miscellaneous Kinds.

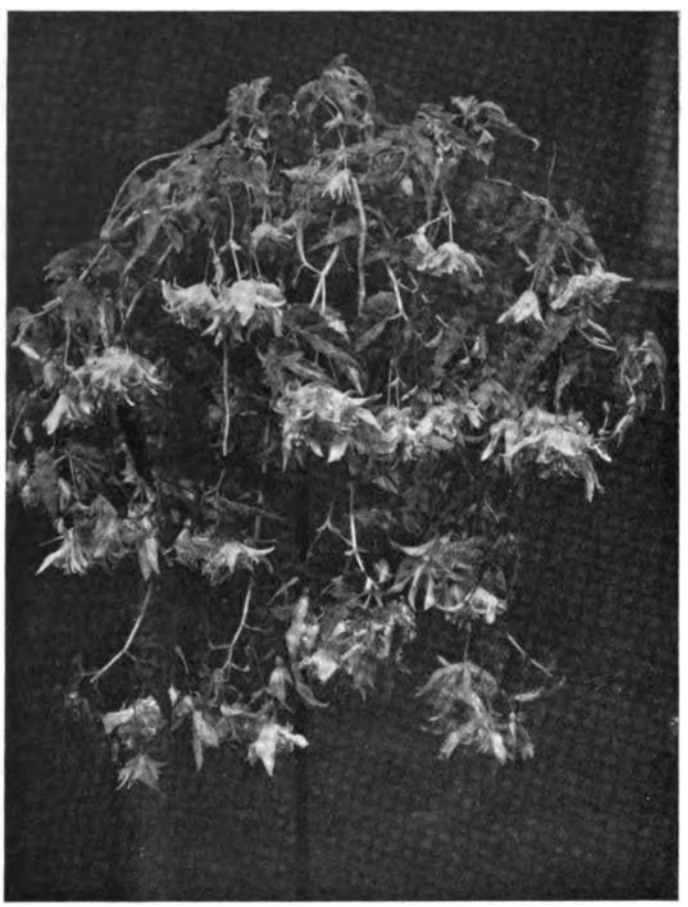
BEGONIA FULGENS, small typical leaves, green in colour overlaid with brown and a large number of red stems carrying medium-sized single five-petalled cherry crimson flowers.

COUNT ZEPPELIN, a variety largely used at Hampton Court for bedding, fully double starry flowers on erect stems, produced from early summer until late autumn. Very dwarf and bushy.

WORTHIANA, bright orange flowers, very freely produced on loosely habited plants. Showy and graceful.

HAAGEANA, tall grower, capable of attaining a great height, with reddish stems and bronzy green leaves thickly covered with hairs and bright crimson red on the reverse. In addition to this there are long pendent flower-stems bearing medium-sized flowers in trusses, these being pale rose pink with reddish hairs outside.

METALLICA, with handsome silvery green metallic-looking leaves and flowers, somewhat similar to the foregoing only rather deeper in colour and slightly smaller. A noble greenhouse plant when well grown.



THE REDDISH-COLOURED "BASKET" BEGONIA STELLA.

FUCHSIOIDES, a tall-growing plant with brown stems and masses of small deep green leaves, from between the axils of which appear pendulous trusses of vivid scarlet flowers, especially during winter and spring.

WELTONIENSIS, a tuberous-rooted form, of the easiest propagation by cuttings. The tubers push up annually a large number of thin dark red stems with light pea green leaves. Towards the end of summer the upper part of the plant becomes literally a mass of small pink flowers, somewhat like those of Gloire de Lorraine, but lighter in colour.

A Scented Begonia.

Among the novelties it should be remembered that there is now a variety which has added perfume to its other charms.

JOHN G. WHITE.—This is of good form, a pale rose pink deepening towards the centre, with the flowers emitting a delicious fragrance that is especially noticeable in hot weather.

Begonia fimbriata plena.

Another interesting range of flowers is B. fimbriata plena. The blooms are very double and exist in the usual range of colours, differing only in that the edges of every petal are beautifully cut, frilled and laciniated, giving to the flowers a most curious and striking effect.

Lorraine Type.

GLOIRE DE LORRAINE, noted for its masses of rich pink flower at midwinter. One of the most popular Christmas flowers and splendid in baskets.

AMABILIS, similar to above and very free, but flowering rather later.

ROCHFORDI closely resembles "Lorraine" in habit and freedom, but is nearer to red, especially in the bud state.

PATRIE, valued for its salmon red flowers, which have the great merit of not shedding.

GLORY OF CINCINNATTI, with strong branching spikes and individual flowers nearly 2ins. across.

GLOIRE DE SCEAUX, notable for its vigorous growth and the rich bronze colour of its foliage. The leaves are red on the underside, so that it forms a very striking winter basket-plant.

TURNFORD HALL, remarkable for its wonderful profusion of flowers, which are white, just tinged with apple pink.

Diseases of the Begonia.

Happily, the Begonia grower—in whatever direction his fancy may lead him—is not seriously troubled by plant pests; but although this is so, there are troubles that occur and "forewarned is forearmed."

Where eelworms are prevalent, all difficulty may be swept away by using only steam-sterilised soil. Green fly, again, occasionally proves troublesome, especially with winter-flowering forms. This can always be defeated by employing a nicotine fumigant, taking care not to use it too strong. Two or three repeated light fumigations are better than one heavy one. Thrip can be recognised by the dark streaks which it makes on the underside of the leaves. The great point with this pest is to deal promptly with it by free syringing, although it should never be forgotten that thrips do not appear where the atmosphere is kept sufficiently damp.

Mites are disastrous and, in spite of their minute size, capable of spoiling the plants. Their attack is directed to the growing tips of the shoots and the undersides of the young leaves, which become a rusty brown. Infected plants should immediately be isolated and dipped in a sulphur solution; 1½ gallons of water will dissolve 1oz. of flowers of sulphur mixed with 4oz. of soft soap. This should be repeated at least three times at intervals of five days, until it is seen that clean foliage is again developing. Keep everything about the plants as clean as possible and, whenever any trouble does occur, do not fail to fumigate the healthy plants as well as to deal with the diseased ones.

H. W. CANNING-WRIGHT.

NOTES ON SOME FRENCH ORCHIDS

ALL the hardy Orchids greatly appeal to plant-lovers, whether they are botanists or gardeners, not only on account of their infinite variety of form and colour, but because they possess an indefinable air of character which is lacking in many other even more showy plants. Only a very few of our native Orchids are generally common plants; most of them are so strictly limited in their distribution that in order to see all our indigenous species at home one must be prepared to travel from the South of England (and the Channel Isles) to the far North of Scotland, with the addition of a trip to the West of Ireland for two more species.

I suppose most keen gardeners have tried to grow a few of the native Orchids at one time or another, though they are plants which cannot be grown without a fair amount of attention. The publication of a new edition of M. Correvon's excellent work, "Album des Orchidées d'Europe," should do much to stimulate greater interest in hardy Orchids, and his cultural hints are very valuable. Although they object to being pulled up from their native soil in a rough and ready manner, if reasonable care is taken not to injure the tubers, Orchids may be quite safely transplanted while still in flower.

Many of the species which are extremely rare and local in our isles are quite common across the Channel. One of my happiest memories of a motor tour across France last summer is the recollection of a number of Orchids which were hitherto known to me only by name. Most remarkable of all is the Lizard Orchis (Orchis hircina) of which the popular name refers to the lizard-like appearance of the flowers; the specific name is derived from their very pronounced odour of billy-goat. In England the Lizard Orchis is regarded as one of the rarest of all native plants (though it is far more widely distributed than is generally known), so that it came as a surprise to find it growing by the dozen (sometimes by the hundred) along the roadsides in Tourraine and in parts of Central France. It is a tall, handsome plant, a well developed stem reaching a height of 3ft. or 4ft. and bearing a large number of its extraordinary green flowers. Before the flowers appear the plant bears some resemblance to a Mullein, and I allowed the car to run past several before I realised what they really were.

The Jersey Orchis (Orchis laxiflora) is a handsome, tall purple species, at one time established on ballast

Digitized by Google

heaps at Hartlepool, but nowhere indigenous in England. In parts of France (and in the Channel Isles) it occurs in abundance in marshy meadows, and is a much more attractive plant than any of our more common purple Orchids in which the flowers are borne in too compact a spike to display their full beauty. The graceful poise of the flowers of O. laxiflora is reminiscent of that of a Belladonna Delphinium. The little Burnt Orchis (Orchis ustulata) is very local in England, and I saw only one plant of it in France, on a steep limestone hillside above Abriès in the Queyras valley, at a height of about 5,oooft. The scattered red spots on the white lip of the flower have a very pleasing effect, and the result is a much prettier bloom than the text-books lead one to expect—a not infrequent occurrence with Orchids, by the way. Since dried Orchids almost always turn black, herbarium specimens give us little idea of the beauty of the living plants. The somewhat rare Fritillaria delphinensis was growing not far from the Burnt Orchis; it is apparently an alpine form of the Snakeshead of the Thames Valley meadows.

Orchis globosa is fairly plentiful in the alpine region, its very glaucous foliage rendering it distinct even before the flowers open. It sends up a stem about a foot high, bearing at its summit a crowded, compact head of pale pinkish mauve flowers rather suggestive of a pale variety of the Pyramid Orchis of our limestone copses. Orchis sambucina is a much more beautiful species, and its sturdy spike of yellow flowers makes a pleasant contrast to the many purple species. But O. sambucina is not always yellow by any means; it has a most beautiful deep rosy purple form as well, which is rather puzzling for the tyro to identify. In the neighbourhood of the Boréon cascade in the Maritime Alps (noted for the number of rare plants which grow there) both yellow and purple forms of this Orchid grow side by side. It would be interesting to know if intermediate forms occur and if each colour form breeds true. It should offer no great difficulties in cultivation, and a group of the two colour forms in the rock garden would be a charming sight. A few plants which I collected at the Boréon are coming up quite happily so far, on a level part of the rock garden, associated with small Gentians and other turf-forming plants.

Quite the most beautiful of all the Orchids which I had the pleasure of finding last year was Cephalanthera rubra, a rarity of one or two Gloucestershire woods. It was growing fairly plentifully in a thin limestone wood in the Department of Lot and again on the thickly wooded roadside bank near Molaretto, between Susa and the Col du Mont Cenis. I have never seen any illustration which did justice to the wonderful rosy blooms that look more like the product of a hothouse than of subalpine woodlands. Waving above the heads of the Orchids were noble plumes of Spiræa Aruncus, while Hepaticas (long since out of flower) nestled in the moss beside them. The Molaretto woods would well repay a visit from the plant-loving tourist; unfortunately, they are not very easy of access, as one cannot stay nearer than Mont Cenis.

From the Album des Orchidees d'Europe.

THE LIZARD ORCHID, ORCHIS (HIMANTOGLOSSUM) HIRCINA.

Epipactis latifolia is a familiar English plant and one of our least attractive Orchids. I was glad to make the acquaintance of E. atrorubens near Guillaumes in the Upper Var Valley, for it is a much more striking plant. The flowers and stem are suffused with rosy purple instead of being dingy mauve and green as in latifolia.

The Marsh Epipactis (E. palustris) was growing in boggy ground near Le Lautaret (the botanist's Mecca) in company with Gentiana asclepiadea, but the plants struck me as poorer than those which grow in such abundance on the wonderful Braunton Burrows in North Devon—a lovely white variety occurs there also. Limodorum abortivum is a curious rather than a handsome Orchid; it is a parasite on the roots of various trees. I saw it only once, in the neighbourhood of Rocamadour, and was considerably puzzled as to its identity. It is not a British plant, but, according to Bonnier and Layea, occurs "here and there" in France.

The Lady's Slipper (Cypripedium Calceolus) is, of course, one of the rarest of the rare among British natives, but in some of the more remote woods in the French subalpine region it must still be fairly common: I have never had the delight of seeing the Lady's Slipper at home; the nearest I saw last year was a large bowlful of freshly gathered flowers in a dairy window in a back street in Grenoble. Long may it continue to flourish undisturbed by collectors in its native haunts!

I did not see many Bee Orchids (Ophrys apifera) anywhere in France, except in the wood in Lot where Cephalanthera rubra grew. Here they were very fine and numerous, and among them I found two plants with white "wings" instead of the usual pink ones. The Bee Orchis is, of course, a typical limestone plant, yet it is curious to notice that an odd plant does occasionally turn up in a district where there is very little lime, and it is usually an exceptionally well developed and richly coloured specimen. When we see how erratic its appearance is in any one spot (even in a locality where it is common) it is not surprising that it proves itself troublesome to establish in our gardens.

To see the fragrant Nigritella at home one must leave the woodlands below and ascend to the haunts of the true alpine flora. Here, scattered in ones and twos, but in great numbers, it springs from a turf of Gentians, Milkwort, Campanulas and Alpine Clover—of which the incomparable fragrance seems to epitomise the spirit of the mountains. Sometimes the flowers of Nigritella are so dark as to be almost black, or they may vary from bright red to crimson. Whatever the colour, the delicious vanilla scent is the same, and one can seldom resist the temptation of gathering a bunch of the flowers for the sake of their fragrance.

Another truly alpine Orchis is the dainty little green-flowered Chamæorchis alpina, which can be recognised at once by its long narrow leaves. It is much rarer than Nigritella, and I only saw it in the neighbourhood of Mont Cenis. Another green-flowered species is the Frog Orchis, Habenaria (or Cœloglossum) viridis, which may be found at a considerable height in alpine meadows, though it also grows not uncommonly in English hayfields.

The Scented or Gnat Orchis (Gymnadenia conopsea) is the fragrant long-spurred purple species common in subalpine pastures and on turfy moors in Britain. I did not happen to see the white Butterfly Orchis, Habenaria (or Platanthera) bifolia plentifully anywhere in France, though no doubt it is as common in some districts as it is on the Welsh mountains.

The Tway-blade (Listera ovata) is as widespread in France as it is in England. It grows plentifully near St. Martin Vésubie at the side of the Venanson road, within a stone's throw of such local treasures as Campanula macrorrhiza, Hypericum Coris and Linum salsoloides.

N. G. HADDEN.

[The accompanying picture of the Lizard Orchid is reproduced from the excellent colour plate in M. Correvon's "Album des Orchidées d'Europe." M. Correvon's nomenclature follows, of course, Continental practice, but he gives a fairly complete synonymy for each species, so that it is easy to trace them.

The culture of most hardy Orchids presents no insuperable difficulty and those amateurs—and they are many—who want to grow "something different" might well take them up.—ED.]

FORTHCOMING EVENTS.

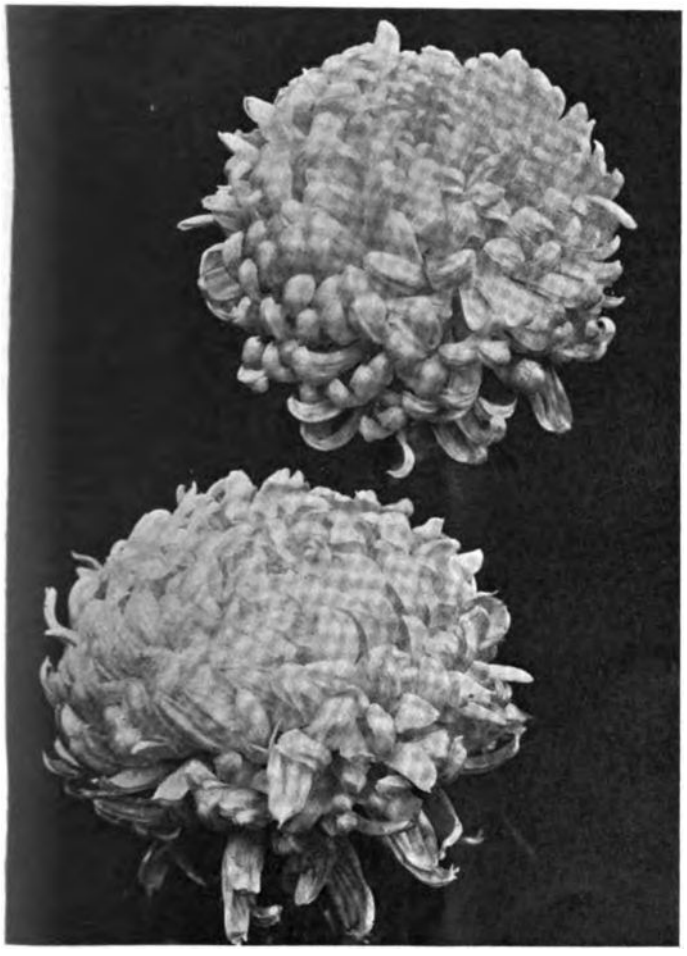
January 29.—Royal Horticultural Society's Fortnightly Meeting.

February 2.—Blackburn Horticultural Society's Meeting.

Digitized by Google

THE FIRST SHOW OF THE YEAR

THE exhibits and attendance at the initial Show of the year of the Royal Horticultural Society at Vincent Square, Westminster, on January 15, augur well for the future. As a rule the January displays are small and the attendance is meagre, but on the present occasion there was quite a large attendance and the hall was comfortably filled with an interesting variety of exhibits.



THE RICH YELLOW CHRYSANTHEMUM R. W. REIMAN.

Immediately inside the entrance there was a vivid group of greenhouse Cyclamens set up by Messrs. Blackmore and Langdon. For the most part the Cyclamens were grouped in shallow baskets containing a dozen or so of profusely flowered plants. These patches of glowing salmon, rose pink and crimson colours were very effective, especially when, as was the case with several varieties, the ample leaves were freely mottled. A basket of the frilled Mrs. Buckston attracted a deal of attention, but it was generally agreed that while the flowers were interesting, their form was poor and that the novelty did not compensate for the loss of the graceful shape and purity of colour. In marked contrast with these splendid greenhouse Cyclamens were the tiny blooms of the hardy varieties which Messrs. Carter, Page and Co. so well arranged in their charming little alpine exhibit. These tiny flowers always fascinate with their uncommon shape and rich colouring. The white variety is somewhat washy, but the substantial crimson of Cyclamen Atkinsii and the roseum form were very satisfying. This exhibit also contained pretty patches of Primula Juliæ of unusually dark colouring.

A pleasant little rock-garden was made by Messrs. Skelton and Kirby, and they planted it with various Ericas, Saxifrages and Iris unguicularis. The Misses Hopkins also had a seasonal rock-garden, and the more ambitious structure of Messrs. Wm. Cutbush and Sons was very successful. On the low levels they had some very floriferous groups of Christmas Roses, Iris alata and the old favourite Anemone Hepatica rosea. A step or so higher there were well berried little bushes of Pernettya mucronata and Hamamelis. A selection of alpine plants was displayed by Mr. G. Reuthe, who also had sturdy plants of Rhododendrons and various conifers. Daphne Mezereum and the double mauve Primrose were of interest in the exhibit of Mr. F. C. Wood.

Fresh and fragrant Violets were arranged by Mr. B. Pinney, and Messrs. Wm. Paul and Son brought a number of well grown Camellias. These were mostly bushes about 3ft. high, and they were well flowered. The single varieties included C. alba simplex, The Swan, Jupiter and Waltham Glory, while among the double-flowered varieties the red and white blooms of C. Gilesii and C. conspicua were very interesting.

In addition to the Cyclamens, greenhouse plants included vivid scarlet heads of Poinsettia pulcherrima with the rose and white forms shewn by the Hon. Vicary Gibbs; Hyacinths and Freesia refracta Excelsior, by Messrs. R. and G. Cuthbert; the quaint Tillandsia Lindeni, the blue Pycnostachys Dawei and Lapageria rosea, by Messrs. L. R. Russell, Limited; profusely flowered Acacia platyptera, Eranthemum pulchellum, Daphne indica rubra and Azaleas, by Messrs. Stuart Low and Co.; and the customary exhibits of carnations.

In addition to such excellent perpetual-flowering varieties as Edward Allwood, Wivelsfield Claret, George Allwood, Laddie and Topsy, Messrs. Allwood Brothers shewed blooms of their perpetual border varieties which had been wintered under glass. This newer type has considerable merits and a very long flowering season is claimed for the many varieties. The Fancy Carnations were prominent in an exhibit by Messrs. Stuart Low and Co., and these included Duchess of York, Ivanhoe, Mrs. Cheeney and Sheila Greer. Among the Carnations of Mr. C. Engelmann were Nigger, Topsy, Aviator, Laddie and Enchantress Supreme.

The Orchids were one of the features of the Show and Messrs. J. and A. McBean's gold medal group, in particular, attracted much attention. It was especially noteworthy for the many fine Cymbidiums and Odontoglossums it contained. Other firms with interesting groups were Messrs. H. T. Pitt, Cowan and Co., Saunders (who included the rare Saccolabium bellinum), J. Cypher and Sons, and Stuart Low and Co.

Sir Jeremiah Colman exhibited a very interesting group, largely consisting of variously coloured forms of Cymbidium Queen of Gatton. Some handsome forms of Lycaste Skinneri were also noted in this group.

A really magnificent collection of vegetables was set up in the best exhibition manner by Messrs. Sutton and Sons. Practically all seasonable vegetables were included and each displayed first-class cultivation as well as splendid type. Messrs. Geo. Bunyard and Co. had a small but brilliantly coloured collection of such Apples as Baumann's Red Reinette, Newton Wonder, Allington Pippin and Mére de Ménage.

A good many garden sundries were to be seen and the chief were Mr. Pinches' excellent labels, Messrs. Hawes' patent watering cans, the Wilmott plant stakes, Messrs. Allwood's Carnation supports, the Everyman's Seed Sower, garden gloves, Radium fertiliser, the Letchworth wall frames, garden statuary by Messrs. Sander and Co., and various jams and preserves.

Among the many exhibits of paintings of flowers and garden scenes the most interesting were those of Lilies, Rhododendrons, Eucryphia, Clianthus, Geraniums, etc., by Sir Herbert Maxwell. Mrs. Miller's studies of Indian flowers were also of considerable merit. Miss G. Dorrien-Smith again shewed pictures of subtropical plants, and others were contributed by Miss Alice Wilkinson and Miss E. Kirkpatrick. Mr. Percy Cane shewed excellent photographs of gardens made to his designs.

NEW AND RARE PLANTS.

Chrysanthemum R. W. Reiman.—This is an excellent late-flowering incurved Japanese variety, larger than is usual at this season and of rich yellow colouring. Award of merit. Shewn by Messrs. W. Wells and Co.

Primula obconica Bush Hill Blue.—The shade of colour is rather uncommon in the type of greenhouse Primula, but it is too variable and tends to become too washy to be generally popular. No doubt, after a few years' further selection, a good strain would be secured. Shewn by Messrs. Stuart Low and Co.

Cymbidium Queen of Gatton.—One of many splendid forms raised at Gatton, this has bold rosy-lilac blossoms with purplish lines and purple markings on the lip Award of merit. Shewn by Sir Jeremiah Colman.

Cypripedium Charlotte Dillon, Chardwar Var.—A fine variety with a bold white dorsal sepal with an emerald green base and heavily blotched dark claret; the lip and petals have a bronzy tint. Award of merit. Shewn by Mr. G. F. Moore.

Cypripedium Memoria F. M. Ogilvie, var. The King.—An especially fine form, large in size and excellent in shape, the large dorsal sepal practically half white, with a pale green base heavily blotched claret, the broad petals tinged brownish red. First-class certificate. Shewn by Mr. G. F. Moore.

Odontioda Columbia.—A splendid cinnabar red variety with large flowers of excellent form. First-class certificate. Shewn by Messrs. Charlesworth and Co.

WIREWORMS, LEATHER JACKETS AND CUTWORMS

WIREWORMS are simply the larvæ of the click beetle, and among the most destructive pests which attack vegetables. Though only about an inch in length, they are numerous and restless in their habits, and destroy far more than they actually need. They belong to the Elaters, and are thus related to the fireflies. They are of a wiry appearance, brown, with skin hard and polished, have six legs near the head and something like a foot under the tail segment. The eggs are laid in the earth, or on a food plant just above it, and hatch in about a month. They spend four years and sometimes five in the larval state, burying themselves more deeply in cold weather and eating any root they come across. When grown they build an oval cocoon like a lump of earth, pupate and, some in about three weeks, others in spring, emerge as click beetles about half an inch long and rather narrow in shape.

The remedies generally advised are dressings in the autumn, before spring-planting, of salt, lime, gas lime or a mixture of lime and salt. Alkali waste, kainit, Vaporite or napthaline may also be used. For traps, divided Carrots or Mangolds are useful, also small weed-heaps covered with boards or tiles. These traps should be carefully examined each morning. Of all remedies, however, birds are the most effectual.

Scarcely inferior to the wireworm in its destructive capacity are members of the cutworm tribe, which derives its expressive name not from any scientific relationship between its members but from their custom of biting (or cutting) through the stems of young plants near the earth. Most of these insects represent the larval stages of moths, but the "leather-jacket" is sometimes counted among them. This is the larva of the crane-fly (daddy-long-legs) and is very destructive to lawns and also to other plant growth of many kinds. It is well known in North America, and is sometimes called there the meadow maggot.

The perfect insect, a large gnat with long legs which break off easily, is well known, and in this form harmless. In both early and late summer, however, the females lay numerous long, black, shiny eggs, which hatch in two or three weeks into fleshy grubs with tough wrinkled skin of an unattractive brown. They have a small head and blunt tail. They remain in the larval condition but a few months, feeding near the surface of the soil in fine weather but burrowing deeper in frost. In the early summer the first brood pupates and, when ready to hatch, forces its way through the earth by means of bristles and two curved horns near the head until the pupa has the head and half its length in the air. The males hatch out with ease, and then, it is said, hunt about in order to find and help out some female, the latter often needing assistance in freeing herself fully.

It is at the time of emerging from the chrysalis, generally in the twilight, that the perfect insect is easiest to pick up and destroy, and the death of each female means the prevention of the deposit of at least a hundred eggs.

Remedies.—As damp is necessary to the health of the leather-jacket, it is important that ground should be well drained. Salt, lime, gas lime or alkali waste may be applied in the autumn previous to planting up ground or to the formation of a new lawn. If the ground is in suitable condition, neither too dry nor too wet, one of the napthaline preparations, such as Vaporite or Apterite, may be applied with excellent results. Burying the larvæ deeply will destroy some, also turning over the soil to expose them to light, heat and birds. Slates or boards may be laid on the ground and the grubs collected every morning and destroyed.

The more generally recognised English cutworms, three or four in number, are the larvæ of insects which sleep during the day and become active as the twilight deepens into night. The Americans call them owlet moths, and they are of the family Noctuidea.

Differing from each other in some details the general shape of the cutworm is that of a stoutly built caterpillar of medium size. Its habit in daylight is to remain curled just below the surface of the soil, waking at dusk to taste and destroy far more young vegetables than would suffice for their night's food.

In advanced summer or early autumn the later hatched insects lay their eggs, the larvæ from which feed and grow or hibernate, according to weather conditions, completing their growth in the spring, when many build earthen cocoons, pupate and after a few weeks emerge in their perfect form.

Prevention is most difficult. The ground should be carefully watched as digging progresses; while, after planting, soot or soot and lime, should be strewn freely between the plants, which may be dusted copiously with pyrethrum or other insect powder.

If their presence is made manifest, the ground should be examined at once and also after dark with a lantern, while slates and cut Mangolds, Carrots, etc., may be laid as traps to be looked over each morning. Against these, as for most other pests, the birds are exceeding useful allies. M. L. B

AN UNCOMMON BEDDING PLANT

SO far as my experience and observation go, Agathæa cœlestis is almost unknown, certainly not grown, in the vast majority of gardens, yet it is a charming and valuable plant for bedding out and for the cool greenhouse. It was a stranger here until I introduced it two or three years ago, since when it has given great pleasure. Of the two ways of using this Blue Daisy—under glass or in the open—it has always done best with me under the latter conditions, the plants growing bigger and flowering more freely. Its particular tone of colour may be described, I think, as a shade deeper than that of Plumbago cœrulea and the size of the flowers is about that of a shilling. Being of this quiet shade of colouring an odd plant put here and there does not do itself justice, but when the species is seen massed in a bed or in a large patch fronting the herbaceous border, it never fails to call forth the warmest praise.

Agathæa cœlestis is easily propagated from cuttings or seed, the former method being the easier and quicker way. Secure cuttings from early to mid-September and root them in pans or boxes in a cold frame. Here, if frost be entirely excluded, they may remain until potting time in spring. Where there is a doubt about the safety of the plants, remove them during cold spells to the shelf of a slightly heated greenhouse. The first touch of frost does not appear to hurt the old plants in the border, but the leaves gradually turn black after a few visitations, plainly shewing that risk should not be run. If desired the old plants may be taken up and boxed in the way usual with

Digitized by Google

many other bedding plants. They should first be cut back somewhat in order that they may take up less room and also to encourage fresh growth to break forth. A well drained soil conduces to an abundance of flowers.

Those in search of something fresh, at once easy to manage and sure to give a pleasurable return, might well try this Blue Daisy; its colour is quite out of the ordinary run of bedding-plant shades.

Ampthill. C. TURNER.

CORRESPONDENCE

OLD APPLES.

IN reading Mr. Lovelock's notes (January 5, page 14) I was struck by the fact that his description of New Bess Pool really applies to Old Bess Pool and not the newer variety. New Bess Pool (not Besspool, by the way, as it was named after Elizabeth Pool) was introduced by our firm two or three generations ago, and, curiously enough, after almost dropping out of cultivation, is being planted quite largely as a market Apple. It colours a deep crimson almost all over when fully exposed, is much softer in the flesh than Old B.P. and will not keep nearly so long, and is a fairly regular but not heavy cropper. The Old Bess Pool makes a wonderful tree on soil which suits it. We had some at Chilwell which were almost timber trees; one especially, I remember, must have covered some quarter acre of ground, and, when felled, 200 hedge stakes were cut out of its top. I remember my father saying he once sold the crop off seven trees for £70, but that was in the days when the British grower had no foreign competition to face. At the present time it is very doubtful if it would pay to plant, and no one should plant for his own use unless his dental arrangements are better than the average in these degenerate days, as, though sweet and of good flavour, it is desperately hard.—CHARLES E. PEARSON, *Lowdham.*

P.S.—Anyone with a good nose can tell New B.P. with eyes shut, as it has a scent absolutely different from any other Apple.—C. E. P.

THE SNAKESHEAD.

I SUPPOSE it is not surprising that Fritillaria Meleagris—a meadow plant—likes a little shade to its roots, but I must confess that I was surprised how much better some of mine did after they became overgrown during the war years. The "cover" in their case was weeds, but I find that dwarf Heaths, such as Erica darleyensis, answer equally well. My soil is light; on stiffer loams, root-shade seems less essential. I should like to have other readers' views on this point.—N. H. P.

SNAKESHEADS (FRITILLARIA MELEAGRIS) AMONG DWARF HEATHS.

THE ARRANGEMENT OF FLOWERS.

IT is the slack time now for flower shows and so it seems to me the moment to protest against the stereotyped arrangement of *cut flowers* that one sees in summer. The best thing palls by constant repetition, and I shun the very sight of the unvarying vases or bowls of Roses set up by professional florists. One would think that there were no other Roses in the world than Irish Elegance, Madame Butterfly or Fireflame! Were I a judge, I think I would bar them for a summer, just as I would those two good, but "over-shewn" old Roses, Frau Karl Druschki and Caroline Testout, so that new Roses and new hands should have a chance of shewing something fresh. How would it be to inaugurate a flower column where amateurs and professionals could air their fancies or their prejudices? It is high time that something should be suggested to judges and exhibitors.—E. H. W.

THE LABURNUMS.

AN error, no doubt in the printing, occurs in "A. O.'s" valuable paper on "Laburnums" (pages 15–17), to which I venture to draw attention because I frequently meet with amateurs who have not learnt to distinguish between L. alpinum and L. vulgare. The error consists in assigning the second half of May to L. alpinum as its flowering season, and June to L. vulgare, whereby the respective dates have been transposed. L. alpinum begins to flower just as L. vulgare begins to fade. I have good cause to endorse "A. O.'s" warning against planting Laburnums where cattle can get at them. Intending to beautify a piece of high road outside the park, I had both sides thereof planted with Laburnums. They grew well and arched over a field which was let for grazing, with the result that a valuable Clydesdale mare partook of the seeds and died. I do not know whether experiment has been made upon the foliage to ascertain whether it contains the toxic properties which undoubtedly exist in the pods and seeds. Certain it is that it is vain to plant Laburnum without protection against rabbits, which not only devour young plants, but gnaw the bark of mature trees, unhappily with impunity.—HERBERT MAXWELL, *Monreith.*

WINTER FLOWERS AT LA MORTOLA.

FOLLOWING seven months' drought we had one month of rain and, in December, several nights of frost; but in spite of these adverse conditions, on New Year's Day no fewer than 329 kinds of plants were in flower in this garden. Add to these the effect of trees and shrubs in fruit, plants with silver-grey foliage, specimen Palms and rare trees, and one can form some idea of what our many visitors call Paradise. I enclose you a list, feeling sure that you will agree with Mr. and Mrs. Cecil Hanbury, who think that it would interest many of your readers to know what can be grown here without artificial heat.—S. W. MCLEOD BRAGGINS, *La Mortola, Ventimiglia, Italy.*

List of plants in flower on January 1st, 1924: Abelia chinensis, Abutilon hybridum, A. striatum, Acacia acinacea and AA. Baileyana, cultriformis dealbata, decurrens, hakeoides, Hanburiana, lineata, longifolia, neriifolia, platyptera, podalyriæfolia, pubescens, Sieberiana; Asclepias curassavica, Agathæa cœlestis and A. hispida, Agave Sartorii, Ageratum mexicanum and A. m. nanum, Albizzia lophantha, Aloe abyssinica and AA. affinis, arborescens Milleri, a. natalensis, a. ucriæ, cæsia, ciliaris, Johnstonii, longiflora, percrassa, pluridens, rubro-violacea, Salm-Dyckiana, speciosa, s. hybrida, supralævis, Straussii, succotrina, Alyssum maritimum, Anagyris fœtida, Anemone coronaria, Antirrhinum majus, Aponogeton distachyum, Arbutus Unedo, Arctotis stœchadifolia, Arum Arisarum, Asparagus aphyllus, Azalea indica, Begonia Rex and BB. miniata and semperflorens, Bellis sylvestris, Berberis glauca, Bergenia crassifolia, Bignonia australis, B. venusta, Billbergia speciosa, Borago officinalis, Bougainvillæa glabra and var. Sanderiana, Bougainvillæa spectabilis and var. lateritia, Bouvardia coccinea and B. leinantha, Brachycome iberidifolia, Buddleia asiatica and BB. auriculata, madagascariensis and officinalis, Calendula stellata, Camellia japonica, Campanula Trachelium, Canarina campanulata, Cassia artemisioides, Caltha edulis, Ceanothus azureus, Centranthus ruber, Cestrum aurantiacum and CC. lanceolatum and roseum, Cheiranthus Cheiri, Chimonanthus fragrans, Chlorophytum elatum, Chrysanthemum anethifolium and CC. frutescens and hybridum, Cineraria stellata and C. hybrida, Cirsium gnaphalodes, Citrus Aurantium and C. medica, Clarkia pulchella, Clematis cirrhosa, Clivia miniata, Coleus thyrsoideus, Colletia cruciata and C. spinosa, Correa Lawrenceana, Colquhounia vestita, Coriaria sinica, Cotoneaster divaricata, Cotyledon macrantha, Crassula lactea and C. portulacea, Crotolaria capensis, Cyclamen persicum, Cydonia japonica, Cyperus alternifolius, Dasylirion glaucophyllum, Datura chlorantha and D. sanguinea, Dermatobotrys Saundersiæ, Dimorphotheca auriantiaca and D. hybrida, Diplopappus filifolius, Echeveria gibbosa and E. multicaulis, Echium plantagineum, Elæagnus pungens reflexa, Ephedra

altissima, Eriobotrya japonica, Erigeron Karvinskianus mucronatus, Eriocephalus africanus, Eucalyptus Globulus and EE. melliodora and sideroxylon, Eupatorium calaminthifolium and EE. grandiflorum and micranthum, Euphorbia triangularis, Euryops spathaceus, Felicia abyssinica, Fraxinus xanthoxyloides, Freylinia oppositifolia, Fuchsia triphylla and FF. hybrida, corymbiflora, splendens and arborescens, Fumaria officinalis, Gaillardia picta, Garuleum viscosum, Gasteria Lauchei, Gazania splendens, Genista monosperma and G. Moonlight, Gerbera hybrida and G. Jamesoni, Grevillea Priessei and G. Thelemanniana, Gynerium argenteum, Hakea cristata and HH. laurina and sauveolens, Hardenbergia Comptoniana and H. monophylla rosea, Heliotropium peruvianum, Helleborus hybridus, Hexacentris coccineus, Hebeclinium ianthinum, Hibiscus Rosa-sinensis, Hyacinthus romanus, Iberis semperflorens and I. sempervirens, Iochroma lanceolata, Iris germanica and I. unguicularis and var. alba, Jacobinia magnifica and JJ. pauciflora and penrhosiensis, Jasminum nudiflorum and JJ. primulinum and odoratissimum, Kleinia ficoides and KK. neriifolia, articulata, odora and repens, Lantana Camara, Lathyrus odoratus and L. sativus, Laurus nobilis, Lavandula abrotanoides and L. dentata, Leonotis Leonorus, Leptodermis lanceolata, Leptosyne gigantea, Linaria hybrida, Lobelia speciosa, Lœselia coccinea, Lopezia miniata, Lytanthus salicinus, Matthiola hybrida, Mahonia Bealei, Malvaviscus mollis, Megasea cordifolia, Mesembryanthemum atropurpureum and MM. æquilaterale, confertum, curviflorum, diversifolium, linguiforme, productum, reptans, roseum, rubricaule, Salmii, subincanum, uncinatum, sp. 10 Pretoria, sp. 21 Pretoria and sp. 6929 Pretoria, Mammillaria rhodantha, Monstera deliciosa, Montanoa bipinnatifida and M. tomentosa, Moricandia arvensis, Muehlenbeckia complexa and M. platyclada, Narcissus canariensis and N. Tazetta vars. aureus, pachybolbos and polyanthos, Nemesia strumosa hybrida, Nemophila insignis, Nerine Bowdeni, Nicotiana glauca and N. sylvestris, Odontospermum sericeum, Olearia Forsteri, Oreopanax capitatum and OO. dactylifolium and palmatum, Orobanche ramosa, Osmanthus Aquifolium and O. fragrans, Othonna crassifolia, and O. triplinervis, Oxalis cernua, Passiflora capsularis, Pelargonium lateripes and PP. peltatum and zonale, Photinia serrulata, Phylica rosmarinifolia, Pilocarpus pennatifolius, Piper excelsum, Pithecoctenium buccinatorium, Plumbago capensis, Poinsettia pulcherrima, Polygala myrtifolia, Polymnia silphioides, Primula kewensis and PP. malacoides, obconica and sinensis, Raphiolepis indica, Reinwardtia trigyna, Reseda Phyteuma and R. odorata, Rhamnus Alaternus, Rhipsalis Cassytha and R. paradoxa, Richardia africana, Rosa Banksiæ and RR. Bourbonia, Fortuneana, indica (and var. major), sinica Anemone, viridiflora and Thea, Rosmarinus officinalis and var. humilis, Ruscus Hypoglossum, Russelia juncea, Ruta graveolens, Salvia attenuata and SS. cacaliæfolia, chamædryoides, discolor, Grahami, Heerii, involucrata, leucantha, leonuroides, mexicana, pulchella, semiatrata and Sessei, Sarcococca pruniformis, Satureia viminea, Schinus Molle, Sempervivum arboreum and S. holochrysum, Senecio angulatus and SS. grandifolius, hadiensis, longifolius, mikanioides and Petasitis, Sida mollis, Solanum Hartwegi and SS. jasminoides, lycioides and nigrum, Sphæralcea umbellata, Statice brassicæfolia, Streptosolen Jamesoni, Tacsonia manicata, Tecoma capensis, Templetonia retusa, Tetrapanax papyriferum, Thunbergia coccinea, Tournefortia Messerschmidia, Tropæolum majus flore pleno, Ulex europæus, Verbena officinalis, Veronica salicifolia, Vinca major, Viola odorata, Visnea Mocanera, Westringia rosmariniformis, and Yucca elephantipes.

WHAT ARE ALPINE PLANTS?

I AM not surprised that Mr. James Parkinson (page 9), has given up trying to define alpine plants in a word or two that would be correct generally. The plants we grow on a rockery because they are dwarf and otherwise suitable cannot be put into one category and named accordingly. There are high alpines, such as Ranunculus glacialis, Saxifraga cernua and S. sedoides, that can be grown only with the greatest difficulty in lowland gardens. S. cernua grows on the top of Ben Lawers (3,984ft.), and nowhere else in Britain. The slightest coddling in a cold frame very soon kills it even in winter. Suppose we take S. oppositifolia as another type of alpine. On the southern shores of the Moray Firth this grows on dripping rocks within fifty feet or less of the salt water, and is easily killed in a cold frame. Sedum roseum, Silene maritima, Armeria maritima (Thrift), and Plantago maritima are plants which grow on the seashores or on the mountain tops. The Armeria has been found at an elevation of 3,800ft. No one would call these alpine plants; nor any others which grow at sea level and ascend mountains. In a general way there are high alpines which do not descend below a certain high altitude; and low alpines which do not descend below a certain lower altitude. Certain lowland plants ascend the mountains; and if we go far enough north we find alpine plants at sea level. In the eighties and nineties of last century when hardy plants were becoming popular, and prizes were offered at shows for alpine plants, the horticultural journalists criticised the plants that were exhibited as alpines. If we call them rock plants, however, even Saxifraga oppositifolia often grows among the turf in the Highlands and not on rocks at all!—J. F.

HELIOTROPES: THEIR VALUE FOR WINTER FLOWERING.

COMPARATIVELY few regard Heliotropes from a winter-flowering aspect. They associate them with summer and genial sunny conditions, propagating and growing them on and welcoming their fragrant blossoms as they appear from May onwards. It is not because of any particular difficulty experienced that our greenhouses are devoid of their perfume in winter, but rather through lack of forethought and arrangement. The cuttings which we are accustomed to propagate in spring and then pot on, will, if we so desire, bloom as well from September as in the summer months, provided they are prevented from spending themselves in flowering before the autumn, and are encouraged instead to make growth and ripen the wood preparatory to the plants being brought into the house, and maintained in a genial heat throughout the winter. It is largely a question of time-table: whether we shall permit them to have their own way from the start and flower, or whether we shall pinch out the buds until later in the year, when their delightful fragrance is doubly welcome. Fortunate are those gardeners who are able to plant Heliotropes out in a border inside a lean-to house and give them the run of the back wall. I have a distinct recollection of such a house where the strength of the three old plants was conserved for providing flowers in winter, and how early those trusses came on the branches which clambered over wires nailed to the chimney breast! White Lady and President Garfield were the varieties selected, and their output was great.—CLAREMONT.

ANDROSACE PRIMULOIDES.

I HAVE for several years now cherished a very beautiful plant as Androsace primuloides, only to be told by a friend who is something of a botanist—which I am not—that it is wrongly named. Can some reader, I wonder, enlighten me on the matter. The plant I have is like a smaller and more beautiful A. sarmentosa, about the size of the hybrid A. Chumbyi, in fact, but much silkier and more beautiful; the flowers, also, are more shapely.—R. W.

ANDROSACE "PRIMULOIDES" IN THE MORAINE.

[Botanically speaking, our correspondent's plant is not primuloides—the true plant being probably not in cultivation—but this form of sarmentosa which comes near Chumbyi is always given the name in gardens, and no one, so far, seems to have found it another! A. Chumbyi is *reputed* to be a hybrid between AA. sarmentosa and villosa, but this seems very doubtful. Until such parentage can be proved it is best considered as a form of A. sarmentosa.—ED.]

VARIATIONS OF VIOLA LUTEA.

IN Vol. LXXXVII, page 641, when Mr. T. Ashton Lofthouse was discussing "Alpines from the Pass of Mont Cenis," he introduced Viola lutea and some of its variations, and afterwards made an apology for doing so. There was no need for an apology concerning the most beautiful of the British Violas, which occurs not merely in the North of England, but on the Welsh and Scotch mountains and in the valleys of the latter. I have found it on the banks of the upper reaches of the

Digitized by Google

River Tay, but more plentifully in the adjoining meadows, where the typical yellow and paler forms were in the minority and V. lutea amœna in a variety of shades was abundant. Higher up the valley, in Breadalbane, a small meadow or paddock was purple with a variety of V. l. amœna in which the upper petals were intense purple and the lower three paler purple. I also found a wholly blue form at an altitude of 2,000ft. The plants were not so gregarious at this elevation as in the valley, doubtless owing to the steepness of the declivity upon which they grew. Concerning this species of Viola, we may remember that James Grieve of Edinburgh commenced hybridising the common show Pansy with the yellow V. lutea gathered on the Pentland Hills in 1862. In the following year he used also V. l. amœna and V. cornuta. With the influence of these two species he imparted a more perennial character to the Pansy, and gave to the new race that tufted habit and power to produce suckers which enabled the plants to bloom all the summer. The new race was termed Viola and Tufted Pansy by different people. Both terms are correct, though there was a struggle for some years as to which name should be used.—HORTULANUS.

HYACINTHUS AMETHYSTINUS AND ITS WHITE VARIETY.

"THE charming little Spanish Hyacinth (not the more robust Scilla hispanica, but the slender thing whereon Linnæus bestowed the name of Hyacinthus amethystinus)," so writes Sir Herbert Maxwell in his new book, "Flowers: A Garden Note Book." He goes on to suggest that the great botanist must have named the plant from a discoloured herbarium specimen. It is anything but the colour of an amethyst, even of those pretty pale coloured crystals which I collected when I was in the *Ultima Thule* of Irish civilisation, Achill Island. The small pendulous flowers are a real pale blue, and their length and narrowness, together with the slenderness of the main stem from which they hang, give the whole plant a great air of refinement. This beautiful Hyacinth grows from 9ins. to 1ft. in height and is quite hardy. There is a white variety which is more expensive, but which I do not think can hold a candle to the better-known blue. Readers will gather I am reading Sir Herbert's book. In that book I came across a touching reference to the late Miss Frances Hope of Warden Lodge, Edinburgh. I had not looked at her book for an age, so down came "Flowers and Gardens." I mention this because on page 201, in writing about our wild Geraniums and Erodiums, she asks this question: "Is the white variety of a plant usually earlier than that which is of the normal colour?" She instances "Sisyrinchium grandiflorum and Ribes, Hawthorn and Horse-Chestnut," also Ajuga reptans. Is there anything in it? I have no records of the opening of the little blue and white Spanish Hyacinths; but does the white flower first?—J. J.

FREESIAS AND "DUDS."

MR. DALRYMPLE seems to be, in the first part of his note in THE GARDEN for January 12, under the impression that I am carrying out *his* cure, but in the second part he clearly points out that what I do is different from what he does? Which does he mean?—JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Spinach.—In many gardens this vegetable is highly prized about this time, so make a small sowing in the open ground, provided the weather is suitable. Occasionally, the crop is destroyed, but there are times when it is a success. In any case the seed is cheap, and it is not much trouble to make another sowing later. Select a sheltered border and sow the seeds in lines 1ft. apart.

Seakale.—As the plants are lifted for forcing it will be necessary to secure some of the roots for providing plants for next year. The "thongs," as they are termed, are cut into pieces 5ins. or 6ins. in length, the top being cut square, and the lower end obliquely. This will enable the planting to be carried out expeditiously later on. Tie the roots in bundles, then place them in an upright position in the open and cover to the depth of a few inches with ashes or soil.

Horseradish.—This crop is well worth more attention than it generally receives, and now is a good time to lift the crop and select the best roots for future use. Store them in ashes in a cool place. The small roots may be planted in lines 1ft. apart, with a space of 9ins. allowed between the plants. Deeply trenched soil is advised, but all manure should be placed at the bottom of the trench. The old bed should be cleared of all small pieces of roots or they will prove detrimental to future crops.

Digging and Trenching.—This work should be proceeded with, and manure wheeled on the vacant plots. If not already done, a dressing of manure may be afforded the Asparagus beds, or, where it is available, seaweed is an excellent substitute.

Endive.—The best way to blanch Endive is to tie the top of the plants with a piece of raffia, and then to cover each one with an empty flower-pot, taking care to exclude all light. A few plants should be dealt with at a time; a supply can then be kept up for several weeks. Look out for slugs or they will devour the whole plant.

The Flower Garden.

Bedding Plants.—Cuttings of Zonal and Ivy-leaved Pelargoniums will now require attention and should be potted off singly in 3in. and 3½in. pots. A few leaves placed in the bottom of each pot will suffice for drainage. Grow the plants in a warm greenhouse or pits and when re-established keep the roots well supplied with water. At this season it is advisable to ascertain the approximate number of plants that will be required for the beds, what kinds they will be filled with, and any alterations in the schemes that are likely to take place. With this information, the grower can get to work, and next May he will have no difficulty in filling the beds.

Cannas.—These are still used for bedding purposes and may be raised from seed, but a high temperature is necessary to secure germination. When this has taken place the seedlings should be potted singly, and grown on in a warm house, being removed to the beds or borders in June. They will need repotting as they fill their receptacles with roots, and should be provided with a rich rooting medium.

The Rock Garden.

General Work.—Any alterations decided upon should be finished at an early date, and the whole made clean and tidy. The immediate surroundings may need attention, shrubs and trees that were planted when the rock garden was made will probably require curtailment, and in some cases their removal will be necessary. The bogs will perhaps need overhauling and fresh soil and the strong-growing plants to be lifted, divided and re-planted. The whole of the garden should be carefully looked over. Plants not thriving may be given another station with a different aspect, others more robust may be reduced to prevent them from encroaching on their less active neighbours. As the work proceeds a top-dressing of soil should be afforded.

Fruit Under Glass.

The Orchard House.—This is usually an interesting structure, and as a rule very little fire heat is needed, excepting perhaps when the trees are in bloom and the fruit is setting. About this date the pot trees should be placed in position, and plunged to the rims of the pots to prevent rapid evaporation. In addition to Peaches and Nectarines, Figs and the best varieties of Cherries and Plums may be grown in the orchard house, also Apples and Pears, providing the temperature is not kept too high at the start. At present the house should be closed early in the day, and a little fire heat will only be required when there is any likelihood of frosts. Damp the floors to create a slightly moist atmosphere, and when the weather is bright, a daily syringing of the trees will be beneficial, but such work should be done sufficiently early to allow the trees to dry before sunset. Keep the roots moist and when the trees are in bloom a circulation of air is essential, but direct cold draughts should be avoided. Stop spraying the trees until the fruits have set and just prior to the blooms opening the house should be lightly vaporised to destroy any aphis that may be present. This is important, because many shoots and crops are ruined by black and green fly if these pests are allowed to make headway.

Melons.—Where accommodation is available, such as heated pits or low houses, a few seeds may be sown singly in small pots. A little bottom heat is needed to raise the seedlings. When they appear, place them near the glass. A temperature of 65° is required, with a rise of a few degrees during the day. Do not over-water the soil or the young plants may decay. T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Herbs.—Mint, when left long in one position, deteriorates in quality, and is often attacked by a species of rust. Fresh plantations may be made now in fairly rich soil. Take out shallow trenches about a foot apart and lay the roots along the trenches or drills as they might be called. Clumps of Pot Marjoram should also be broken up every few years and fresh plantations made. If Sage and Thyme were sown last season they should now be planted out.

Hoeing.—Whenever the soil is in working condition the Dutch hoe should be plied between the rows of Lettuces, Spinach, Spinach Beet or Seakale Beet, and autumn-sown Onions. This will aerate the soil and destroy to some extent the eggs or larvæ of various pests.

Potatoes.—An eye should be kept on seed Potatoes, and if early varieties are backward in sprouting they should have the benefit of a rather higher temperature. On the other hand, if later varieties are making too much growth they should have more light and cooler quarters.

The Hardy Fruit Garden.

Winter Spraying is a wise precaution and should not be omitted. Though past the usual time for carrying through the operation, it may still be done with safety. Those who cannot prepare their own mixtures should use a proprietary spray, such as Cooper's Winter Fluid, which is sold with full directions for use.

Bush Fruits.—The soil should be lightly forked over and, if necessary, manure in some form should first be applied. On heavy soils a light dressing of lime will prove beneficial. Planting may now be taken in hand, as the bushes will have time to make some fresh roots before the drying March winds set in.

The Flower Garden.

Bedding Plants.—Various bedding plants may now be propagated by cuttings. These include Lobelia, Salvia patens, Heliotrope, Ageratum, Cupheas platycentra and strigillosa. Seeds of Lobelia, Ricinus communis (Castor Oil Plant) and the Blue Gum (Eucalyptus Globulus) should now be sown in the forcing house or the early vinery. Autumn-struck cuttings of Geraniums should be potted up into 3in. or 3½in. pots and accommodated on a temporary staging in the early vinery. Specimen Fuchsias (for dot plants) which have been resting should now be placed in gentle heat to start them into growth.

Dahlias.—The tubers should now be taken from their winter quarters and placed in gentle heat so that they may furnish cuttings a few weeks hence. If forced into growth too rapidly the cuttings will lack stamina and cannot produce plants of the best quality.

Jasminum nudiflorum.—As soon as this winter Jasmine has finished flowering it should be pruned. It flowers on the young wood, so the shoots which have just borne the flowers should be severely thinned out to make way for young wood to bear next season's crop of bloom.

Wall Plants.—There is a wealth of plants suitable for covering walls. During the next few weeks planting may be carried out. The following plants are well tried favourites: Buddleia globosa

Digitized by Google

(orange), B. variabilis magnifica (violet), Ceanothus dentata, C. Gloire de Versailles, Clematises in variety, Cotoneaster frigida, C. microphylla, C. Simonsii, Cydonia japonica, Escallonia macrantha, Forsythia suspensa, Kerria japonica, Polygonum baldschuanicum, Wistaria chinensis, Vitis Coignetiæ and Ampelopsis Veitchii. This selection covers the four seasons and includes flower, foliage and fruit, and all will succeed in a medium loam.

The Pleasure Grounds.

Restoration.—On wet or stormy days, tennis nets should be overhauled and repaired if necessary, garden seats may be painted, finishing with a coat of varnish which gives the paint a richer appearance and also acts as a preservative. Lawn mowers, too, may in such weather be taken to pieces and the bearings and pinions thoroughly cleaned. CHAS. COMFORT.

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Chrysanthemums.—Cuttings of the decorative varieties should be secured this month, selecting stout, sturdy shoots from the base of the plant, as cuttings taken from the hard stems seldom make good plants. The cuttings should be about 3ins. to 4ins. in length, and they may either be inserted closely together in 48-sized pots or put in shallow seed boxes. Although it is usual to insert the cuttings singly in small pots when growing plants for exhibition blooms, this is not necessary in the case of the ordinary decorative varieties. If a slightly heated case is available, the cuttings will root more quickly, but this is not really necessary as they will root in unheated cases or cold frames. Where no other accommodation is available, the pots may be stood in shallow boxes and covered with sheets of glass. Whatever means of propagation is employed, damping should be guarded against; thus a little air should be left on the cases during the night, while the lights or covering glass should be wiped dry every morning.

Cannas are very useful for conservatory decoration during the summer and autumn months, and, where it is desired to grow them in small pots for furnishing the stages, a quantity of strong rhizomes should now be started in a temperature of about 60°. They may either be laid out in a bed until they start into growth, or strong rhizomes may be placed directly into 48-sized pots, using a rich compost, as these plants are gross feeders. As the rhizomes are very apt to damp off at this stage, water should be very carefully applied until they have started into growth and made a quantity of roots. Their next shift should be into 6in. pots, in which they will flower. Under this method of cultivation the growth should be restricted to one strong shoot. When in full growth they enjoy ample feeding, using diluted liquid manure or soot water alternated with guano or some approved fertiliser.

Hippeastrums.—A batch of bulbs should now be introduced to a warm forcing-house, where a temperature of 60° can be maintained. It is an advantage if plants can be selected that do not require repotting. Those that were started early last year are the best because they have finished their growth correspondingly early. Such bulbs will start more readily than those that have more recently matured. The plants should be thoroughly soaked at the roots, afterwards removing some of the old top soil, which should be replaced with a rich compost to which some fine bone-meal has been added. At the same time examine the bulbs for mealy bug, which, if neglected, will soon ruin a collection. The pots should then be plunged in a bed with bottom heat at command. This is not really essential, but without bottom heat they will not grow so quickly. If the plants are in bad condition at the root, they should be shaken out and repotted in fresh compost, which should consist of a good mellow loam with a little flaky leaf-soil and enough sand to keep the whole open and porous; a 6in. potful of fine bone-meal may be added to every bushel of compost. Before repotting, all dead roots and decaying matter should be carefully cleaned off. Large pots are not necessary, 6in. or at most 7in. being suitable for the largest-sized bulbs. At this time newly potted plants should be plunged in a bed with bottom heat at command. Water should be very sparingly given at the root until a quantity of new roots are produced and top growth commences. When in full growth they, of course, take ample supplies of water at the root. Hippeastrum seed is best sown as soon as it is ripe, but anyone who wishes to raise the plant from seed can do so at this time. Sow the seed in a light compost, cover lightly, and plunge the seed-pans in a warm bed, where the seeds soon germinate. The seedlings should be pricked off into pans or boxes, and, when large enough, may be potted off singly into small pots, or they may be planted out in a raised bed in a warm house, where they require less attention than when grown in pots. Whatever method is adopted, the young plants should be grown straight on without drying off until they attain flowering size.

Rhodochiton volubile.—This charming climber is a beautiful plant for the greenhouse. Although it is really at its best in its second year when planted out, yet it may be treated as an annual, growing it in pots to train to wires or pillars in the conservatory. For this purpose seed should be sown some time this month. The thin seeds should be covered very lightly or else they are apt to decay.

Grevillea robusta.—Seeds of this elegant plant should be sown now. The seeds are very apt to decay if covered too deeply, so should therefore be set on edge or very lightly covered.

Royal Botanic Gardens, Kew. J. COUTTS.

ANTIRRHINUMS

THE splendour of July's display depends greatly upon the care bestowed upon the raising of seedlings now. Close observation over a period of several years has convinced me that a week's difference in the dates of sowing seed does not make an appreciable difference to the date on which the first flowers will open, but it does make a very considerable difference to the vigour and profusion of secondary growths as well as to the length and development of the first spike, supposing the plant is grown on without pinching the leading growth. It is therefore a great advantage to sow seeds before the end of January, if possible, and certainly not later than the first week or ten days in February. Seeds sown later than that will produce plants that flower, but the substance and quantity of bloom will fall far short of the earlier plants.

At the same time it may be acknowledged that where Antirrhinums pass safely through the winter, the later plants which produce less flowers during their first season generally do much better the second season than those sown early. Indeed, open air sowing in March is my preference for plants that are to be depended upon for a second season. These latter make sturdy growth, produce a fair amount of bloom in August and September, and often right through October. They will commence blooming again with much profusion the following spring, maintaining a wonderful show of colour from May to the end of July. Of course, the individual spikes and pips on a second year plant compare unfavourably with a well grown first year seedling.

The cooler the atmosphere, above freezing point, the better for early Antirrhinums. The aim should not be to encourage a large amount of soft top-growth. It is the early development of a good root system and the production of a stiff, stout, short-jointed trunk or main-stem that makes for success in summer.

The recommendation is so commonly made that seedlings should be grown on shelves near the glass that it is generally accepted as the only proper way. I have practised it myself, and have no wish to condemn it, but, having about a quarter million plants to raise, and fearing some of that large quantity might suffer through unavoidably delayed attention, I had a bed of soil 6ins. deep made up on a greenhouse stage with corrugated iron bottom, and the seeds were sown on this bed, with bamboo canes laid across to mark divisions between the varieties. The health and uniformity of that batch was the greatest I had ever had, and that is now my method of raising. The greater body of soil made watering far less necessary, and the changes of temperature were less violent. Continuous use of the watering can is not beneficial to seedlings although it is very essential where shallow trays are hoisted on shelves near the glass, surrounded by the hottest air in the house and exposed to the full power of the sun, which even in winter can have considerable effect through glass.

An extensive bed of soil even on a greenhouse stage is very different from boxes filled with soil, but where the quantity of seed to be sown is small, or where a bed cannot conveniently be made I would certainly declare preference for a box 6ins. deep, half filled with drainage and rough soil siftings, and a couple of inches of prepared soil on top rather than a 2in. tray filled with the prepared soil. This is for the seed sowing, not for the seedlings when pricking out time comes.

As to pricking out, if this can be done as soon as four leaves are well formed, care being taken not to kink the tender stems while handling losses will be reduced to a minimum. It is when seedlings are left to become crowded above, with roots tangled and matted below, that failures in transplanting assume large proportions.

If the plants are to be grown in boxes until bedded out the depth of the boxes should not be less than 3ins. with about an inch of soil siftings in the bottom. If it is intended to pot the plants as soon as large enough boxes 2ins. deep are quite deep enough. It does, undoubtedly, pay to pot young Antirrhinums if the best possible results are desired.

After either pricking out or potting, it is wise to keep the soil rather on the dry side for a week or ten days. Obviously the plants must be watered in, for flagging cannot be tolerated, but after the one watering the roots will make better progress in tolerably dry soil until growth becomes active again, when the ordinary system of watering must, of course, be resumed.

The ultimate object in view must decide the question of "stopping" the seedlings. If the aim is to produce specimen spikes of bloom for exhibition the plants should not be stopped at all, but must be grown on as single stem plants, pinching out side growths as they appear. It is quite essential that such plants should be potted, and small sticks should be provided to support them. For bedding purposes it is necessary to pinch out the point of the main stem, and this should be done early, say when the tall growers are 2ins. high and the intermediates 1½ins.

Never coddle Antirrhinums; let them have plenty of ventilation even in the small stage. Always bear in mind that the real object of early sowing is not to procure big plants at bedding time. Plenty of roots and small tops should be the aim.

I have come across amateurs, anxious to grow specially fine Antirrhinums, who have actually commenced feeding the plants while in the boxes. That is as futile as it is dangerous. If the young roots are not damaged by an overdose of fertiliser, the stems and foliage will be urged into soft, rank growth that will be the reverse of helpful to the production of good flowers. Even in the preparation of the beds for Antirrhinums it is unwise to be liberal with rank manure. Nothing that tends to make the soil loose and spongy will be of service, a sharp, porous soil that can be made firm without caking or setting is the ideal. Bone meal, hoof parings and horn shavings, chalk (where soil is deficient in lime), and soot are the best substances to dig into the ground before planting, but the greatest benefit will accrue from liquid manure applied at frequent intervals from the time the flower spikes begin to show themselves, and if either fowl manure or pigeon manure is available, nothing better could be for making the liquid manure. Be cautious in regard to the strength at which it is applied.

LIMESTONE

ROCK GARDENS built of local stone are often lacking in effect due to the stone rather than the building. It is only necessary to see our weathered limestone collected on the Fells to realise its beautiful effect. Each stone is a rock garden in itself.

We have the sole agency for the surface stone of a large estate in Westmorland and will load in trucks at 25/- per ton. Six tons will make quite a fair sized rock garden. We shall be pleased to help with advice and plants, now is the time to build.

THE BARNHAM NURSERIES, Ltd., BARNHAM, SUSSEX.

Digitized by Google

Varieties are becoming so numerous that selection is just a matter of personal preference, but some sorts are of superior form, habit, or flowering capability, and are for such reasons outstanding as the best of their colours.

MONARCH is unquestionably the finest crimson, indeed, there is scarcely another of any colour to equal it.

ADMIRATION is charming for those who like bicolor varieties, the red standard and yellow frill being of clear glowing tones.

RADIANCE is the brightest and most fiery of the flame reds and is of medium height.

SILVER QUEEN is a favourite of mine on account of its fine size and perfect form, but some people do not admire its mauve tints. Others are lavish in their praises.

CARMINE KING is the best of the brighter-coloured, pure selfs, one shade of carmine throughout.

PEACE is delightful as a delicate flesh pink on fairly dwarf, compact plants.

SYBIL ECKFORD, PEACH BLOW, PRIMA DONNA and CAPTIVATION are among the best of those which have blended and suffused tints.

A. J. MACSELF.

GOLDEN PIPPIN APPLES

IT may surprise many readers to see that there are eleven varieties called "Golden Pippin," though the name has a very attractive sound. If one reads up the authorities, one finds, for instance, Franklin's, Hughes', Pine, Pitmaston and Frogmore, each with the appendix "Golden Pippin"—though, as portrayed, they all appear dissimilar.

The true Golden Pippin, known under eight synonyms, is of great antiquity, the variety having been known in Evelyn's day, who stated that the Lord Clarendon cultivated it, but only as a cider Apple, for in his statement he says: "at Lord Clarendon's seat at Swallowfield, Berks, there is an orchard of 1,000 Golden and other cider 'Pippins.'" Evidently, in those days, Berkshire made cider cup, as well as Somerset, Hereford and Glorious Devon.

Evelyn also comments as follows: "About London and the southern tracks, the Golden Pippin is esteemed for the making of the most delicious cider, most wholesome and most restorative, but amongst apple Growers, the Golden Pippin is noted also for its crisp, juicy sugary and refreshing properties as a Dessert fruit" etc.

It makes a compact bush, although the only trees I have seen are compact orchard trees. I have been told, however, that it fruits itself out of existence on the dwarfing stock.

The fruit is small, roundish, inclining to oblong, the skin deep yellow, assuming a deep golden tinge when perfectly ripe, and strewn with russet dots. The origin of the variety is unknown, but it is stated by old writers to have been raised at Padham Park, near Arundel, Sussex.

SCARLET GOLDEN PIPPIN is a delicious Apple, and to my mind equal in its season to Cox's Orange Pippin. It may be used from January to May. The skin is bright crimson, shaded deep yellow, strewn with small russet dots and light-coloured specks; the flesh deep yellow, crisp, sugary, juicy and sweet, with a pleasant aroma. This is a really fine late dessert Apple and ought to be extensively cultivated. It should succeed either as an espalier, cordon, bush or half-standard tree.

FRANKLIN'S GOLDEN PIPPIN is an excellent mid-season variety which was well known over a century ago, and although it will not keep long after Christmas, it is, nevertheless, a dessert Apple of real excellence. A dwarfing stock suits it best The skin is deep yellow with rich russet shadings, the flesh yellow, tender, juicy, sugary and crisp, with a pleasant aroma.

HUGHES' GOLDEN PIPPIN is a rich yellow coloured Apple with green and russety dots, and about right in size for dessert. It is a fruit of first-rate quality, with yellowish white, firm, juicy flesh, sugary and aromatic. It is in season in January and February.

PINE GOLDEN PIPPIN is a dessert Apple which keeps its flavour until November. It is a small fruit with yellowish flesh, which is tender, juicy and sugary, and possesses a distinct pineapple flavour. The skin is covered with a coat of brown russet and marked with light grey specks; the fruit roundish and somewhat flattened, with blunt ribs, making it uneven and irregular in outline.

PITMASTON GOLDEN PIPPIN was raised by a Mr. Williams of Pitmaston in Worcester. Although a first-rate dessert Apple, it has never been much in demand, probably owing to its rather rough covering of brown russet and the somewhat squat form of the fruits. The flesh is deep yellow, crisp and tender, juicy, sweet and of rich flavour. The variety does well on the dwarfing stock.

FROGMORE GOLDEN PIPPIN was raised by a Mr. Ingram at the Royal Gardens, Windsor, and is at its best during November and December. The fruit is small, with a knob at the stalk, such as one sees in Newton Wonder or Lemon Pippin. The skin is yellow with a pale red cheek, streaked with crimson, the flesh yellowish, crisp, sugary and briskly flavoured. This is a pretty Apple, but one not generally known or grown.

TAUNTON GOLDEN PIPPIN is a medium sized dessert Apple coming into season from January to March. The skin is deep rich yellow, dotted with russet on the shaded side, patched with red and streaked deeper red on the side next the sun, eye open, stalk short, flesh yellow, firm, crisp, sugary, with a rich vinous flavour.

SUMMER GOLDEN PIPPIN is an early delicious Apple becoming fit for use about the middle of August and succeeding remarkably well on the dwarfing stock. The skin is yellow, orange and brownish red, spangled with russety dots, the eye open, stalk thick, flesh yellowish, firm, juicy and sugary; altogether a desirable summer Apple.

SCREVETON GOLDEN PIPPIN is a variety well known in Nottinghamshire, where it was raised in the gardens of Sir John Thoroton about the year 1808. Fruit small and of first-rate quality, skin greenish yellow with russet patches and dots, eye open, stalk ¼in. long, flesh yellow, crisp and sugary.

CLUSTER GOLDEN PIPPIN—known also as Thick-set and Twin Cluster Pippin. This variety is more ornamental than useful. It certainly makes a pretty feature in the shrubbery. The fruit is small, the skin yellow and orange with a network of thin grey russet.

The outstanding variety of those mentioned is Scarlet Golden Pippin, which is worthy of extended cultivation. GEORGE LOVELOCK.

Iris lacustris.—This miniature North American Iris is so hardy and so delightful in the rock-garden, especially in the moister places, that it ought to be much more frequently seen. One more often meets with the bigger but very beautiful I. cristata, but most of us have room in our gardens, as well as in our hearts, for the exquisite little I. lacustris. It may be described as a miniature I. cristata, with all its beauties, but of a deeper blue. A well known writer speaks of it as of powder blue and gold, and the description is not far astray. It is a truly charming little plant only two or three inches high, creeping over the ground with its small rhizomes and flowering freely in summer. In cultivation it is quite easy, but it is sometimes lost when the plants are but small by reason that slugs, which have a penchant for novelties, may crop it to the ground when it is making growth in spring. They do not appear to trouble it much, however, when there is a little clump, for then the novelty has worn off and they leave it alone. In nature it grows near the margins of some of the North American lakes, where it favours gravelly soil, but it is not exacting in this respect and will flourish in loam and sand or grit. It likes a fair amount of moisture, and in drier places may be treated to partial shade by way of compensation. Plants may be procured in spring from hardy plant nurseries in this country.

Viburnum rhytidophyllum.—Among the swarm of Viburnums now in cultivation from China and elsewhere, none stands out more distinctly than this. Its individuality is due to the remarkable wrinkling of the leaves. A native of Central and Western China, it was introduced in 1900, and has hitherto proved quite hardy in the open ground, although in bleak, exposed situations it has a rather woe-begone aspect during a cold spell. Under the showers and warmth of spring, however, it quite recovers. The flowers are dullish white and not particularly attractive, but its fruits are extremely handsome, being oval and about one-third of an inch long, changing at first to coral red, finally to black. They are at their brightest in September, when, in association with the large wrinkled leaves, they impart great distinction to this shrub. The largest leaves are 7 inches or 8 inches long and up to 3 inches wide, dark glossy green above, covered with a soft grey wool beneath. It has the curious habit of forming its inflorescences in autumn; the flower-buds remain exposed all through the winter, expanding normally in spring. The shrub is vigorous in growth, and assumes a shapely form. It is increased by cuttings placed in gentle heat.

Viburnum Davidii.—This also is a very distinct Viburnum, as well distinguished, in fact, from the older species in gardens as is the preceding one. Both are evergreen, but otherwise have little resemblance, V. Davidii forming a close, rounded or hemispherical bush, apparently not more than 2 feet, or perhaps 3 feet high. The most striking features of the foliage are the three conspicuous veins that start at the base of the leaf and run lengthwise to the point, the leaves being leathery, 2 inches to 6 inches long, about half as wide and very dark green. The flowers are dullish white, one-eighth of an inch in diameter, and thickly packed in an inflorescence 2 inches to 3 inches across. The fruits are slenderly egg-shaped, a quarter of an inch long and blue. That well known collector, Mr. E. H. Wilson, introduced it to the Coombe Wood Nursery in 1904. There is a demand for neat, dwarf evergreens of slow growth, such as this Viburnum, for rock gardens; they relieve the bareness in winter and furnish a setting for the flowers in spring and summer.

Answers to Correspondents

THE GREENHOUSE.

CYCLAMENS AND BEGONIAS ATTACKED.—(W. O. B.).—The grubs are those of the weevil Otiorrhynchus picipes. They devour the roots of many plants, especially of those with fleshy roots. The best treatment is to turn the plants out of their pots and pick out the grubs. Later on, about April, the grubs turn to beetles, which eat the foliage of ferns and other plants and the shoots of vines. These may be captured by shaking the plants, *after dark*, over a piece of paper, or by putting down old sacking for them to hide in during the day.

THE GARDEN

No. 2724.—Vol. LXXXVIII.] [February 2, 1924.

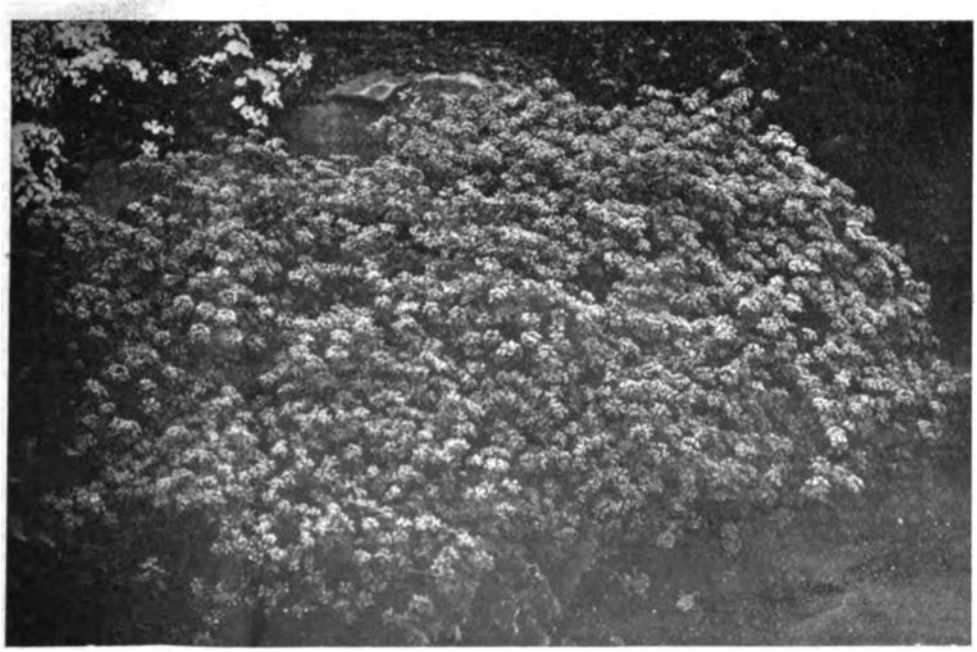
It was intended to have instituted several alterations in this number; owing to the railway strike these are postponed until the issue of February 16th.

RECONDITIONING THE ROCK GARDEN

THE Editor invites me to write on the remaking and replanting of rock-garden pockets, and the trimming of the plants which occupy them. He says that the subject is not an easy one. He is right; but I think the trouble arises less from any inherent difficulty in the processes involved than from the fact that it is a thankless as well as a fruitless task to attempt to lay down general rules to cover a wide range of varying conditions, whatever the subject be. If you know what sort of soil and situation you are dealing with, and what kind of climate you possess, then an elementary knowledge of gardening and a little common-sense will leave no formidable problem to be solved. But how can one prescribe at the same time for clayey, sandy and peaty soils? For the climate of Sussex, Devonshire and Lancashire? For the rainfall of Essex and North Wales? But before coming to these practical questions, there is an æsthetic one on which I should like to offer a few comments, as it is bound to govern our operations to a considerable extent. The question is fundamental, and is simply this: What are we aiming at? In other words, what kind of rock garden is our ideal? There is quite a wide divergence of opinion and of practice in this matter. The trained professional gardener, turned into the rock garden, will instinctively wish to introduce into it some of the orderliness which he associates with good gardening. He will, generally speaking, not approve of one plant invading the territory of another, and a "mixed grill" of three or four species all intertwined will not appeal to his palate. He will tend to confine each plant or clump to its own domain, as one does in the herbaceous border, and in replanting a pocket or slope he will dot a number of young plants evenly over its surface. The gardener, on the other hand, who is also a traveller, to whom alpine and rock plants recall the glorious prodigality of growth and bloom on the Pyrenees or Alps or Carpathians, will place less store on neatness. A tangled mass hanging over a boulder may give him a thrill when the best workmanship would leave him cold, and a happy riot of half a dozen harmonious species, recalling with a "pleasure that's all but pain" the alpine meadows of the Val di Fain or Pilatus, will appeal as the best work of scissor and trowel could never do. This antithesis was well exemplified a few years ago in a correspondence in a gardening contemporary, which some of my readers will remember, which followed on a criticism by an eminent gardener, residing within fifty miles of Waltham Cross, of a famous rock garden, situated within the same distance of Kingston-on-Thames. There is a good deal to be said on both sides. It all depends on what you want. Probably most rock gardeners prefer a middle course. In any case, there are certainly some plants which, if they are to look well and happy in the rock garden, need drastic treatment, and others that should be carefully left alone.

Well, first as to pockets. If your natural soil is light and porous, it should keep in good condition for a long time, and, of course, the same applies to good made-up stuff used where the natural soil is unsuitable. Some of the pockets at Kew have not been renewed for thirty years, and still do not need it, despite the fact that smoky atmosphere and sooty rain, due to proximity to London, tend to produce atidity of the soil. Porous material and very thorough drainage help to keep the ground sweet. A word may be said against the plan (used at first, I believe, at Wisley, only to occasion subsequent regret) of building the rock garden first, and subsequently digging out the pockets and filling them with good material. Better make a proper job of it at once. Many rock plants have a remarkable root-run —several yards in some instances—and to surround them with a wall of inhospitable material is to handicap their full development. Besides, many delight to get their roots well under the rocks, where the soil tends to be drier and warmer in winter, and cooler and moister in summer.

Of course, if pockets are being replanted, the opportunity should be taken to dig them thoroughly and enrich the soil a little with leaf-soil, sand



A YELLOW-FLOWERED TRAILER, ALYSSUM SERPYLLIFOLIUM.
Alyssums are not long-lived, so should be renewed periodically.

Digitized by Google

if the ground seems heavy, lime if it seems sour, and in some cases (on sandy soils, for instance) a little thoroughly rotted manure. An annual top-dressing with fine leaf-soil and sharp sand is useful in all cases; but on the whole, if there is deep drainage and good light soil, this should suffice for many a year, and the plants themselves will give warning, by their want of vigour and of crispness, when a change is required.

As to the amount of trimming, etc., to be done in autumn or spring, tastes vary, as I said at the beginning. But without doubt, while some plants look best as a separate clump, others, notably many of the carpeters, are singularly pretty when allowed to intermingle freely—to marry each other, as Mr. Burbidge used to call it. You can get the quaintest effect by allowing things like Acæna microphylla with its crimson fruit-heads, the grey-green A. Buchanani, Cotula squalida with its brownish tint, Arenaria balearica covered with little white stars, prostrate Thymes, and so on, to intermix as pleases them; by doing this, of course, you lengthen considerably the flowering period of the carpet.

Among the plants which should not be disturbed at all are dwarf shrubs, such as the prostrate cotoneasters and willows, those with long woody roots (in their native haunts mostly found on dry, poor soils) such as æthionema and potentilla and astragalus and coronilla and fleshy tap-rooted plants like eryngium and most gentians, and some statices and campanulas. Save for the autumn "bedding-up," these are better left alone, both above and below ground. On the other hand, we all realise that many of our best known rock garden plants—arabis, aubrietia, alyssum, achillea, rock-roses, pinks, at least all the larger species of them—need a good hard cutting-back to keep them from looking untidy and unnatural—for in their native habitats, under more rigorous conditions, they grow neat and crisp, and do not straggle or "flop"—to use poor Reginald Farrer's favourite word. Other plants, again, such as many of the Mossy and Kabschia saxifrages, enervated by a too mild climate and a too rich soil, tend after a few years to die off in the centre of the cushion. With the Mossies, which root very readily, we have only to remove the whole clump, dig over the pocket, and replant in small pieces. The Kabschias, being slower to root, it is better to replace the old tufts with young plants struck a year earlier in a cold frame. Often a new lease of life can be given to such a cushion by simply top-dressing and then dumping down a stone on the dead portion. The stone provides protection and encourages growth, and is soon fringed with healthy verdure.

Many of the small shrubby plants, such as Hypericum olympicum, H. Coris, micromerias

THE ROSE-FLOWERED DIANTHUS CÆSIUS GRANDIFLORUS.
The larger-growing Dianthi are improved by topdressing.

SAXIFRAGA BURSERIANA IN A ROCK CREVICE.
Now is a good time to topdress the Kabschia Saxifrages with a gritty compost.

of sorts, Spiræa Hacquetii, and so on, die back a long way, and need hard cutting, but this should not be done too soon; leaving the fruit encourages seeding, and the dead rusty brown stems are not without beauty in the autumn, when the rock garden lacks interest so sadly. But even here we should be a little cautious. If we cut a santolina, for instance, hard back, it will make in the following season a fine round grey bush, but no flower, for it flowers on the second-year wood from the leaf-axils of the preceding season; but the second year after cutting it will bloom better, probably, than it ever did before.

As to the time at which these operations should be carried out, there is no secret or mystery; once summer is over, work can begin, and continue throughout the winter: but planting and replanting are best done in autumn, since better growth will result in the following season than if one delays till spring is approaching. In a backward season like the present one, however, planting may still be done with a prospect of a good flowering season to come.

R. LLOYD PRAEGER.

FOTHERGILLAS AND PARROTIAS

THE hamamelis family, to which the fothergillas and parrotias belong, is not a very large one, but it includes some very interesting and attractive plants, for, besides hamamelis, fothergilla and parrotia, it comprises liquidambar, corylopsis and distylium, all well worth representing in any garden. Fothergilla consists of three, perhaps four, species, all from the south-eastern United States, and the name commemorates Dr. John Fothergill, a Quaker physician, well known to gardeners and botanists in the late eighteenth century through the fine collection of hardy trees and shrubs he cultivated in his garden at Upton in Essex. A curious feature of the fothergillas is the absence of petals from the flowers, the beauty of which is solely in the numerous long stamens arranged more or less in bottle-brush fashion. They have one other great attraction in the fine coloration of the foliage in autumn, all the species being notable in this respect. These notes, indeed, have been suggested by seeing, in Sir George Holford's fine arboretum at Westonbirt during late autumn, the newest and least known of the fothergillas (F. monticola) in rich red colour. F. major turns yellow or orange in autumn; F. Gardeni, beautiful crimson. The oldest and for many years the only fothergilla in cultivation was

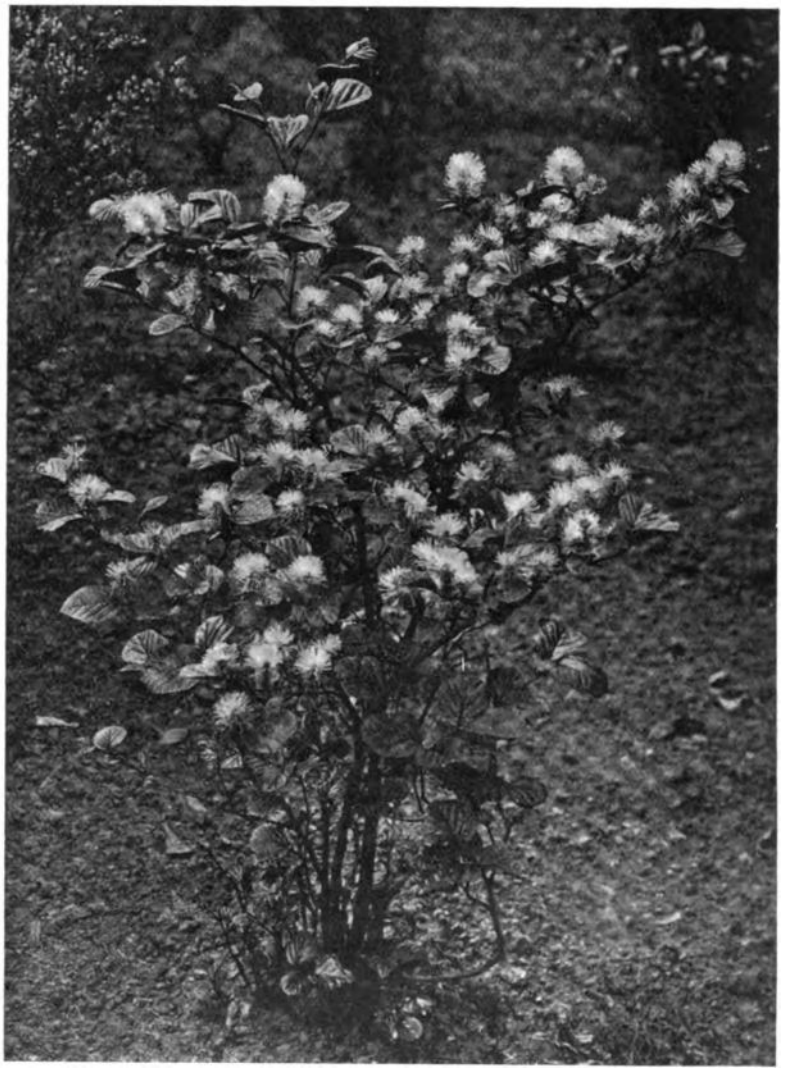
F. GARDENI. It was introduced in 1765, but has never been common, nor, as a matter of fact, is it so now. It is a shrub of rather weak habit which is rarely seen more than two or three feet high, with heart-shaped or ovate leaves 1½ins. to 2½ins. long. It blossoms in April and early May, the stamens being about half an inch long, white with yellow anthers, and forming a globose or cylindrical cluster 1in. to 1½ins. long. It is quite pretty at this time, and the fragrance of its flowers adds to its charm. But, after all, it is its beauty in autumn, perhaps, that will recommend it most strongly, the leaves varying in hue from rich crimson to scarlet. It is not a vigorous shrub; if it were it would be commoner than it is. But of its capacity to withstand cold there is no doubt; it succeeds in the Arnold Arboretum, Mass., where they have, occasionally, forty degrees of frost. It likes a sunny, sheltered spot, and a lightish loamy soil or one of a peaty nature seems to suit it best. This shrub is known in gardens frequently as F. alnifolia, and a new name, F. carolina, has been concocted for it in America.

F. MAJOR is a much more robust and more easily cultivated shrub and grows up to 8ft. in height. It was cultivated in this country more than one hundred years ago; but was lost sight of until about twenty years ago. It is one of the shrubs whose re-introduction we owe to Professor Sargent and the Arnold Arboretum. When freely in blossom it is very attractive, being covered with its cylindrical clusters, up to 2ins. long, of white stamens. The leaves are roundish or roundish oval, rather glaucous beneath, usually obliquely heart-shaped at the base and only slightly toothed towards the apex. On the whole, although not so noticeable in autumn as F. Gardeni, it is a better shrub for gardens. There is a large group of it near the Palm House at Kew.

F. MONTICOLA was first recognised as a species by the American botanist, Mr. W. W. Ashe, in 1897, but continued to be confused with F. major. Both the distinguished dendrologists, Mr. Rehder and Dr. Schneider, at first considered it as not being specifically distinct from F. major. Not having then seen the living plant, and following them, I made the two species synonymous in my book on hardy trees and shrubs, published in 1914. The plant is now in cultivation at Kew, Westonbirt, Aldenham, and no doubt in several other places, and is easily distinguished from F. major by the leaves being much more conspicuously toothed towards the end, green (not glaucous) beneath, and by their turning red in autumn. Also, the branches, erect in F. major, are open and spreading in F. monticola. The flower clusters appear to be very similar and equally ornamental. It is found wild in the south-eastern United States from North Carolina to Alabama, and is apparently quite hardy, growing 6ft. to 8ft. high.

American botanists distinguish a fourth species, F. parvifolia, which appears to be very near F. Gardeni, differing in the more rounded leaves toothed from the apex to the middle, and in the shorter stamens. It may be in cultivation, but I have not distinguished it.

All these fothergillas can be propagated by cuttings made from firm leafy twigs in July and August. They should be put in very sandy soil in a mildly heated close frame.



FOTHERGILLA MAJOR.

An attractive species with cylindrical clusters of white stamens.

Turning to the parrotias, of which two species are known, we find that they differ from the fothergillas in being trees, although not large ones, and they are also natives of the Old World. The better known of them is Parrotia persica, which was introduced to Kew in 1841 and is found wild in Persia and the Caucasian region. Growing to between 30ft. and 40ft. high, it has wide-spreading horizontal branches that give it a very picturesque appearance, and a stout trunk from which the bark peels off like that of the plane. The flowers

Digitized by Google

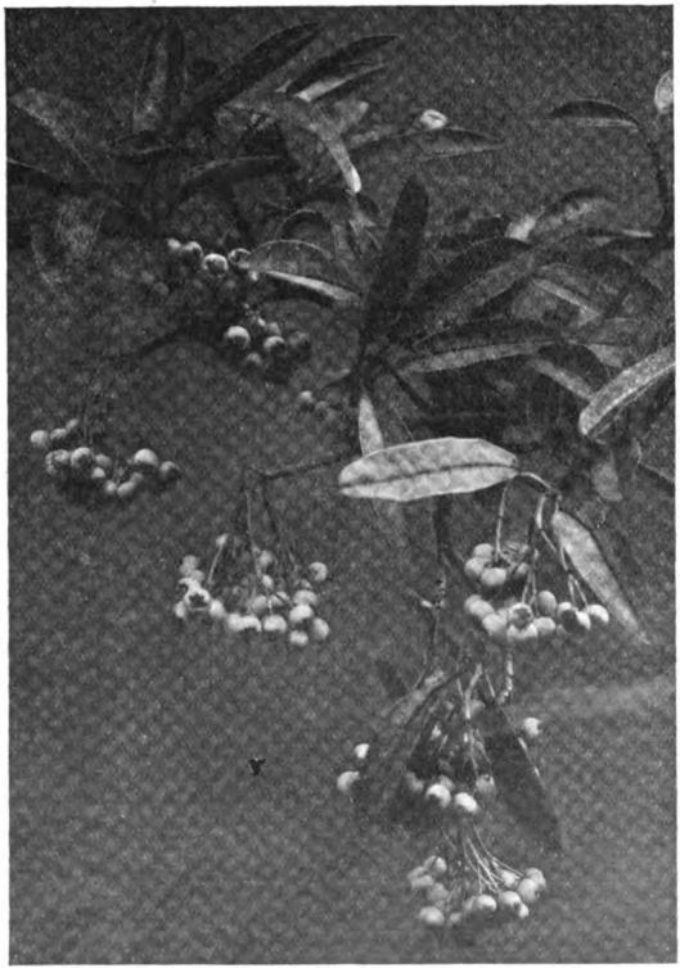
usually appear in March, sometimes earlier if the weather be open and mild, and although individually small, they are extremely abundant. They appear on the leafless twigs in clusters ½in. across, and, like the fothergillas, have no petals, the only conspicuous part of them being the red stamens. When well in blossom a tree gives a pleasing effect, especially when seen from a short distance away during sunshine—a curious, haze-like glow of red.

This tree is well represented in Sir George Holford's collection at Westonbirt and does its part in producing the wonderful pageant of autumn which is, perhaps, the most outstanding of the varied fascinations of that great garden. The foliage dies off in beautiful tints of crimson and gold.

P. Jacquemontiana, the other species, is a much smaller tree than the Persian one and only half its height. It is a native of the Himalaya, especially in Cashmere, and although known since 1836, when it was discovered by Dr. Falconer, it was only introduced in 1879, in which year seeds were sent to Kew. Like P. persica, it has no petals, but it has one great distinction from that species in the large white bracts which accompany the flowers. In P. persica these bracts are small and brown; in P. Jacquemontiana they are petal-like and ½in. to 1in. long, giving the same appearance as a white flower with a large cluster of yellow stamens in the centre. Of all the species mentioned in these notes this is the least effective in autumn. Naturally, the leaves would appear to turn yellow if they had the chance, but they remain fresh on the tree so long in our climate that before they have time to acquire the natural tints of slow decay they are battered by the wind, rain and frost. Both these trees are hardy in the home counties, but, no doubt, P. persica is the hardier and more desirable. They like a good loamy soil and a sunny spot. W. J. BEAN.

NEW AND RARE SHRUBS

ARUNDINARIA MURIELÆ.—The impetus given to the cultivation of hardy bamboos by the publication of the late Lord Redesdale's book, "The Bamboo Garden," in 1896, has slackened somewhat in these latter years. We are now able to judge which are really worth a place in the ordinary garden and which are better kept out of it. While some of the best bamboos are still unequalled for vegetative grace and beauty, others are apt to develop into unmitigated nuisances. Among the latter is the one we used to grow as Arundinaria pygmæa, which Mr. Gamble has lately named A. vagans. Nor, in any garden where I had a tree hand, would room be found for AA. Veitchii, angustifolia or humilis. The work entailed in keeping such species within proper bounds is not sufficiently repaid by their none too obvious attractions.



THE NEW RED-BERRIED STRANVÆSIA SALICIFOLIA.

But I believe one can safely prophesy that this new species, introduced from Western Hupeh by Wilson, will secure a permanent place in cultivation. One can give it no better testimonial than to say it is allied to A. nitida and that it promises to rival it in beauty. It has the same luxuriant leafage, the same grace, the same crowded cluster of stems arching outwards at the top, but the stems (purple-black in nitida) become rich yellow in Murielæ, the sheaths that partially clothe the younger ones are straw-coloured and the leaves are rather larger. So far as one may judge from its behaviour during the few years it has been growing in the open air, it is hardy. Wilson found it in 1907 up to 10,000ft. altitude in Hupeh growing from 6ft. to 13ft. high, "with its clear golden, slender stems, one of the most beautiful of Chinese bamboos." A small plant in a pot was introduced to Kew in 1913 from the Arnold Arboretum, which, after being nursed in a greenhouse, was ultimately planted in the open ground and grew luxuriantly. Mr. Gamble named it three years ago after Mr. Wilson's daughter, Muriel.

ROSA MIRIFICA.—This is a new and interesting rose from the south-western United States which was introduced from the Arnold Arboretum to Kew in 1917. It had been collected the previous year by Mr. Rehder on the Sacramento Mountains in New Mexico at an altitude of about 6,000ft. Some twenty to twenty-five years ago a rose named R. stellata was discovered in the same State and has once or twice appeared in cultivation, but has proved difficult of culture. To this species R. mirifica is closely allied, but, fortunately, it is thriving quite well, and has proved a pretty shrub, very distinct from anything previously in cultivation except its relative. In habit it is lax and does not promise to be more than two or three feet high, the stems being armed with sharp slender spines ½in. long and furnished with gland-tipped bristles. The leaves are about 1in. long and made up of three or five leaflets, each of which is ½in. to ¾in. long, obovate, coarsely toothed and smooth. The flowers are solitary at the end of short twigs and of a pretty and distinct shade of pink, measuring 2ins. to 2½ins. in width. The globose ovary is thickly covered with pale spines like those on the young shoots but smaller; like the sepals, they persist on the ripe fruit. It flowers in July at Kew.

R. mirifica differs from R. stellata in having most frequently five leaflets to each leaf, whereas R. stellata has never more than three, also in the absence of starry down on the shoots to which the name stellata refers. It should have a place in full sunshine and can be propagated by the suckers it produces. Mr. Rehder considers it one of the handsomest and most distinct of American roses. Even in the Arnold Arboretum, he tells me, it is fairly hardy, so it ought to be perfectly so with us.

SMILAX MEGALANTHA.—Among evergreen climbers the smilaxes give a very distinct effect, for there is nothing quite in their way in this class of shrub. Their botanical relationship with the lilies is also remarkable. Many of the species have deciduous foliage, but two evergreen ones, SS. aspera and excelsa, have long been cultivated in England; but lately appear to have disappeared from cultivation. Wilson introduced several species from China, the most striking of which is Smilax megalantha. This also is evergreen and grows some 15ft. high, the stems being armed with irregularly scattered spines up to ½in. long and furnished with tendrils proceeding from the leafstalk. The leathery-textured leaves vary much in size and shape, but the largest—9ins. long by 6ins. wide—surpass in size the leaves of any hardy smilax; they are richly green above, glaucous beneath, and conspicuously three-nerved. The plant is worth growing for its foliage alone. Wilson describes the flowers as greenish (they are of no great beauty in this genus) and the fruits as globose and coral red.

It is a native of Hupeh, Western Szechuen and Yunnan, and was originally collected by A. E. Pratt and the Rev. E. Faber. Neither of them sent home seeds, and its introduction was reserved to Wilson who, in 1908, sent seeds under his number 661.

STRANVÆSIA SALICIFOLIA.—I first saw this shrub in the nursery of the Arnold Arboretum in 1910 and obtained from Professor Sargent a plant for Kew which I believe represents its first introduction to this country. It had probably been sent to America from China by Wilson during his 1907-8 journey. It is, no doubt, closely related to Stranvæsia undulata, another

Digitized by Google

of Wilson's introductions now becoming pretty well known and appreciated in English gardens, but is of taller, more robust growth and very distinct also in its oblong, longer and proportionately narrower leaves. It is evergreen and may possibly develop into a small tree, the young shoots being densely clothed with brown wool. The flowers are produced on downy-stalked terminal clusters 3ins. wide, in June, each flower ½in. wide with five round petals; the stamens have red anthers which give a pretty tinge to the cluster. The flowers, however, are too fleeting to count for much and the chief attraction of the shrub is in the fruits. These are globose, red without the orange shade seen in S. undulata, and about ¼in. wide, remaining on the branches until November and December. The shrub is evidently very hardy and, producing its fruits freely, promises to make an attractive addition to the garden in autumn. W. J. B.

A NEW HEDGE PLANT

Lonicera nitida supplies all the requirements for an evergreen hedge. It is completely hardy and of rapid growth.

LONICERA NITIDA so amply meets the chief requirements of an evergreen hedge plant in our climate that it is curious that it has not been widely adopted for that purpose. It reached us from China some score of years ago, but I did not come across it and get plants until 1912. It was then offered as a new and rare shrub at a price varying from 3s. 6d. to 5s., and so conservative are our nurserymen that these attributes and values have lingered in some catalogues to this day. In a catalogue sent to me by Messrs. Gauntlett fairly recently—this firm have the bad habit of not dating their publications—the claim of rarity is indeed, abandoned, but it is still termed a "dainty specimen bush 4-5ft. high"; and, although the description ends with the sentence, "if clipped it makes a fine hedge," there is no quotation by the hundred or even by the dozen, and single plants are charged 2s. 6d. and 3s. 6d. I claim that if a demand equal to its merits had been created by publicity, it ought by now to have been put on the market at the same price as the common privet, a claim based on my experience of it, which is as follows:

Obtained for Mounton House in Monmouthshire in 1912, the plants, treated as "a dainty specimen bush," were set in a shrubbery which, during the war years, was not overhauled. Indeed, there was little time for much rearranging and replacing until 1920, when, also, the propagation department regained some vigour. It was noted that Lonicera nitida was among the few evergreens that had escaped the 1917 winter unseared, that it had grown into bushes 6ft. high and as much through, and that far from being dainty it was an aggressive neighbour, dangerous to small or slow-growing plants from the self-layering habit of the bottom boughs. It was also found that layering was by no means the necessary form of propagation, but that cuttings put in a frame or even in the open rooted without a single failure and in a very short time. These qualities gave the idea that its real sphere was as a protective hedge, easily raised, of rapid growth and complete hardiness, upright in growth and with leaves so small that clipping did not give the effect of laceration. It was certainly worth the experiment, and some five or six hundred cuttings were put in. In May of 1921, just before the long drought set in, most of the old plants were found to be too expansive for their position among other shrubs and—in order that their half-smothered neighbours might suffer least in the process—were pulled rather than dug out. Each broke up into several, and all were set to form a screen in the wood garden far away from the possibility of watering At the same time some yews of equal age were removed with the utmost care from one situation to another a few yards away. They were screened, syringed and watered for months, and yet quite a third of them were lost. But, although some of the neglected loniceras died back somewhat, every one came through the ordeal, and in 1922 regained what they had lost. Meanwhile the cuttings had been set out in rows and grew apace, so that in the autumn of 1921 the hedge now illustrated was planted in a garden then in its inception and situated in an exposed spot 700ft. above the sea. On the other side of the path, and therefore beyond the left-hand edge of the illustration, young bush fruit was set, and between the rows, awaiting a final destination, what was left over of the loniceras were aligned. During 1922 the hedge was left to itself, but it was clipped both early and late last summer. It was after the second clipping that it was photographed, and it will be seen that it is already trim and shapely. When the photographer came the operation of removing the surplus loniceras to their permanent place was imminent and so one specimen was dug up, a 5ft. 6in. high man set next to it, and the camera brought to bear. Thus not only the erect habit and general characteristics of the plant are shown, but its height, with the ball of earth resting on the path, is seen to be higher than the man. When set in soil it measured just under 5ft. Have we any other hardy evergreen that will reach such a height within three years of being a twig on the parent plant? Its habit of not only sending up several erect stems, but also laterals springing from the root stock is well seen in the illustration, and some of these, having formed independent roots, were removed before replanting. Thus, anyone using three year old plants for hedge-making can get stock for a hedge of six times greater length in the following season. And as to cuttings, so keen on survival is every twig that the clippings of the late summer trimming, having been thrown on a rubbish heap, quantities of them were found to have rooted when the heap was turned over at the end of October. They were rescued by the man who appears in the photograph, who has set them as a future hedge round his cottage garden.

Although, surely, many others beside myself must have recognised its merits, I had not until last summer came across any use of Lonicera

LONICERA NITIDA.
A clipped hedge of plants three years old.

LONICERA NITIDA.
A single plant three years old.

Digitized by Google

nitida as a hedge plant except the one illustrated. But then I saw one at Mr. Eley's garden at East Bergholt in Suffolk, a garden with few equals for the variety and healthiness of its shrub collection. He had set the plants ten or more years ago to form a screen, intending to leave them to their natural growth; but they soon showed their trespassing character, and the shears were brought into requisition to restrict them to their own area. They are thus disciplined into an admirable hedge, stout, strong and dense, kept down to about 6ft. high and rather less through. Thus Mr. Eley has tested it for longer than I have, and that test establishes its many virtues, while—anyhow, so far—it has developed no vices. It flourishes alike in East Anglia and in the Western Counties.

SOME DESIRABLE ANNUALS

ONE of the pressing needs of the moment is the making out of seed lists, and it will, possibly, be helpful to draw attention to some good things that may generally be overlooked. There are a certain number of good annuals that may be advised for such a place as a border or bank in full sun—plants from California, Mexico and South Africa. Among them are some of the poppyworts—eschscholtzias, of which there are now such gorgeously coloured varieties, and Argemone grandiflora with its large white poppy-like flowers, much resembling those of Romneya Coulteri. This fine plant stands nearly 3ft. high, and the prickly-looking foliage is not the least part of its beauty. The Californian Bartonia aurea, more properly called Mentzelia Lindleyi, is a shorter plant. Arctotis leptorhiza has flowers of a fine orange colour and rises to about a foot in height. Dimorphotheca aurantiaca is another showy orange composite. Thunbergia alata is a trailing plant with dark-eyed cream and orange flowers that would suit the sunny front edge of the warm border. These last three plants are from South Africa. Arctotis and eschscholtzias may be sown in the open, and possibly bartonia, but the others should be raised in mild heat and put out in the first days of June. With the exception of the argemone they are all plants of strong, warm colouring that will make a fine show if planted in company. There is another desirable dimorphotheca, D. pluvialis, less suited to be planted with these, but a fine plant. The flowers are white, with the back of the petals of that pleasant quiet colour that is like diluted ink, such as one sees in that interesting plant Stobæa purpurea.

There are a certain number of annual plants whose small stature or neat habit makes them specially suitable for the rock garden or the top edge of dry walling, or anywhere where they are brought near the eye. Asperula azurea setosa is a charming little plant with lavender blue flowers, delightful in a still dwarfer setting of Alyssum maritimum; both are sweet-scented. Another little blue beauty, Anagallis cærulea, about 6ins. high, may well be in the same company; also Nolana prostrata and N. atriplicifolia, blue-flowered plants of prostrate habit, natives of South America, that can be sown where they are to flower. One hardly expects blue flowers from any stonecrop, but the little annual Sedum cæruleum certainly has a faint blue colouring. Grammanthes gentianoides, another tiny gem, sounds as if it ought to be blue, but the flowers are of a rich deep orange colour almost approaching that of the brightest mahogany. This and the sedum should be raised in pots and planted out just as they are, straight from the pots without any disturbance. Nycterinia selaginoides is a delightful little pale pink starry thing, so small that it would be lost on the level, but a wonder of form when seen close.

There is a splendid poppy that seems to be always forgotten, the tulip poppy (P. glaucum). The large flowers of deepest scarlet are among the most brilliant of its kind with its grand bloom and glaucous buds and foliage it is a more striking plant than P. umbrosum, which is more commonly grown. It is best autumn sown. The leptosiphons are good plants that are too much neglected; the rich colouring of the red and orange varieties have an effect of being diffused, from the small size of the abundant bloom. When once grown they appear again self-sown. They are not too large for places in bold rockwork.

The night-scented stock (Matthiola bicornis) is too often forgotten. It has no effect in the daytime, for the flowers are of no size and are of a

Photo, Sutton and Sons

THE BRILLIANT ORANGE DIMORPHOTHECA AURANTIACA

Digitized by Google

dull pinkish, brownish colour. They remain closed till dusk, but when the light is gone they open widely and freely exhale their delicious scent, and are quite the best of the night-scented flowers of the hardy garden. Platystemon californicus has flattish cup-shaped flowers of a pleasant cream colour, with a spreading habit something like that of the better known Limnanthes Douglasii. Both of these are best autumn sown, when a single plant will cover nearly a yard of space. Platystemon when once established comes again by self-sown seeds. Lathyrus sativus is a pretty little blue pea of mildly climbing habit, about two feet high; it may be sown in place. The better, purplish blue L. pubescens will grow 4ft. high or more, but is tender and perhaps hardly to be classed with annuals. But the gem of all climbing plants is the splendid Ipomœa rubro-cœrulea. It should be grown in heat and planted out in June. It is usually seen in a greenhouse, but in a fairly warm summer on a south or west wall, its wonderful and perfect blue is a sight to see. The deep purple blue and a lighter tint of the same, of a good strain of the old Convolvulus major (Ipomœa purpurea), are also fine things; they are rampant climbers, up to seven or eight feet. A beautiful climbing annual that was in much favour fifty years ago is Maurandia Barclayana. It is raised in heat, potted off singly and put out in June. The foliage is delicate, and it has pretty purple flowers shaped something like a pentstemon; it should have a place near or against a warm wall.

Among annuals of large size there is the fine old Lavatera trimestris, with flowers of a good pink. There is also a so-called improved variety of a deeper colour, dangerously approaching an unpleasant quality of rankness. It is a case of progressing backwards! But another variety called Loveliness, also of a stronger colour, is without this taint. The pure pink lavatera groups charmingly with white cosmos, also a plant of some height. The habit of cosmos inclines to be straggly, but it can be bettered by stopping the growth at least twice, when it assumes a bushy habit and gives more bloom.

Biennials are usually associated with annuals, and one may mention the usefulness of the purple rocket and the darker kind of purple honesty (lunaria). The two plants are much alike, both in colour and habit, and are of great use in the back regions of any garden scheme of which the time is the month of May.

To return to true annuals, salpiglossis should never be forgotten. The tall kind is the best. The colourings of gold and mahogany, crimson and purple, all tone well together.

The tall African marigolds are indispensable in borders in the late summer and autumn, the best being the orange and the primrose coloured: the latter being a much better colour than the one of an intermediate yellow that is sold as lemon. Where there is a rather large space that it is desired to fill for the summer, the annual daturas, D. ceratocaula and D. cornucopia, are grand plants for the purpose; a single plant requiring four or five feet of space. Towering above and behind these, or in any other open space among shrubs, where something tall and large is required, the 8ft. high balsam, the white variety of Impatiens glandulifera, sometimes sold under the doubtfully correct name of I. Roylei, can be recommended. GERTRUDE JEKYLL.

FORTHCOMING EVENTS.

February 5.—Royal Caledonian Horticultural Society's Meeting, —— Croydon Horticultural Society's Meeting.

CULTIVATION OF THE GLOXINIA

CULTIVATION can be taken to mean the sprouting of the tubers which flourished last year or the raising of fresh plants from seed. First let us take raising from seed. And, before we set out upon purely cultural directions, it cannot be too strongly emphasised that strain counts, and so you will be well advised to procure your seeds from a reliable firm. With so important a flower, you are not likely to obtain poor seed if you pay a fair price for it—and a fair price is from 3s. 6d. per packet. Such firms as Messrs. Sutton, Carter, Blackmore and Langdon and Webb have strains that are above criticism, while the name of Peed and of Kelway's "Model" are so notably "specialist" that their excellence makes it impossible to arrange them in any sort of "order of merit." In whichever direction your choice may fall you are certain of the best, and that means a noble display of richly varied velvety flowers which expand for weeks in succession: with broad deep green leaves as a setting, and stiff erect stems that enable you to gaze right down into the centre of the flower and appreciate to the full the marvellous beauty of throat, stamens and stigma.

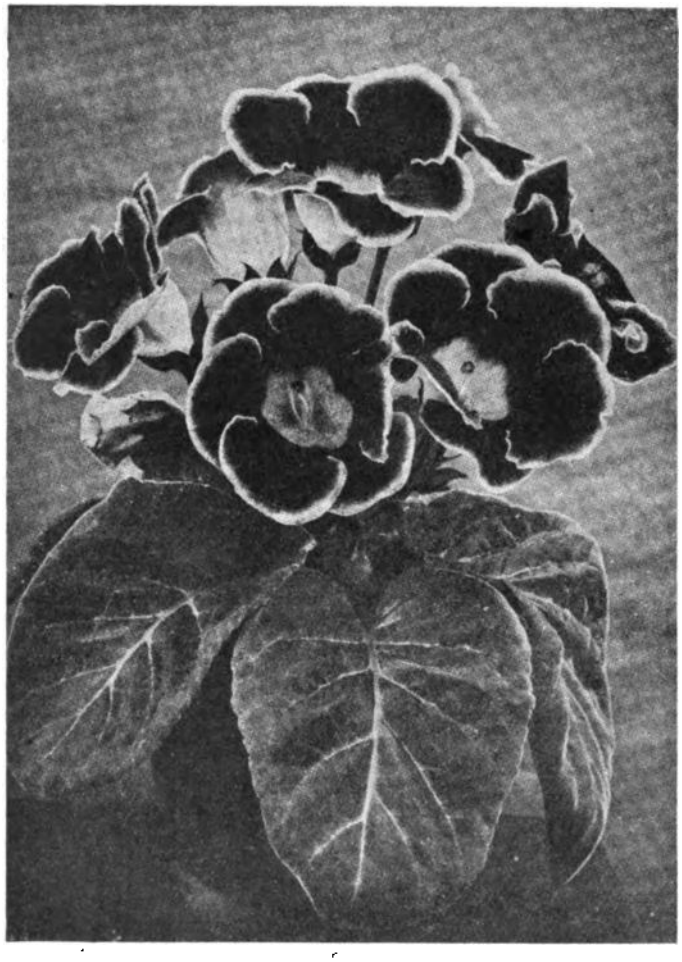

Photo. Blackmore and Langdon.

A GOOD TYPE OF GLOXINIA.

Gloxinia seed—when you open the packet—never fails to impress you as horribly expensive, there does look such a small amount of it: but, if one seed be separated out with the point of the penknife from the bulk and you then consider the size and quality of plant that it is going to produce, you will realise that the value is there. This brings us to the first point—thin sowing, no easy matter with such minute seeds. Personally I always follow the time-honoured dodge of mixing the seed with an equal bulk of fine silver sand, which enables thin distribution to be effected fairly easily. The best kind of sand to use is that supplied by the grocer for scouring purposes. It is not only very fine, but white, so that, in the dark soil, you can *see* just how thickly the sowing has been done. Consideration of the minute size of the seed and its even distribution leads naturally to the question of the most suitable kind of soil in which to sow this. A mixture of fibrous loam, peat, coarse sand and a small amount of leaf-mould cannot be bettered, and, in addition to thoroughly mixing these, the result should be sifted finely.

Shallow seed pans are the best receptacles, and, over the drainage hole, one large slightly convex crock should be placed, with several smaller ones upon the top of this: for no question must arise as to the efficiency of the drainage. Over this, fill the pan to within an inch of the top with the coarser part of the soil, finishing off with half an inch of the finest compost. Press this down firmly and then water through a fine-rosed can and set aside for a couple of hours to drain before sowing the seeds. It is possible to cover with the merest sprinkle of fine soil after the seeds have been sown, but I prefer merely to scatter on the surface and then to place a pane of glass and a sheet of brown paper on top. The glass prevents undue evaporation, the brown paper ensures that darkness which is essential to germination. Place the pans in a steady temperature—65° to 70° Fahr.—and see that the soil is kept evenly moist. The glass should be reversed twice a day to dispel condensation and prevent drip, and it will be some time before any further watering will be necessary. When it is, the water should be tepid, and the safest method of applying it is by standing the pans to half their depth in a pan and allowing capillary attraction to draw the moisture upwards until the surface has been thoroughly moistened. Allow the temperature to fluctuate as little as possible, and keep a sharp look-out for those tiny shoots which show that the seeds have germinated.

Directly germination is observed, you should dispense with the brown paper and allow the light to reach the seedlings: but light only, not direct sunshine. These wee seedlings are very easily injured by those bursts of spring sunlight that are so usual as the days grow longer. Nothing could provide a better demonstration of the

Digitized by Google

advantages of thin sowing than those healthy little plants which result where it is *not* necessary to prick off until the seedlings have gained some size; but if you should find that, here and there, sowing has been done too thickly, it is better to prick out a few of the crowded plants and transfer them to other pans rather than allow them to crowd each other. These transplanted seedlings need care in handling; the main point towards success being to make quite sure that the soil is pressed into contact with the tiny roots on all sides. In all cases, the plants should be given single pots as soon as the leaves are half an inch long. Use a similar compost to that which was advised for seedlings, but without sifting.

When potting, care should be taken to finish off the soil so that the surface is slightly convex, with the plant upon the top: water will not then lodge in the crown, and care should also be taken not to bury this. Keep the atmosphere humid and the temperature even and grow on steadily in a good light, but always using the blind while the sun is shining. Atmospheric moisture is best ensured by damping the floors, etc., several times a day, taking care, however, never to wet the foliage of the plants themselves. There can be no question that they grow fastest and do best when stood upon a closed staging, covered with shingle or ashes. Close warm humidity, indeed, is *the* secret of rapid growth of seedlings, but sufficient air should be admitted to keep the atmosphere fresh and prevent a stuffy feeling.

By the end of May or some time in June the plants will be ready for 5in. pots and, when they have filled these with roots, buds will begin to appear. Through the summer, take care that the plants are never crowded: each one should have sufficient space for those broad leaves to curl over the rim of its own pot without touching its neighbour, so that air can circulate freely between them. Seeds may be sown in January, February or March, according to the temperature at command—though it may be remarked in passing that splendid batches of seedlings can be raised at an early date, by the aid of a propagating frame. Maintain the plants in this frame until the temperature of your house has risen by the aid of the sun, etc., then gradually give more air and remove them to the staging of the house.

Where a stock of tubers—grown on from previous years—has to be started, February and March are the best months for doing this: although, where very early flowers are wanted, a few tubers may be placed in brisk heat soon after Christmas. The later period is the best for the main batch, following up—where late flowers are desired—with a small batch that has been kept cool in April. The initial procedure is the same in every case, and consists in embedding the tubers level with the soil in shallow boxes filled with light soil. Place these in brisk heat and keep the soil moist by regular overhead sprayings; but take care that this is not excessive, so that the soil becomes sodden and the tubers are constantly covered by beads of water. Directly top growth begins this spraying should cease and the soil only be watered. Do not allow top growth to advance too far before the tubers are placed in single pots or the roots will become entangled and cannot be separated without damage.

Pots double the size of the tubers should be used, while the drainage should be very perfect. Make a compost of equal parts of fibrous loam, peat and well decayed manure, with enough coarse silver sand to make the whole feel gritty. The tubers should only be just covered with soil and, until growth becomes active, only moderate supplies of water are needed, increasing this as the growth develops. Keep near the glass and observe precisely similar conditions to those advised for seedlings. At the end of a couple of months, large tubers should be given larger pots and (with those that are four or five years old) truly amazing results can be produced. A plant bearing 130 blooms, expanded at one time, is not an impossibility under good culture; and four or five such plants, grouped on the staging, form a sight that is not likely to pass from the memory.

When buds begin to push up, feed generously, but always use your stimulant weak and vary it as widely as possible. Soot water is splendid for giving depth of colour to the foliage. Clay's fertiliser, sulphate of ammonia, and liquid made from cow manure, are all invaluable in imparting intensity to the flowers.

While in full bloom, cooler conditions are desirable, and the flowers remain in good condition much longer than where subjected to stronger heat. As the autumn draws on, however, you should be prepared with the fire, so that a little heat can be circulated through the pipes at night; otherwise the moisture in the atmosphere will condense, in the form of cold dew, and every bloom will be peppered with brown dots.

As the flowers pass, give the plants plenty of air and very gradually reduce the supply of water until the last leaf has completely yellowed, then store away the pots—with the tubers in them—in a dry place where the temperature will not fall below 50° Fahr. until planting time returns.

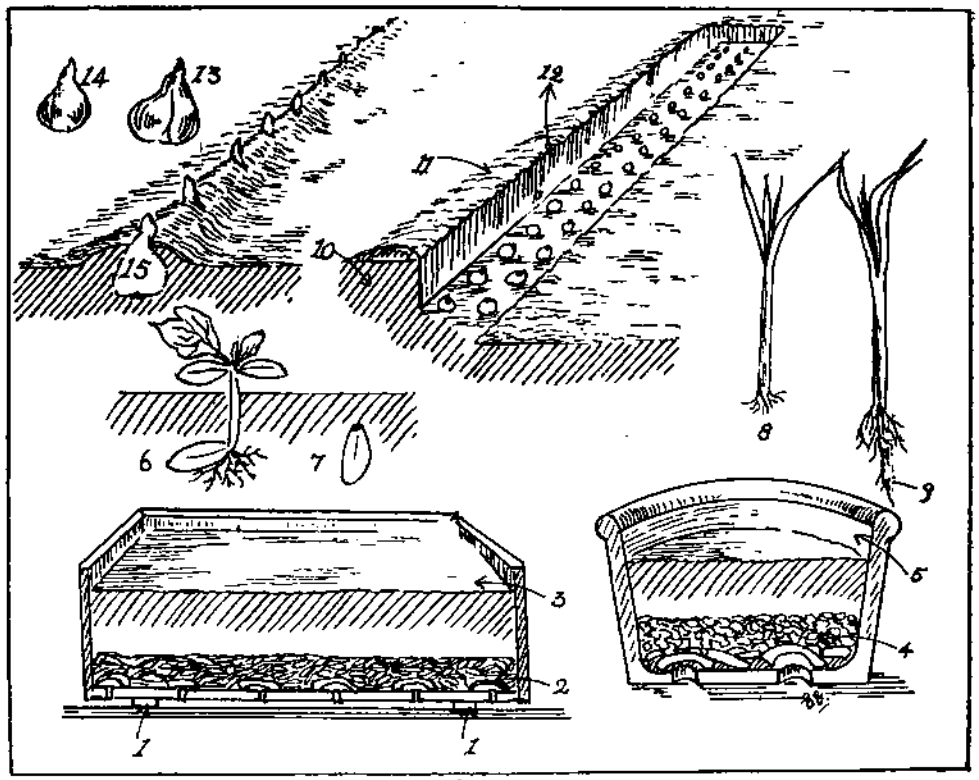
Special varieties, that it is desired to perpetuate true to name and colour, are almost invariably perpetuated by means of leaf cuttings taken from the parent plant in early summer. Choose an adult leaf and detach it from the variety you wish to increase, then nick through the mid-rib here and there with a sharp knife A pot or pan is then filled with light soil and surfaced with a quarter of an inch of sand. Water through a fine rose, and then lay the prepared leaf on the surface, pegging into contact at the nicked places with short wire pegs. Stand these pans in a brisk temperature and give sufficient moisture to enable them to root without setting up decay of the leaf.

In course of time, small swellings will appear at the nicked places, and these will ultimately develop into tubers furnished with leaves. A brisk growing temperature is essential to quick development, and the faster the young tubers can be grown on, the larger and stronger they will be before autumn. Where a sufficient temperature can be maintained, it is a good plan to keep them growing—all through the winter—as green plants. Losses during the resting season are thus avoided and large and early-flowering tubers are ensured

Whether you are dealing with seedlings, plants or leaf cuttings, the penalty of too dry an atmosphere will be thrips; the obvious remedy being to afford more moisture. Greenfly is not especially troublesome: but, when it does appear, several repeated light fumigations will clear it. Such insecticides as require spraying should be avoided, or the velvety leaves will be ruined. H. W. CANNING-WRIGHT.

TOPICAL NOTES ON VEGETABLE CULTURE

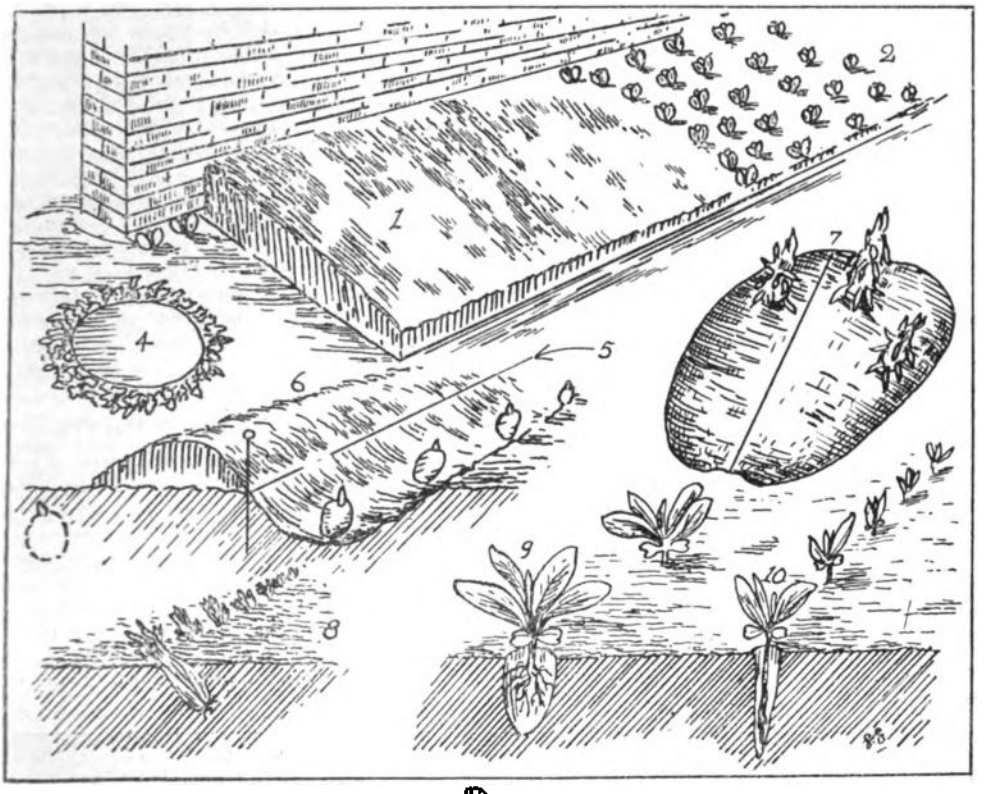
FROM day to day at this season, the sunshine perceptibly strengthens and the work of the gardener, in all branches, increases too. The wise cultivator has duly prepared the soil of the open borders, harvested a stock of compost in readiness for seedling raising under glass and also for the outside borders, where the natural loam is of a heavy nature. Not only are boxes and pans required for sowing seeds in but also for the reception of the seedlings, as most of them are improved by being transplanted once in other boxes before their final transplanting to the open border. At this season, warmth is essential to success. By the judicious selection



A

Digitized by Google

of naturally sheltered positions and the provision of temporary shelters, young plants are protected from cold winds, the soil is warmer than that in open borders and so we secure earlier germination of seeds than those sown in the former. Therefore a part of the work is done under cover and the other in the open garden. In many gardens there are enclosures in convenient places for frames and glass pits, and it is in such positions that great quantities of early vegetables can be grown independent of the start made in the open quarters of the vegetable garden itself. In these days only the most tender and refined vegetables count; there is not room for the rough and the coarse; consequently, the skill required is causing more and more interest and pleasure in the work.



B

BOXES AND PANS.—In Fig. A, Nos. 1, 1, show strips of wood nailed to the bottom of a seed or plant box. These strips not only preserve the box from premature decay, but also ensure more complete drainage, coupled with that shown at No. 2, the latter being half-rotted leaves. The bulk of the compost is shown at No. 3. This box is prepared for seeds and young plants. Nos. 4 and 5 respectively show drainage material and compost in a pan prepared mainly for seeds, such as those of tomatoes. In small pots the early cucumber plants can be raised in a compost of equal parts of loam and leaf-soil. No. 6 shows how the seed should be placed in the soil; not as shown at No. 7—if placed so the seed is, sometimes, lifted quite out of the soil during the process of germination. Many young onions and leeks will now be available for transplanting in boxes. The cultivator should be careful to preserve all the roots intact as shown at No. 9 and not mutilated as shown at No. 8. Early, round-seeded peas should be sown freely in warm borders in light soils and sparingly in those of a clayey nature. In the latter the drills should run from east to west or from north-east to south-west as shown in the sketch at No. 10, a ridge being formed on the cold side, even after the loose soil (No. 11) is placed on the seeds. No. 12 points to the north. Shallots should be freely planted during this month. In naturally moist soils early growth is encouraged by planting on tiny ridges raised with the aid of the draw hoe. Do not plant the divided sets shown at No. 13, but those similar to No. 14. No. 15 indicates the depth to plant.

THE SUNNY BORDER.—This is shown at Nos. 1, 2 and 3 respectively, in Fig. B. The raised and slightly rounded border is shown at No. 1, leaf-soil, odd loam, etc., should be mixed with the ordinary soil where the latter is cold and heavy. In such beds early potatoes, carrots, turnips, spinach and lettuces, also radishes may be grown, and the summer stocks of cauliflowers, cabbages, late leeks and, a little later, early dwarf beans, may be successfully grown. Where the soil is light or even sandy, it is the position that counts, chiefly; there is no need to have a specially raised bed, the plants being put in as shown at No. 3. While in a dry state the more forward specimens of endive should be blanched where growing by placing on them tiles, slates or boards shown at No. 4. Frequently the plants simply rot away if empty inverted pots are placed over them.

Plant potatoes in drills where the ground was manured for them last autumn. Do not tread down the soil more than can be helped; simply place the garden line, No. 5; open the drill 5ins. deep, cover the seed tubers with the loose soil, No. 6, and proceed to open another drill 2oins. away from the last one; plant the tubers 1ft. apart in the drills. Where it is desirable to cut well-sprouted tubers, do so as shown at No. 7; if the tuber bears two sprouts cut evenly; if three sprouts allow more tuber to the two, as shown, than to the single sprout; if divided into three allow, as nearly as possible, an even portion of tuber to each sprout. Rub dust charcoal on the cut sets and leave the latter in a dry shed several days prior to planting.

It may be necessary to take up the remaining celery plants in order to prepare the ground for other crops. If so, make a trench in a convenient place and "heel in" the celery close together, as shown at No. 8; firm the soil round the plants. Thousands of nice, useful plants of cauliflowers, cabbages and Brussels sprouts will need transplanting in nursery beds before their final shift to the open quarters prepared for them. In every case discard the dibber and use the hand trowel or fork, both for lifting and replanting. The future welfare of the plants depends very much on the careful handling they receive at this stage. Do the work of re-planting as shown at No. 9 and not as shown at No. 10.

GEO. GARNER.

THE EARLY-FLOWERING CHRYSANTHEMUM

DURING the past twenty-five years the early, or summer-flowering, varieties have been very extensively used for filling flower-beds and also for supplying cut flowers. If a judicious selection of varieties be made, flowers of really good quality will be available from the end of June till November.

Before the final planting work is done the wise cultivator will make his selection for both objects and treat the plants accordingly. From a miscellaneous collection some flowers will be available, but there will be gaps and the colours are sure to be mixed, the plants of certain varieties being dwarf, may be hidden by taller-growing ones. In the accompanying list the approximate height of each sort is stated, also colour.

CURRENT TREATMENT OF YOUNG PLANTS.—Cuttings may be propagated any time from January to mid-April; the ideal date, however, is the middle of February. The resultant plants grow, with ordinary care, unchecked till the flowering stage is reached. Those resulting from early propagation become hard-stemmed and stunted unless they receive suitable accommodation under glass.

I favour a rather rich compost for the cuttings to root in, also boxes in preference to pots, about one thousand cuttings being rooted in the latter annually, there being few losses. Boxes 5ins. or 6ins. deep are chosen, several holes are made in the bottom of each one, and a 1in. thick layer of rotted manure placed in the boxes. A good compost is used 2in. deep surfaced with coarse sand. The cuttings are inserted 2ins. apart, watered and covered with squares of glass. By placing the boxes so that the sun does not shine on them in the greenhouse or frame the cuttings are always exposed to the light and do not become unduly drawn up.

Roots form quickly and, in due course, the young plants should be transplanted in other boxes, retained in a cold frame for a time, then again transplanted in a nursery bed outside, or in a frame from which the lights can be removed to complete the hardening process before the final planting out about mid-May. Some gardeners grow on the old roots, but however well they may be treated, they never give such good results as young stock. Readers will, no doubt, have noticed the extra strength of the outside shoots of clumps of herbaceous plants, such, for instance, as those of phloxes. It is just the same with the old roots of border chrysanthemums. Where these old specimens must be depended upon they should be carefully lifted as soon as possible and all the strongest, outside suckers divided, the parts—small ones—being transplanted in a mixture of rotted manure, loam, leaf-soil and sand in a cold frame or in a nursery bed outside, where temporary protection can be supplied in

Digitized by Google

case of severe frosts. The inside weaker suckers should be discarded, also the stem shoots. In the meantime the cultivator should be busy digging and enriching the border soil wherein the plants are to flower. I strongly recommend the enriching of the soil. Plants grown in a poor rooting medium are generally unsatisfactory. We now possess nice, dwarf-growing sorts, and when these furnish the border with strong stems and healthy foliage the blossoms on such are, as a rule, very attractive. In the case of heavy, retentive loam, well rotted leaf-soil makes a good substitute for rotted manures, and bone meal is always an excellent stimulant. Naturally poor soils should be trenched two spits deep, otherwise the plants will partly fail in such if we have a dry summer in spite of surface mulching.

One pinching or stopping of rooted cuttings in the early part of May will be sufficient. Simply remove the tip of the shoot.

A SELECTION FOR THE BORDERS.—Champ d'Or, yellow, 18ins., flowers from June to October; Carrie, yellow, 15ins., July; Mme. Marie Masse, lilac-mauve, August, 2½ft.; White Masse; Almirante, orange-bronze, 2½ft., September; Elsenham White, 3ft., September; Ena Thorpe, shell pink, 2½ft.; Fee Parisienne, rosy mauve, 3ft.; Fire Fly, crimson-scarlet, 2½ft.; Goacher's Crimson, 2ft.; Golden Glow, 3ft.; Mary Mason, rose, 2½ft.; Normandie, pink, 2ft.; Pink Profusion, 2½ft.; Provence, rosy pink, 2ft.; Red Almirante, Sanctity, white, 2ft.; Tonkin, reddish orange, 2½ft., all flowering in September.

The following are at their best in October: Champagne, crimson, 3ft.; Cranford Pink, 3ft.; Dolores, terra-cotta, 3ft.; Elenore, rose pink, 3ft.; Etoile d'Or, yellow, 3ft.; Mignon, mauve, 3ft.; Nellie Brown, reddish orange, 3ft.; Nina Williams, crimson and gold, 2½ft.; Red Emperor, 3ft.; Satin Rose, 2½ft.; Source d'Or, reddish bronze or orange, and Lizzie Adcock, its yellow sport, both 3ft., may be planted for latest flowering and to risk frosts with.

FOR SUPPLYING CUT FLOWERS.—Almirante; Brilliant, golden bronze; Cranford Pink; Eldraco, orange amber; Elsenham White; Goodwill, apricot yellow; Miss Burchfell, rose pink; Mrs. Ward, creamy white; Nina Williams; O. J. Quintus, pink; Pink Delight; Provence, rose pink; Red Almirante; Roi des Blancs; Sanctity; Verona, terra-cotta; Source d'Or and Lizzie Adcock. The selection is made with a view to good, distinct colour effect in beds and bowls, respectively. HANTS.

CORRESPONDENCE

BERBERIS BERRIES.

THERE appeared in THE GARDEN (December 1, 1923, page 626) an interesting communication by the Rev. Joseph Jacob on berberis berries. Mr. Jacob has asked to hear of the experiences of others who have made jellies or preserves out of these berries.

We have in certain sections of the North-western States of Oregon and Washington a profusion of Berberis Aquifolium and Berberis repens. Berberis repens grows close to the ground in a straggling bunch, but in favourable situations it makes an attractive and conspicuous plant. The fruit is a handsome blue berry with a "bloom" the colour of wild grapes, contrasting well with the foliage which turns red in the autumn. Berberis Aquifolium is similar but is more upstanding and has very shiny leaves and is a beautiful plant indeed. These plants are known throughout the Pacific North-west as "Oregon Grape," and incidentally they are our state flower and are favourites with a large part of our population, as they are highly useful for landscape gardening and for interior decoration.

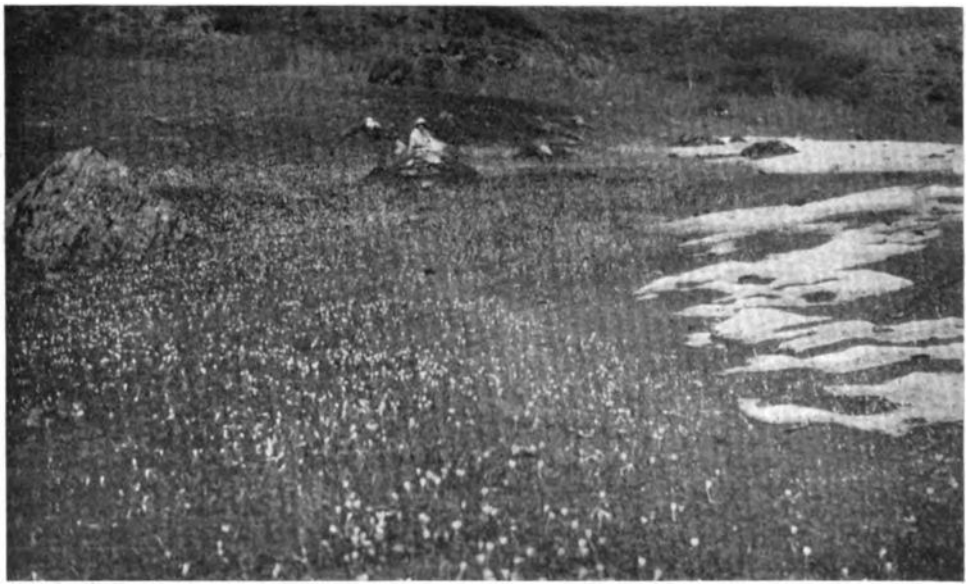
The berries of these two plants make a delicious jelly, and while it is somewhat tart, it has a fine flavour. It is doubtful whether many of our own people realise what a fine delicacy may be made from these fruits.—LEWIS A. MCARTHUR, *Portland, Oregon.*

WHITE GENTIANS.

I WAS much interested in seeing the pictures of Gentiana acaulis alba in the January 12 number of THE GARDEN, as we found it on three occasions when in Switzerland last June. We also found one plant of G. verna alba.—S. H. S., *Cornwall.*

CROCUS VERNUS IN SWITZERLAND.

I WAS very interested in the illustration of Crocus vernus in Switzerland which accompanied Mr. W. R. Dykes' most delightful article, "Some Early-flowering Bulbs," in THE GARDEN of January 5 last, especially so, as I had the pleasure of seeing these lovely little flowers growing in Switzerland last summer. Mr. Dykes says these flowers "appear in countless numbers . . . *almost* as soon as the melting snow recedes," etc.



CROCUS VERNUS IN SWITZERLAND; FLOWERING AS THE SNOW MELTS.

The enclosed photograph which I took shows that these little flowers actually come up and into bloom *before* the snow has completely gone. They are accompanied by the soldanellas, and the effect of the carpet on the dripping brown earth is wonderful. I thought that the picture might be of interest to your readers.—H. STEWART WACHER, *Canterbury.*

DISPENSARIES FOR SICK ANIMALS.

WILL you allow me to make an appeal to your readers for gifts for the gardening stall at our Shopping Fair to be held on February 25th, 26th, and 27th, at the Kensington Town Hall for the benefit of our dispensaries? Our work is growing enormously, many hundreds of sick and suffering animals being treated *daily*, and we are sadly in need of funds. We are therefore making a great effort to realise a substantial sum through our Shopping Fair and I feel sure that if your readers were to visit one of our dispensaries and see for themselves the vast crowd of animals, often in a terrible condition, which are brought to us, I should not lack a ready response to this appeal. I am also greatly in need of gifts for the produce stall, such as butter, eggs, cheese, cream, flowers, etc., and for the gardening stall I shall be very grateful to receive packets of seeds, bulbs, small rose trees, or plants of any kind. If any of your readers who are animal lovers will help me to raise funds to ease the pain of the thousands of pathetic dumb sufferers which would remain in their misery but for our dispensaries, I shall indeed be most grateful. Gifts may be sent to me at any time at 14, Clifford Street, New Bond Street, London, W.1. Perishable goods should be sent to the Kensington Town Hall on the days of the fair.—MIA DICKIN, Hon. Director, People's Dispensaries for Sick Animals of the Poor.

PROTECTING AUTUMN FRUITS.

A PEER whom I had the honour of serving was very fond of gooseberries. He was proud of his grapes when they were good enough for his visitors to admire, and they sometimes were, but for his own eating he preferred the more plebian fruit. Adjoining the garden was a large wood, in which much game was preserved, and as the keepers would not tolerate a hawk, many small birds lived and bred there, and often paid visits to the garden. Some of them were helpful, others the reverse, while others again, notably the common sparrow, were a something of both. First the sparrows thinned the fruit-buds, sometimes severely; next they carried off myriads of insects to feed their young; afterwards when the fruit was ripe, supposing any buds had been left to produce it, the blackbirds and others came to be recompensed for the good they had done earlier in the season, but they were apt to take more than their legitimate share. Well, the peer must have his gooseberries, so in order to protect both the buds and the fruit a gooseberry house was built against a north wall. It was perhaps 60yds. in length and 5yds. or 6yds. wide. Its shape was like an ordinary lean-to, and it was covered with wire netting.

Digitized by Google

We congratulated ourselves on saving the buds, but something else happened. Soon after the green leaves appeared there were hosts of caterpillars, which did much mischief before they were noticed. We managed to keep them somewhat in check by the application of insecticides, and later in the season we had a friendly visitor in the shape of a young cuckoo, which worked very diligently, and no more insecticide was wanted that season or the following one. This was the only instance I have ever known of a young cuckoo feeding itself. I have seen wagtails and hedge-sparrows working almost to death in trying to satisfy the appetite of their monster foster children, but in this case no other bird was ever seen in the enclosure. Late in September I was grieved to see my good friend lying on the ground, dead. It was starved, for there was hardly a caterpillar to be found, although I had seen a few a day or two before.

Then there were the wasps to fight against, but as I was authorised to pay for both queens and nests, these were not much trouble, even when they invaded the butchers' shops in the neighbouring town. Some thousands of queens were paid for, and though I am of opinion that some of them were not natives of that particular spot, their destruction was doing somebody good, and my employer did not grumble so long as they were kept out of my lady's boudoir and away from the gooseberries.

The variety of gooseberry which served my purpose best was Warrington (of pendulous habit), of which I had pecks of fruit hanging late in November and after the leaves had fallen. This was many years ago, and there may be other suitable varieties now. But gooseberries were not the only occupants of this cage. Morello cherries were kept long enough to be suitable for dessert, and if not sufficiently sweet for some palates, they made a beautiful dish for a large decorated dinner-table. Red currants, too, were kept till November and answered the same purpose. Then we had late plums, of which Coe's Golden Drop was the favourite, and when kept late this is a really delicious fruit. Our soil was fairly heavy; possibly, fruit would not keep so late on a light soil. Were I to build a cage for the same purpose now, I would have part of the structure movable. The upright part, which might be 3ft. in height, would be made in 6ft. or 8ft. lengths and placed on a bottom rail when in position and fastened with buttons top and bottom. These sections would be removed as soon as the buds had started sufficiently to be out of danger from the birds and replaced when the fruit was approaching the ripening stage.

A gentleman in this neighbourhood has a large patch covered with wire netting raised sufficiently high for one to walk under comfortably, and most of his small fruits, including strawberries and raspberries, are grown under it. It is a great convenience to be able to walk in and gather the fruit as required without the trouble of removing a net and the risk of leaving fruit partly unprotected when time is limited. It would be possible to grow a large quantity of gooseberries, currants and plums trained to the upright sides and in the winter and spring it might be utilised as a run for fowls, to the benefit of the poultry and the trees owing to the destruction of insects. Ducks especially would not leave many slugs to feast on the strawberries. A fixed wire cage will last many years, while nets composed of string will not. It also has some effect in sheltering from wind and spring frosts. In some districts where chemical fumes abound it is advisable to paint galvanised wire before fastening plants to it.—WM. TAYLOR, *Bath.*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—To secure really fine sprouts a long season of growth is required, and a piece of ground should be set apart for their culture. If not already done it should be given a liberal dressing of manure and dug deeply, leaving the surface as rough as possible. At the first opportunity a sowing should be made on a warm sunny border in lines 1ft. apart; but if a cold frame is available it should be utilised for raising such plants as cauliflowers and Brussels sprouts. Two or three inches of fine soil should be placed in the frame, and the seeds sown broadcast. When germination is effected, admit air, and grow them cool to ensure strong, sturdy plants. Aigburth, Exhibition and Scrymger's Giant are all reliable kinds.

Cabbage.—To supplement and follow the spring crop, a sowing of a quick-growing variety, such as Earliest or Wheeler's Imperial, may be made in boxes containing light soil. Place them in a cool greenhouse or frame, and when the seedlings are large enough to handle prick them off in a cold frame a few inches apart.

Broad Beans.—Where this vegetable is appreciated a substantial sowing should now be made. The Long-pod varieties are well known, but for quality the Windsor type should be chosen. Plant either in single or double rows, the former placed a foot apart and the latter about twice the distance.

Herbs.—New beds may be made any time now, lifting half the existing beds of perennial kinds, such as mint and tarragon, and after dividing them replant in a fresh spot which has been dug and afforded a dressing of manure. Sage, basil, marjoram and the common thyme may be raised from seed. Seed may be sown now in boxes, or in the open ground in March or April.

The Flower Garden.

Lobelia cardinalis.—There are several varieties of this fine tall plant, and perhaps Firefly is one of the best. They are usually lifted in the autumn and stored in a frame, and where this was done the clumps may now be divided into single crowns, potting all the strongest in 3in. pots. The remaining species, if needed, should be placed in boxes containing sandy soil for growing on. For a few weeks the plants should occupy a heated pit, but when well established a cold frame will suit them admirably.

Frames.—The occupants of cold frames, such as violets and violas, intended for the rock-garden will need attention from time to time, and each day due regard should be paid to ventilation. Pinch out the centres of violas and calceolarias, so as to produce nice plants with several growths, and remove all dead and decaying leaves. Stir the soil between the plants lightly with a pointed stick. When the weather is favourable the lights may be removed, especially during the day.

Dahlias from Seed.—Raising seedlings is always an interesting pursuit, and if dahlia seeds are procured from a reliable source some really fine flowers will be obtained. If the seeds are sown now useful plants will be ready for planting out in May. Both the single and pæony-flowered sorts are decorative and useful for cutting purposes. Sow the seeds in well drained pans containing light soil, and raise the seedlings in a warm house or pit. When large enough, transfer them singly to small pots and gradually harden them off till they can safely occupy a frame from which frost is excluded. The young plants should not be starved, but potted on if needed.

Dianthi, especially the rock-garden kinds, can be raised from seed. A little heat is needed at this season until the seeds have germinated; afterwards cool treatment should be the rule. August is also a good month for sowing seed.

The Hardy Fruit Garden.

Planting.—The greater part of January was too unfavourable for the planting of trees, but with better conditions such work should be finished as soon as possible. Those planted earlier in the season should be examined, to ascertain if they have become loose in the soil or if stakes have chafed the bark during rough winds.

Figs.—In some gardens it is the custom to protect the trees during bad weather, and now such material should be removed if the elements are favourable. Any pruning and nailing necessary should receive attention; the former consists chiefly of thinning the shoots rather than cutting the young growths back. Prevent overcrowding and see that the main branches are made secure to the wall. Such work may be carried out during the next few weeks.

Birds.—The bullfinches and allied species are often troublesome at this period of the year in destroying buds of cherries, damsons and plums. Later on gooseberries and currants, and also pears, are attacked. Lime and soot and spraying with quassia extract will keep them off for a time, but for the small grower or private gardener netting the small fruits will be best.

Vegetables Under Glass.

Tomatoes.—A liberal sowing is advised about this date, which will furnish plants for growing in the greenhouse, and outside, providing accommodation can be found for the latter until it is safe to plant them out in the open. Sow the seeds in pans or boxes, and place in a temperature of 60° Fahr. When the young plants have made about three leaves, pot off singly and keep them near the roof glass. T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Peas.—Pride of place should be given to this very choice vegetable and those favoured with a garden enclosed by high walls and having a south border should, if the soil has been well cultivated and manured, make a sowing of an early variety. Ameer, Earliest of All and William the First are reliable varieties, while The Pilot, although taller than some of the other early kinds, is very dependable, and takes the lead as a first early. Sow in lines 8ft. apart so that early potatoes may be grown between the lines. Those having a heavy soil should take out lines 6ins. deep and place old potting soil along the bottom to the depth of 3ins., on this sow the seeds, then cover with a layer of the same material before filling in the rows. There is the alternative of sowing in boxes or pots under glass and setting out on the border when the plants are a few inches high.

Onions.—It is advisable to sow early, yet seed may still be sown and good results obtained. Here we use ordinary cutting boxes which measure 24ins. by 14½ins., and 4ins. deep. Place in each box some decayed farmyard manure and fill to within an inch of the top with ordinary potting compost. When the surface is smoothed, sow the seed thinly and cover with fine soil. Afterwards place the boxes in one of the vineries. Ailsa Craig and Cranston's Excelsior are two splendid varieties.

Cauliflowers.—Early Snowball should be grown by all, as it is a first-rate early. It is most important that the seed should be sown thinly. Other seeds to sow now, and raise in heat, are celery, lettuce and tomato.

The Flower Garden.

Sweet Peas.—Poor indeed would be the summer and autumn supply of cut flowers without this beautiful and generous annual. To get good results the ground should have been properly and liberally manured some time ago. For one section of our sweet pea hedge we sow the seeds now in V-shaped boxes each 6ft. long, 4in. boards are used to construct the boxes, and smaller pieces of wood are fixed at the ends, and so placed that the boxes stand quite steady when in use. The ends can easily be detached, and the plants slipped into the prepared ground without much disturbance when planting time comes. The boxes are filled with ordinary potting soil and pressed level; holes are made between 2ins. and 3ins. apart and about 1in. deep, in two lines, and a seed dropped into each hole and covered over. The boxes are then placed in one of the greenhouses and watered. Varieties are numerous, but any of the well known kinds enumerated in the catalogues of high-class seedsmen will give satisfaction.

Geraniums.—If these plants are used for summer bedding the young rooted cuttings should be placed separately in 4in. pots—or massed if this old custom is still practised—and the plants placed in a brisk heat for a few weeks. Antirrhinums and East Lothian Stocks may still be sown in pots

Digitized by Google

or pans filled with fine sandy soil and raised under glass.

Fruit Under Glass.

Vineries.—The work of thinning and pinching the young growths in the early house should be done at intervals, and a night temperature of 55° to 60° maintained. In the late house the cleaning of the woodwork and vine rods should be done without delay. Gishurst Compound is a useful and safe insecticide, and the proportions to use can be ascertained from each box.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

GREENHOUSE AND CONSERVATORY.

Sweet Peas that were sown during autumn and are now in 48-sized pots, should be ready for a shift into the pots in which they are to flower. These pots should be eight to ten inches in size. The potting compost should consist of a good loam, some dry well decayed cow manure, a six-inch potful of fine bone meal to every bushel of compost and enough sand or old mortar rubble to keep the whole open and porous. The plants should be potted firmly and stood in a cool, airy greenhouse. Water should be very carefully given until the roots get a good hold of the fresh compost. The plants should be grown under perfectly cool conditions at all times, and in their younger stages should be supported with some slender sprays of hazel and as they increase in length kept neatly tied to slender canes.

Ardisia crenata, with its dark green foliage and bright red fruits is a very useful plant for the conservatory, as the fruits remain in good condition for at least six months. This plant takes three years to reach its fruiting stage so it is therefore important to keep up a succession by raising a batch of plants each year. This plant may be propagated by means of cuttings at this time, but they are really best raised from seed, which should be sown now. The seed pots should be plunged in a bed with bottom heat at command, as the seeds usually take some time to germinate.

Cyclamens raised from seed sown last August should now be ready for potting. If they have been grown in pans or boxes they should be placed in small sixty-pots; if, on the other hand, they have been grown during the winter in thumb pots they will stand a shift into large sixty-pots. The compost should consist of a good loam with a little leaf soil added, while instead of sand it is an advantage to use some old mortar rubble. Cyclamens enjoy a moist atmosphere at all times, and in their younger stages may be given a fairly high temperature—55° to 60° being suitable. As the season advances they should gradually be given cooler conditions and during the summer months are best grown in cold frames, from which the lights can be pulled off at night, so that they get the benefit of the dews.

Begonia semperflorens and its many fine varieties are in the south largely used for summer bedding, while in the colder parts of the country they are equally useful for the conservatory and greenhouse. They are easily raised from seed sown at this time. The seed pots should be stood in a warm house, and covered with pieces of glass until germination takes place; when large enough to handle the seedlings should be pricked off into pans or shallow boxes containing light rich soil. When large enough the plants may be placed in small pots, shifting them on as they require it. Five-inch pots being generally large enough for the plants to flower in. If desired they may be grown on in boxes, and afterwards planted out in a bed of rich soil in cold frames. By this method fine large plants are obtained which can be lifted and placed directly into their flowering pots.

Royal Botanic Gardens, Kew. J. COUTTS.

OBITUARY

MR. A. M. BURNIE.

IT is with much regret that we have learned of the death of Mr. Archibald M'Indoe Burnie, one of the directors of Messrs. Dobbie and Co., nurserymen and seedsmen, of Edinburgh. Mr. Burnie had been in ill-health for some little time, but was going about until shortly before his death, which took place at a nursing home in Edinburgh. Originally, Mr. Burnie was connected with the profession of banking in Rothesay, of which town he was a native, and where he was interested in public affairs and was a member of the Town Council and Burgh Treasurer. About thirty years ago he entered the firm of Messrs. Dobbie and Co., devoting himself with much success to taking charge of the financial department. Mr. Burnie was very highly esteemed and was an active member of a number of benevolent and social movements in Portobello and district. He was in his sixty-third year, and resided with his sister at 18, Hillhead Road.

Answers to Correspondents

ROCK GARDEN.

GERMINATION OF ANEMONE SEEDS (C., Surrey).—Seeds of Anemones alpina, sulphurea, Pulsatilla, narcissifolia and sylvestris, will germinate if sown in the spring, but, naturally, they will be longer in coming up. Many will probably lay dormant till the following spring. Keep the seed pots in a cold shady frame, and do not allow the surface to become covered with liverwort or moss. A layer of sharp silver sand will prevent this to a great extent. Seeds sown in the autumn and exposed to the frost during the winter usually germinate freely in the spring.

TREES AND SHRUBS.

SHRUBS FOR HEDGES (C. E. A.).—About mid-April is a good time to prune a hedge of Cupressus macrocarpa. It depends on the condition of the trees and the ultimate height of the hedge how soon it is desirable to commence pruning. If a height of 10ft. is proposed no cutting need be done this spring, but stop the leading shoots when 5ft. or 6ft. high. The Laurustinus, Viburnum Tinus, is a good shrub for an evergreen hedge in the south and west. The escallonias are popular hedge plants, E. macrantha being perhaps the best.

MALE AND FEMALE SHRUBS (W. J. T.).—It is only possible to determine which are male and which are female aucubas, skimmias and sea buckthorns when the plants are in flower or fruit. Some slight knowledge of botany is necessary to aid in distinguishing the parts of a flower. The stamens with pollen grains represent the male, and the pistil the female. In the great majority of flowers these two organs occur in the same flower and fertilisation is easy. These are termed bisexual flowers. In the case of the aucuba, sea buckthorn and Skimmia japonica the flowers are unisexual and borne on different plants. Only the female plants produce fruits but to pollinate the flowers about one plant in every six grown should be a male. In Skimmia Fortunei male and female organs are borne on the same plant.

MISCELLANEOUS.

TRANSPLANTING COMMON POLYPODY (F. G.).—This operation may be carried out in the early spring, just before the plants start growing. Choose a shady position and use plenty of leaf-mould and sand in the soil.

NAME OF FRUIT.—H. B. L.—Apple Minchall Crab.

NAMES OF PLANTS.—A. C., N. B.—1, Calanthe vestita rubro-oculata; 2, C. Bella; 3, C. Byran; 4, C. vestita rosea; 5, C. v. luteo-oculata.

DWARF-GROWING VERONICAS for the ROCK GARDEN

"Speedwell" is the common name for members of this genus, which consists of some 160 species of hardy herbs, shrubs and small trees, widely dispersed over the temperate and cold regions of the North and South Hemisphere. For the rock garden many of the low-growing kinds are very valuable, growing into large carpet-like patches that are covered in season with masses of flowers in various shades of colour. Pure white, blue of almost gentian hue, pretty shades of rose and rich purple are all represented in various species. Besides those species of herbaceous habit are some fine dwarf shrubby kinds, natives of New Zealand, which are beautiful in form, some resembling small conifers, while others take on the appearance of the club mosses. They are valuable evergreen plants, very useful for furnishing the rock garden during the winter. All are easy to grow in any good, well drained loamy soil, the herbaceous kinds being propagated by division in the autumn or early spring, while the shrubby species are easily increased by means of cuttings in the summer. Although some sixteen species are found wild in this country, only one, V. spicata, is grown much in gardens. Another well known plant is V. Chamædrys, one of our prettiest wild flowers. Taking the herbaceous kinds first, the following are some of the best and most suitable for growing in the rock garden:

V. Allionii.—This charming dwarf rock plant from Spain only grows 6ins. high and produces long spikes of lovely deep blue flowers from May to July.

V. alpina is a rare native plant that grows on some of the higher Scotch mountains, as well as being found over the whole of the North Temperate regions. It grows about four inches high, and bears blue violet flowers in short spikes during the months of June and July.

V. austriaca (syn. V. multifida).—This plant is almost tall enough for the herbaceous border, and may be welcomed in the rock garden for its neat habit. It makes bushy plants about 1ft. high and bears large flowers in long spikes of a good blue. These are produced in succession from June till early autumn, the var. pinnatifida, with leaves more deeply divided, has flowers of a deeper shade of blue. This species is a native of Europe.

V. bombycina is a beautiful species from Syria, with white woolly leaves and pretty blue flowers. It requires a sunny position in gritty soil, with protection for its foliage in winter from wet.

V. cæspitosa.—This is a rare plant, found in Palestine on the higher Lebanon, above the cedars. It also has white woolly stems and leaves with large pink flowers in small spikes. It requires the same treatment as the above species and grows about six inches high, flowering in June and July.

V. canescens is similar in habit to the well known Arenaria balearica, and is a miniature species from New Zealand. It is perfectly hardy in sandy soil, forming dense carpets of slightly hoary minute leaves on creeping, rooting stems. The pale lilac flowers are comparatively large and present the appearance of having been strewn thickly on a carpet.

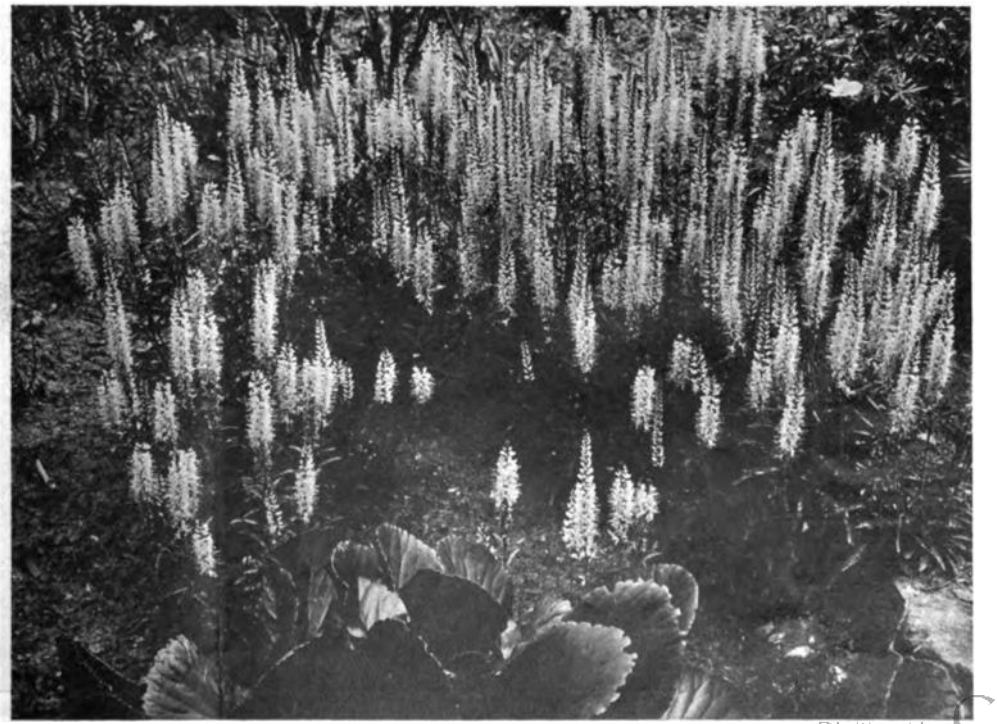
V. cinerea.—This is another hoary leaved species from Asia Minor with pale blue flowers that is somewhat tender in our damp winters. It requires a well drained sunny position.

V. filifolia has most elegant, finely divided foliage on stems about 6ins. high and should be grown in every garden. In May and June it produces numerous pale blue flowers in short racemes. It comes from Russia and is one of the most easily grown kinds, soon forming large tufts that flower profusely.

V. gentianoides.—Although more of a border plant, this is useful for the larger rock garden. Generally about 1ft. high, with broad leaves and long racemes of blue or white flowers, it is variable in habit and there are several varieties grown in gardens. It comes from the Caucasus and flowers in June and July.

V. incana is a very effective dwarf species from South and Eastern Europe, with silvery white foliage and racemes of deep blue flowers. The latter are produced on stems some 8ins. high during the months of June to August. Like many others it is very variable in habit, there being forms with larger leaves and flower stems 18ins. in height.

V. orientalis (syn. V. taurica).—This is a



AN IDEAL PLANT FOR THE ROCK GARDEN, VERONICA SPICATA ALBA.

Digitized by Google

A GOOD FORM OF VERONICA INCANA.

somewhat lax growing plant, with diffuse or decumbent stems, linear entire or toothed leaves, and bears flesh coloured flowers in loose racemes during July. It comes from Asia Minor and grows about 9ins. high. The variety tenuifolia has narrow leaves and deep blue flowers.

V. PECTINATA is a prostrate species with trailing stems, the entire plant being covered with grey woolly hairs. It bears short racemes of blue flowers in May. A native of Greece, there is also a rose-coloured form that is prettier than the type.

V. PEDUNCULARIS.—Hailing from the Caucasus and Asia Minor, this plant grows nearly one foot high. It has pretty foliage and pure white flowers, the latter being produced from April to June. For many years it was grown in gardens under the name of Veronica "E. C. BUXTON."

V. PROSTRATA (syns. V. Teucrium var. dubia, and V. rup stris).—This is one of the most attractive species grown in the rock garden. It makes an evergreen carpet, and from May onwards produces a wealth of gentian-flowers in long racemes. The whole plant is only a few inches high, and is a valuable subject for massing, or for growing on ledges where the prostrate stems can hang down and form a curtain. There is also a variety with pure white flowers. A native of Europe, this plant has been for a long time classed as a variety of the variable V. Teucrium, an erect plant some 18ins. to 2ft. high. It is however, quite distinct, and V. prostrata is a more appropriate name.

V. SATUREIOIDES is a dwarf plant from Dalmatia with creeping stems and rich blue flowers in May and June. It is somewhat like the above but does not flower so freely.

V. SAXATILIS, "Rock Speedwell."—This is a beautiful little rock plant that is found on some of the higher mountains of Scotland. It is of tufted or trailing habit with woody stems 4ins. to 6ins. high and rich blue flowers ½in. across, with a crimson eye. It flowers from June to September. A plant frequently met with in gardens under the name of V. Guthriana is a form of this of more erect habit, and self blue flowers. There is also a pure white variety. V. saxatilis is found on most of the mountain ranges of Europe and is worth a place in every rock garden.

V. SPICATA is another native plant of variable habit, the smaller forms of which are ideal rock plants; some are only 6ins. high and bear dense spikes of rich blue flowers from August onwards. There are also forms with white and rose-coloured flowers.

V. TELEPHIFOLIA.—This is a remarkable prostrate plant from the Caucasus, with glaucous foliage and pale rose or blue flowers in May. It is an excellent groundwork for early-flowering bulbs.

A selection of the woody New Zealand species should include:—

V. AMPLEXICAULIS.—This is a decumbent shrub, with clasping, glaucous leaves. It grows about 1ft. high and bears short dense spikes of white flowers. Others closely allied to this, and similar in habit are VV. carnosula and decumbens.

V. ASTONI is a dwarf little plant only 3ins. high forming selaginella-like tufts and bearing pale lilac flowers.

V. BIDWILLII is an evergreen prostrate species forming a mat of interlaced stems. From these are produced long thread-like flower stems bearing short racemes of starry white of pale lilac flowers in June. It is a rare plant in gardens, the taller-growing V. Lyallii often doing duty for it.

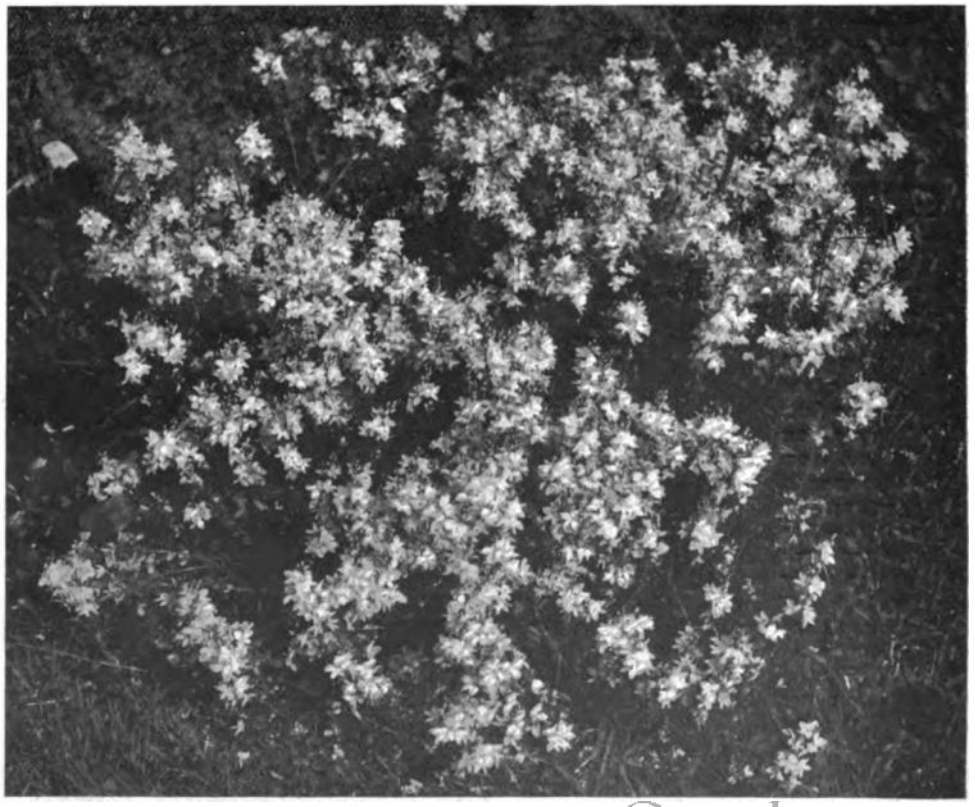
V. CATARRACTÆ is a small shrub 1ft. or more high, closely allied to V. Lyallii, differing in its larger leaves and dense racemes of white flowers. It is variable in habit like most of the New Zealand Veronicas, there being forms with smaller leaves and pink flowers which makes it difficult to distinguish from V. Lyallii.

V. CHATHAMICA is a small, prostrate, rambling shrub well adapted for covering stony banks in the rock garden, where it will thrive in partial shade. It has wiry pubescent leaves and large, dark purple flowers in short racemes.

V. COLENSOI.—This is a small shrub about 18ins. high, some forms having glaucous rounded leaves. It makes a handsome plant for the rock garden and is very free-flowering, its pinkish white flowers being produced in dense racemes during the summer months.

V. CUPRESSOIDES.—The plant usually seen in gardens under this name is a garden hybrid, the correct name of which is V. azurea. V. cupressoides makes a bush 2ft. or more high, of elegant habit, with much branched stems like those of some of the cupressus. The pale lilac flowers are borne in racemes during the summer.

V. LYALLII is a very variable plant, generally about 6ins. high, with slender stems, ovate, serrate



THE WHITE VARIETY OF VERONICA PROSTRATA.

Digitized by Google

leaves, and white flowers with pink veins, darker near the throat. It lasts in flower for a long time during the summer months. Although it sometimes gets killed down to the ground in severe winter it breaks up freely from the rootstock.

V. LYCOPODIOIDES is a lycopodium like plant of nearly prostrate habit, with stems covered with small, densely imbricated leaves. It only grows about 6ins. high and bears white flowers in small, dense heads.

V. PROPINQUA (syn. V. salicornoides).—This charming little plant is of prostrate habit and only attains a few inches high. The leaves are small and closely set on the stems, while the whole plant has a golden appearance. In summer the small violet flowers are produced in short racemes.

V. PIMELEOIDES is a pimelea-like shrub of semi-erect habit up to 1ft. high with glaucous leaves and deep purple flowers in summer. It is a very ornamental plant for the rock garden.

V. PINGUIFOLIA has glaucous foliage like the above but more rounded leaves. The flowers are white and produced in June. Both are excellent plants for the rock garden with their evergreen foliage, which is very attractive during the winter. W. I.

SPRING TREATMENT OF TREES AND SHRUBS

WE give special attention to the pruning and mulching of fruit trees and bushes. It is equally necessary, if the best results are to be obtained, to prune and mulch ornamental shrubs. Although they interlink, it will be easier to discuss the subject of pruning deciduous shrubs and evergreen shrubs separately.

The pruning and thinning of the shoots of deciduous shrubs is intimately concerned with the flowering season of the genus or species. There are two main reasons for the work (1) the growth and maintenance of shapely bushes and (2) the development of flowering wood. The growth of the flowering wood naturally allows of the division of flowering shrubs into two broad groups, viz., (1) those which produce flowers on the previous year's wood and (2) those that blossom on the current season's growths. The first group, for the most part, flower in spring and early summer. Hence it is obvious that anything beyond the thinning of crowded shoots should not be attempted in winter or spring. The best time for pruning this section is after flowering: thus allowing new growths to develop and mature during the summer and autumn. Examples in this section include forsythias and Jasminum nudiflorum.

In order to encourage strong new shoots on the shrubs which blossom during summer and autumn, there are many it is possible to improve by liberal pruning during February or March. Examples include Hydrangea paniculata, Spiræa japonica varieties and Buddleia variabilis.

The thinning and shortening of the growths to obtain shapely bushes and sturdy well ripened wood is on a par in importance with that of pruning to obtain flowering wood. The best time for thinning is after flowering, but the actual time for the work need not of necessity be so closely practised as is done for flowering wood.

EVERGREENS.

A number of evergreen shrubs are highly valued as flowering bushes, but on the whole, rhododendrons excepted, their greatest asset is as ornamental evergreens. The best time to prune evergreens hard is during April or early May, when new growth is beginning. In actual practice many shrubs require little, if any, pruning, but in course of time, with succeeding years of growth, the bushes either become too large for their positions or grow leggy and not particularly attractive. Cases in point may be quoted of rhododendrons, Olearia Haastii and Veronica Traversii. These break away freely from the older wood when cut hard back, but it means sacrificing a season's flowers, though this loss is compensated for by vigorous new growths. The normal clipping of box, holly and yew hedges is done in July or August, but any severe cutting back into the older wood should be attended to in late April or May, according to the season. Through many years of growth or because of neglect during the war old hedges may have got out of hand. A good proceedure is to cut the growths on one side and the top hard back with the secateurs one year and a year later cut back the remaining side.

One of the worst hedges to get out of control or to need drastic treatment is the common cherry laurel. It is fortunate that the cherry laurel is also one of the quickest to recover from a hard pruning. Stems as thick as one's leg cut down in May to within 2ft. or 3ft. of the ground speedily send up vigorous new shoots. These may with advantage be topped once or twice.

In company with hard pruning cultivation of the surface soil round the bushes or along the hedges is important. Follow this up with a liberal mulching. Watering during dry weather and spraying morning and evening on sunny days will be beneficial. All cuts larger than the top of one's little finger should be dressed with tar to prevent decay and the attacks of fungoid diseases.

BUDDLEIA VARIABILIS IS EMPHATICALLY A SHRUB FOR HARD PRUNING.

Digitized by Google

The very extensive collection of shrubs at Aldenham may be quoted as an ideal example of careful and constant shaping and pruning.

The list given at the end of this article of about fifty examples of pruning and mulching may serve as a guide to new lovers of flowering and ornamental shrubs.

MULCHING.

There are two main reasons for mulching trees and shrubs (1) the supply of additional nutriment to the soil and (2) conserving moisture in the ground for the roots. The most generally used material for mulching is decayed animal manure and straw. It is usually described as farmyard manure, which may mean a general mixture of dung from horses, cows and pigs. Stable manure infers horse dung, while perhaps the most valuable of all for general use is cow manure. We are not always in a position to practise the idea, but for preference use cow manure on light soils and horse manure mixed with plenty of straw on heavy ground.

The heating properties of horse manure are made use of in the preparation of hot-beds. While this property is valuable for some purposes it is harmful to young fibrous roots, hence, when mulching, only well decayed manure in which the heat is practically spent should be used. This is not the place to go into details with regard to the difference in the chemical properties of horse and cow manure, the subject being treated from a practical rather than a theoretical standpoint. Used in the garden the cooling property of cow manure in contrast to horse manure is a valued asset.

The introduction of motor transport has enormously reduced the supply of stable manure for horticulture, and in the neighbourhood of large towns sanitary bye-laws have caused the removal of most of the cowsheds to country districts, complicating matters still more. In addition to leaves, much more use could be made of decaying vegetable refuse as a mulch. In Cornwall and elsewhere bracken and twigs (prunings, etc.) are largely mixed with leaves as a mulch for rhododendrons. The twigs have an additional use in anchoring the leaves until well decayed. The stems of Michaelmas daisies, heleniums, helianthemums—in fact, all kinds of herbaceous plants—supply excellent material for mulching, in some cases perhaps reduced in length by chopping to render more usable. The question of animal manure for rhododendrons is a debatable point. We sometimes use one part of very well decayed manure to two or three parts of leaves, when the latter are light and flaky, to give body and some anchorage to the mulch. Decayed cow manure is preferable to horse manure. In some ways it is probably a waste of valuable manure, for rhododendrons are not gross feeders, decaying vegetable manure supplying all the nutriment necessary. Grass from lawns and other mowings provides useful material for mulching when applied with care. It is preferable to mix with leaves or twigs and mulch rather thin, otherwise the grass may become a close, wet, putrid mass and do more harm than good to the roots.

The question of when to apply the mulch must be largely a matter of convenience. With dahlias and sweet peas, for instance, the summer is usually well advanced and the ground warm before it is applied. It is perhaps the best time to mulch spring-flowering shrubs when the pruning is done after flowering. Against this must be set the smell and some mess in applying the manure. This would pass unnoticed in February or March, but may be objected to in public and some private gardens during May and June when the pleasure-grounds are at their best.

NAME.	*PRUNING.*	*MULCHING.*
Aucuba japonica	Shorten long growths to shape bushes.	Manure seldom required.
Bamboos	Cut out older canes to base if crowded or shabby looking	Good dressing of cow manure in May.
Berberis Aquifolium	Cut over bushes and undergrowth during April to maintain trim and well kept appearance	Mulching only required on very poor soils.
Berberis deciduous species	Cut out oldest wood about February to thin and shape bushes	Fruiting species improved by liberal mulching of farmyard manure in spring.
Buddleia globosa	Only requires pruning in April when bushes grow too large	Old hot-bed or mushroom manure in April.
Buddleia variabilis varieties	Cut fairly hard in March, the best flower spikes are borne on vigorous new shoots	Liberal dressing of farmyard manure in April or May.
Buxus sempervirens	Reduce size of box hedges and bushes, when required, in early May	Old hedges improved by dressing of cow manure in May.
Caryopteris Mastacanthus	Shorten wood of previous year in March	Old hot-bed or mushroom manure in April or May.
Ceanothus, spring-flowering	Shorten growths on walls and fences after flowering	Ditto. ditto.
Ceanothus, summer and autumn flowering.	Shorten growths of previous year in March	Decayed farmyard manure in May or June.
Choisya ternata	When required cut back branches to reduce size and shape bushes in April	Cow manure April.
Clematis, spring and early summer flowering	After flowering end May, June	Farmyard manure in spring.
Clematis, summer and autumn flowering	Take out weak growths and thin ends of most, prune Jackmani varieties rather harder	Ditto. ditto.
Colutea arborescens	Shorten previous year's wood in March	Farmyard manure in May if soil is poor.
Cydonia japonica varieties	Trim and shorten branches after flowering if required	Cow manure May-June.
Cytisus nigricans	Shorten growths of previous year in March	Manure seldom required.
Deutzias	Take out old growths after flowering	Farmyard manure in June.
Diervillas (Weigelas)	Thin out by removing oldest wood after flowering	Farmyard manure April.
Escallonias	When getting too big, reduce size of bushes, hedges and wall plants in April.	Cow or farmyard manure in April.
Euonymus, evergreen	Shape bushes by drawing out long growths end of April or May	A little hot-bed manure on poor soils.
Forsythias	Shorten old flowering shoots in April	Farmyard manure in April.
Fuchsias	Cut back to firm living wood or down to ground as required in March	Old hot-bed or mushroom manure in May.
Hydrangeas arborescens and paniculata	Hard pruning in March, thin crowded shoots at the end of April	Liberal supply farmyard manure in June.
Hydrangea Hortensia	Cut off old flower-heads and thin after flowering	Hot-bed or mushroom bed manure in April.
Hypericums	Liberal pruning in February or March	Well decayed farmyard manure in June.
Ilex Aquifolium varieties	Hard pruning end of April or May, clip hedges in July or August	Moderate dressing of farmyard manure.
Jasminum nudiflorum	Liberal pruning end March after flowering	Apply well rotted stable manure in April.
Jasminum officinale	Thin stems February or March	Ditto. ditto.
Kerria japonica	Cut out old flowering stems to ground end May or early June	Farmyard manure in June.
Laurus nobilis	Trim bushes of bay with secateurs in May	Old decayed cow manure in May.
Ligustrums	The golden and green-leaved privets may be cut back hard into the old wood during May.	Privets seldom require manure unless the ground is very poor or the bushes long standing.
Lupinus arboreus	Liberal pruning of the tree lupins should be done in March	Hot-bed or old mushroom manure in May or June.
Myrtus communis	The common myrtle should be pruned on walls and the bushes dealt with at the end April if required	Cow manure or ditto.
Olearia Haastii	The daisy bush should only be pruned when too large, then cut hard into old stems	Ditto. ditto.

NAME.	PRUNING.	MULCHING.
Philadelphus species and named sorts ..	Thin out oldest wood end June to July, after flowering ..	Liberal mulching of farmyard manure in July.
Philadelphus Lemoinei erectus	Cut out old flowering stems down to ground each year after flowering	Ditto. ditto.
Phillyreas	When outgrown positions cut hard back to main stems in early May	Old farmyard manure only when hard pruned.
Prunus triloba flore pleno	Cut the year old flowering shoots hard back end of April ..	Decayed stable manure in May.
Rhododendrons, evergreen	Hard pruning if absolutely necessary should be done end of April Shortening of a few long shoots after flowering	Mulch with decaying leaves and other vegetable manures from May onwards.
Azaleas	Remove old crowded flower heads or stems after flowering ..	June ditto.
Ribes	Thin growths of flowering currants in April	Farmyard manure April or May.
Rosa species	Remove old wood of wild rose in February or March	Farmyard manure March or April.
Sambucus nigra foliis aureis	Cut back the stems of the golden elder in March	A little manure may be given in alternate years if the soil is poor. April.
Salix vitellina..	Prune back the red and yellow stemmed willows in March ..	Manure seldom necessary.
Spartium junceum	The Spanish broom gets very leggy unless pruned each year in March, especially young plants	No manure required.
Spiræas, summer and autumn flowering ..	Prune freely in March	Farmyard manure April or May.
Spiræas, spring-flowering	Thin in May and early June after flowering	Liberal dressing of farmyard manure in June.
Tamarix pentandra (syn. T. hispida æstivalis)	Prune the autumn-flowering tamarisk hard back in March ..	Seldom requires manure if soil good.
Taxus baccata vars	Any hard pruning required should be done in May	Cow manure in spring if thought desirable.
Tecoma radicans	Cut young wood hard back in March	Stable manure, June.
Veronica Traversii	Only prune when bushes overgrown, then cut stems well back into old wood in early May	Cow manure, June.
Viburnum Tinus (Laurustinus)	Tall unwieldy hedges or bushes may be hard pruned back to old stems in May	Cow manure or hot-bed. Manure in May.
Vitex Agnus-castus	Shorten previous autumn flower shoots in March	Ditto. ditto.
Vitis species (Vines)	Prune little or much as desired in December or Jaunary ..	Farmyard manure, April.
Wistarias	Shorten new trailing shoots in summer, spur back wall trees in February	Ditto. ditto.

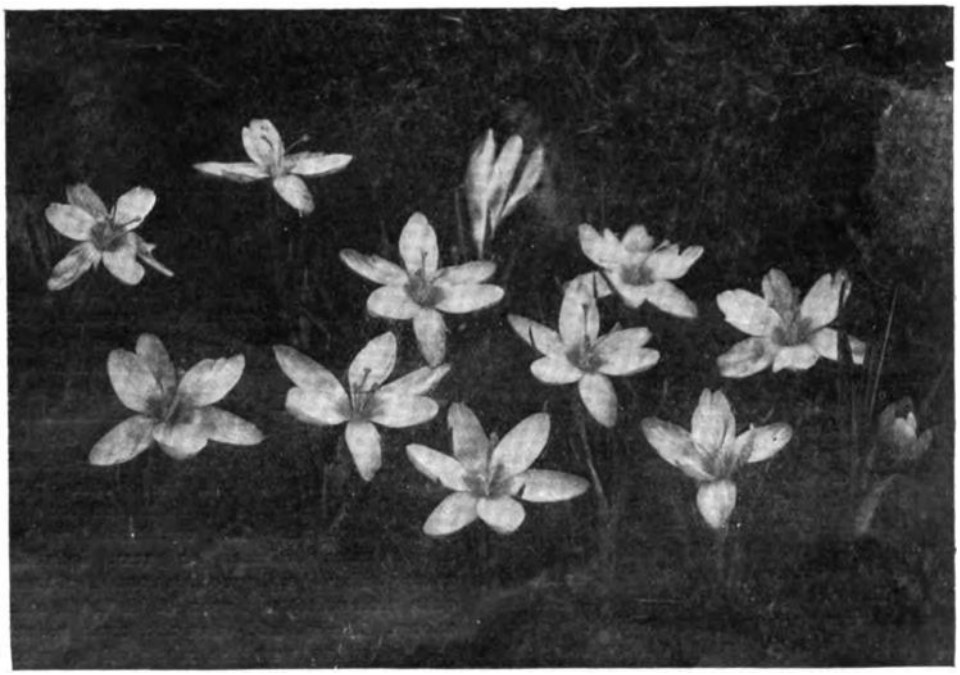
A. O.

EARLY HARDY FLOWERS IN A SUBURBAN GARDEN

THE last Sunday in January was bright and sunny even in a London suburb, and I expected that the heavy rains of the preceding week would have brought the buds of a few early bulbs to the flowering point. For some reason or other my early spring flowers are very late this year, and I wonder whether other gardeners are having the same experience. At first I was inclined to think that their lateness might be due to the fact that all my bulbs had to be lifted last summer and replanted in the autumn. This lifting tends, I think, to a more thorough ripening of the bulbs, which causes them to remain dormant until late in the autumn, and the new growths are therefore later in making their appearance above the ground. But it happens that I have some tulips and other bulbs which were dug up last summer in Asia Minor and Palestine, and all of them are very precocious in their growth. Is this due to the fact that the leaf growth was not mature when the bulbs were dug up, or what other reason can there be for their early appearance here?

Iris unguicularis is behaving well this year. I have to grow it in heavy clay in a most unlikely spot, but before planting my clumps I dug in a sackful of old mortar rubble, and at present I am picking some half-dozen buds every day. Of my neighbours, none seems to know it or ever to have heard of it, and they will hardly believe their eyes when I show them where I pick the buds. Then they begin to wonder why they do not all grow this wonderful plant, and I cannot help wondering too.

Iris Rosenbachiana has not enjoyed the change from the Surrey hills to Merton, and I am grieved to find that my plants are dwindling away. Usually I have had many in flower by the middle of January, but now there are only a few of the fat green points just breaking through the soil. I am afraid it means that most of the bulbs of the true early-flowering I. Rosenbachiana are dead and that there only remain a few of the closely related I. baldschuanica, which is distinguished by its white pollen and its later flowering habit.



CROCUS SIEBERI WITH BLUISH LAVENDER FLOWERS.

No snowdrops are out yet, though the buds are showing, not even the big, early-flowering hybrid which Canon Ellacombe used to grow at the foot of the famous wall at Bitton, where it was a wonderful sight in January. Somehow or other, it had got the name of Galanthus Imperati, though it is certainly not the true plant. The real species comes from the hills some ten miles inland from Naples and is a large-flowered late form of G. nivalis. I have, fortunately, been able to get a number of bulbs collected and, though there is considerable variation among them in the size and shape of the flowers, none of them is like the Bitton plant.

Another plant from the neighbourhood of Naples is one of the best, or even the best, of winter-flowering crocuses, namely, Crocus Imperati. The first flowers seldom fail to appear early in January, and the display goes on all through February, for each good corm sends up several flowers in succession. The buds of the typical form are

Digitized by Google

of a pale light buff on the backs of the outer petals, usually with three feathery, brown madder veins running up them. The surprise comes when, as the sun grows stronger towards midday, these pale petals separate and show that the inner petals are a warm lilac, often of a distinctly pinkish shade. There is also a white form, in which the outer petals are tinged with cream.

Crocus Sieberi with its bluish lavender flowers is another sturdy species that is worth a place in every garden. Many of these were in full flower and formed a pleasing contrast to the rarer C. Korolkowi, the yellow flowers of which are veined and speckled with brown on the backs of the outer petals. Both these crocuses increase readily from seeds, and yet good patches of them are seldom seen.

C. Tauri from Cilicia is an amazing colour. As it grows in the garden it is easily the bluest of all crocuses, and when it is closely examined the colour is found to be almost ultramarine, which shades away into orange at the base of the petals. C. Tauri is, unfortunately, still very rare in cultivation, but the corms increase steadily, even if not very rapidly, by offsets. Equally rare is C. Leichtlini, which is really lovely in its delicate colouring. The three outer petals are white, shaded on the back with a light Prussian blue, which changes to green at the base. The inner petals are of the palest and most delicate cobalt blue, and the open flower shows the small orange stigma surrounded by green anthers with golden pollen.

C. chrysanthus was just beginning to flower. A few buds of the soft, butter yellow variety, E. A. Bowles, had already appeared, and one fine seedling with heavy crimson madder shading on its outer petals was already wide open. It had the typical rounded goblet shape and the strong scent of honey.

The last flowers of C. marathonisius from Mount Taygetus in Southern Greece were not yet faded, though the first appeared as long ago as the last week in October; and near them were the golden C. mœsiacus and the even deeper, strangely named C. candidus, which is distinguished by its very broad leaves.

Near them were the first flowers of Iris histrioides. The colour is a bright blue and the only fault is that there is no sign of the leaves when the flowers appear. For this very reason it is one of the easiest of the Reticulata group to manage, for its foliage has more chance of escaping damage by bad weather and of building up sound bulbs for the following year. The flowers of several specimens of the so-called I. sophenensis were close alongside and proved by their close similarity that it is merely a small form of histrioides. It shares its good constitution, for it has flourished with me now for some ten or fifteen years. When a bulb flowers it seems to die, but to leave behind it a numerous progeny of very small bulbs, which, however, grow on to flowering size in two or three years.

The only other iris was a very beautiful and richly coloured hybrid of I. Bakeriana and I. reticulata. The blade of the fall is of the most velvety, deep purplish black with a small central white patch and a yellow median ridge. This hybrid seems to be increasing, but it is one of the few survivors of the numerous varieties which resulted from the cross and which, unfortunately, were nearly all of them killed by unavoidable neglect during the war. The flowers are earlier and more brilliant than those of I. reticulata, and the leaves show their hybrid origin in the fact that they are cylindrical with six ribs instead of the eight of I. Bakeriana and the four of I. reticulata.

W. R. DYKES.

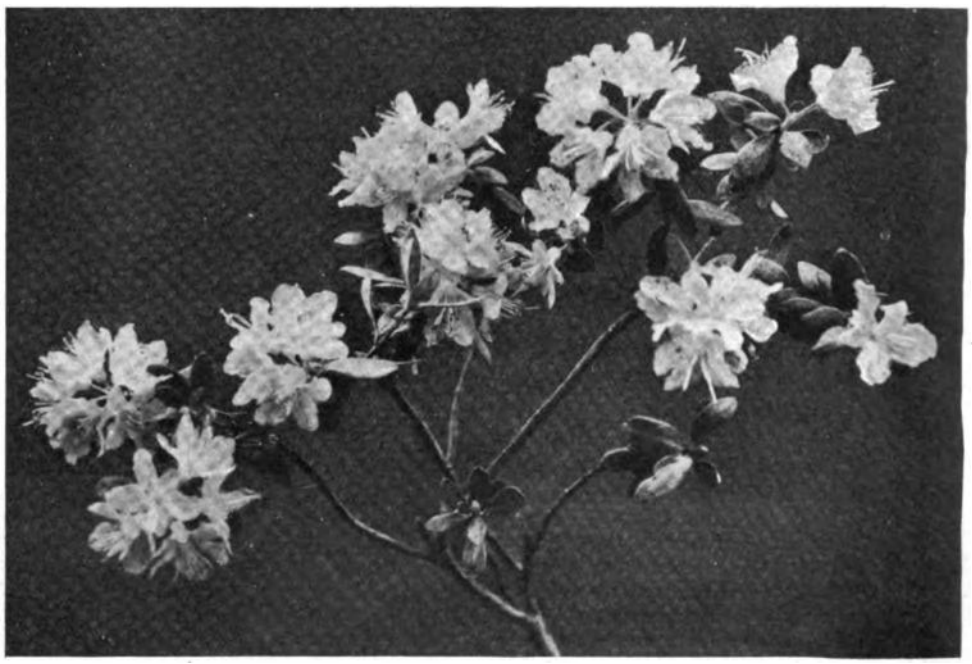
EARLY SPRING FLOWERS AT VINCENT SQUARE

VISITORS to the Royal Horticultural Society's Hall, Westminster, on January 29 must have found it difficult to realise that the drivers of the main line railway trains had "downed engines," for there was a better show than is usual in January, and there was also a large attendance.

Spring flowers, forced of course, were there in plenty, so that the hall presented a gay and festive appearance. The premier exhibit was a gold medal collection of hyacinths, tulips and daffodils arranged by Messrs. Sutton and Sons with their customary skill and taste. This delightful group was very extensive and, especially so early in the season, the flowers reached a high standard of excellence. Hyacinths were perhaps the very best, and these represented the four distinct classes—the large-flowered, the graceful "cynthellas," the multiflora hyacinths and the white Roman hyacinths. The multiflora hyacinths are particularly valuable for general decoration, as each bulb will easily produce upwards of twenty quite good spikes of flowers of all the hyacinth colours. The splendid vases and bowls of large-flowered spikes were the result of the special preparation given to selected bulbs, so that, if desired, they will flower as early in the season as Christmas. Among the very many varieties of splendid tulips Messrs. Sutton and Sons included their White Forcing, Cottage Boy, Keizers Kroon, La Reine, Montressor, Proserpine and Vermilion Brilliant.

A smaller, though graceful, display was made by Messrs. Carter and Co. with large shallow baskets of various hyacinths, Iris tingitana and excellent varieties of the dainty little Primula malacoides. Messrs. R. and G. Cuthbert set up many pots of good hyacinths with most fragrant freesias and desirable clumps of Christmas roses. A good collection of multiflora hyacinths was staged by Messrs. P. Hopman and Sons. These were single bulbs in 5in. pots carrying from six to ten spikes of bloom.

Irises were freely shown, and, besides the vases in Messrs. Carter's collection, I. tingitana was included with their greenhouse cyclamens by Messrs. John Peed and Sons. Messrs. Waterer, Sons and Crisp planted Iris stylosa and I. Sindpers with pretty little hardy cyclamens in their small rockery, and Messrs. Carter Page and Co. also had irises and hardy cyclamens.



THE ROSY MAUVE RHODODENDRON SCINTILLANS.

An interesting selection of the pretty little cyclamens was shown by Messrs. Barr and Sons in a selection of border and alpine flowers. Messrs. J. Cheal and Sons had a small rock garden thinly planted with forced alpines and early bulbs. Hamamelis arborea was shown by Messrs. Skelton and Kirby, and Mr. F. G. Wood had a restrained rock garden and his miniature gardens. The latter type was also shown by Miss Gladys Howse.

The first large-flowered rhododendrons of the year were displayed by Messrs. R. Gill and Son, who had good trusses of RR. argenteum and Nobleanum, with arum lilies and sprays of Erica codonoides. Small branches of Rhododendron Hodgsonii and R. Elizabethæ, bearing luxuriant leaves, were included in a miscellaneous collection by Mr. G. Reuthe, who also staged several green-flowered hellebores and a selection of alpines.

Very well grown little conifers of the type valued for planting in the rock garden were contributed by Mr. G. G. Whitelegg, who also had skimmias bearing a profusion of brilliant berries. In the corner near the orchid annexe Messrs. W. Cutbush and Son arranged a neat rockery and planted it with Pernettya mucronata, Daphne Mezereum, Christmas roses and other plants. Well flowered indica azaleas and Prunus triloba were shown by Messrs. L. R. Russell, Limited.

Carnations were present in their accustomed quantity and brightness. Messrs. Allwood Brothers, who also had their graceful Dianthus

Digitized by Google

Allwoodii, showed such sorts as Marion Willson, Topsy, Chintz, Edward Allwood and Jessie Allwood. Mr. C. Engelmann staged Tarzan, Cupid, Laddie, Red Ensign and other sorts. Such good pink varieties as Eileen Low and Mrs. T. Ives were displayed by Messrs. Stuart Low and Co., and they had an adjoining collection of plants of Acacia Baileyana and a few other hard-wooded plants. Mr. John Klinkert again brought topiary specimens.

A very uncommon fruit exhibit was made by Mr. J. C. Allgrove, who brought splendid bush trees of Apple Ontario in pots. These leafless little trees still carried excellent fruits, illustrating their keeping qualities. He also had dishes of the Canadian variety, which is said to be a good general utility apple, and also showed fine dishes of Cox's Orange, King of Tompkin's County and Newton Wonder.

Messrs. George Bunyard and Co. had some baskets of brilliantly coloured apples. The chief varieties were Allington Pippin, Mabbott's Pearmain, Belle de Boskoop and Heusgen s Golden Reinette.

The garden sundries included a selection of Mr. Pinche's excellent everlasting labels, the Neeta label, gardening gloves, the Letchworth wall frame, the House and Garden seed sower and other appliances; and garden statuary by Messrs. Sander and Co.

Paintings of flowers and gardens were not so numerous as at recent meetings, but interesting pictures were shown by Miss Maude Angell—who also had dainty miniatures of gardens—Miss Winifred Walker, Miss G. Dorrien-Smith, Miss Alice Wilkinson and Miss Ellen Warrington.

NEW AND RARE PLANTS.

Carnation Freddie Ward.—In every way this is a good perpetual-flowering carnation. The shapely flowers are of good size and are borne on long, stiff stems, and the plants showed it to be a robust, free-flowering variety. The colour is a good clear crimson rather deeper in shade than Triumph. The petals are smooth edged and the flowers are deliciously fragrant. Award of merit. Shown by Mr. G. Carpenter.

Gladiolus Melleri.—Judged by the standard of the summer-flowering varieties, this would have little beyond its bright rose scarlet colour to recommend it. The habit is slender, and the flowers are few and small. But if the present is its normal flowering season, this novelty is very welcome and, in addition, we should expect it to have distinct value as a parent—the exhibitor informed us that he has other similar varieties. It was found on boggy ground at an elevation of 10,000ft. on Mount Kenya, British East Africa. The hooded flowers suggest Gladiolus primulinus, and it may be termed a very early, half size, rose scarlet G. primulinus. Award of merit. Shown by Mr. L. van de Weyer.

Rhododendron scintillans.—This belongs to the pigmy type of rhododendron, and its chief value is its early flowering out of doors. The pretty little trusses are a clear purplish rose colour. Award of merit. Shown by Lady Aberconway.

Odontonia Sheila.—The spike bore several handsome well formed flowers of clear brick red colour relieved by light flushing on the tips of the sepals and petals and a white margin to the lip. Award of merit. Shown by Mr. H. T. Pitt.

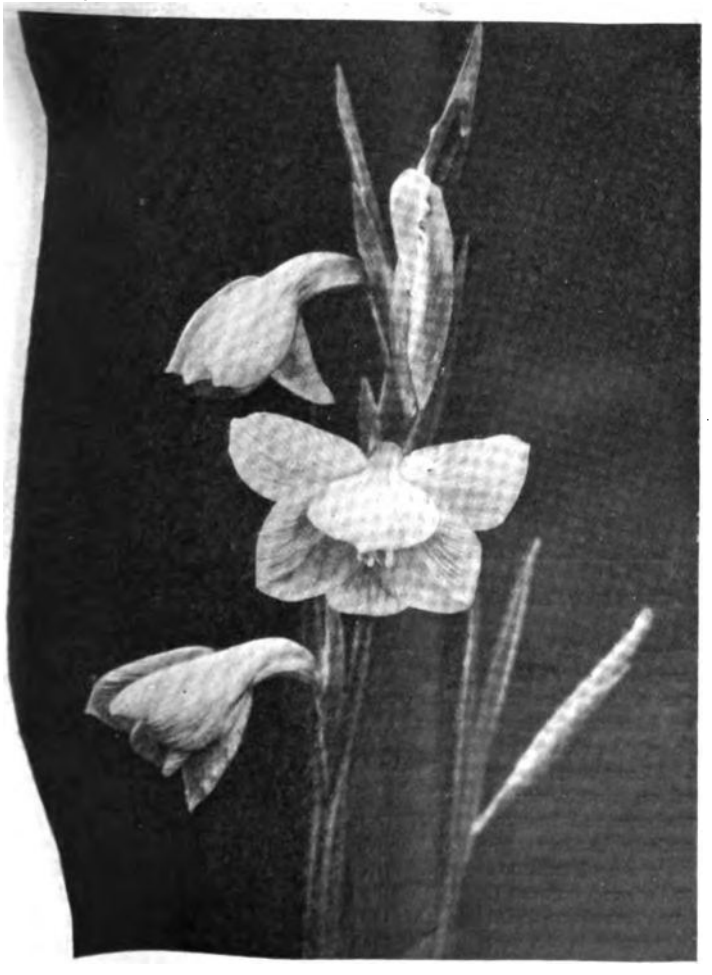
RHODODENDRON NOTES

THIS is the time of year when rhododendrons should be left in peace; although I am accustomed to play tricks with them at other times of the year, yet I never attempt to move them during January or February, when all root action is at rest.

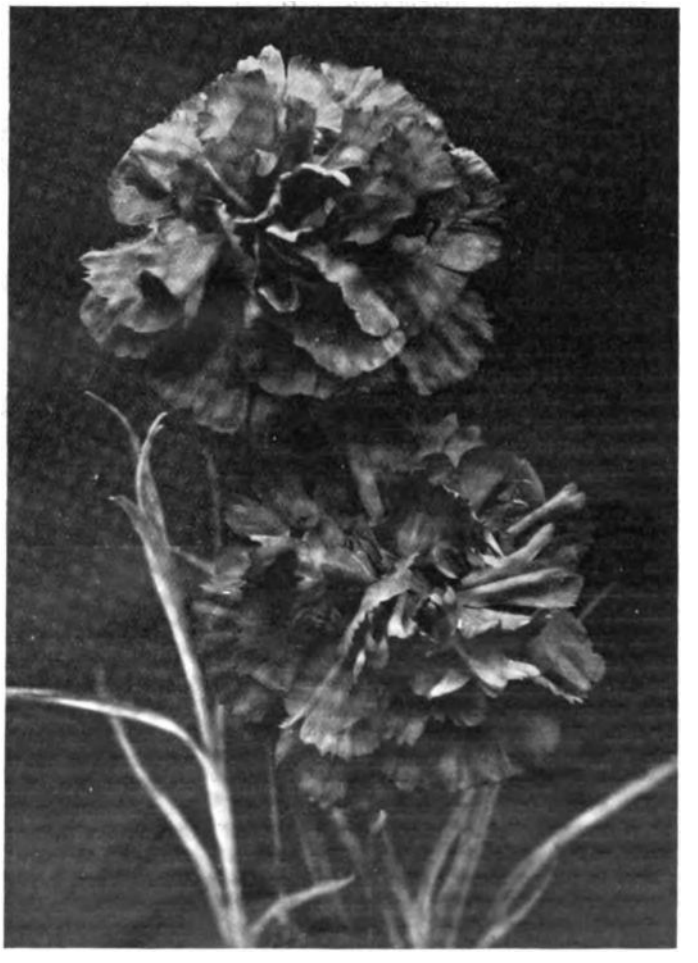
The dwarf species, such as the lapponicum series, have a habit, even inside a house or a frame, of drooping and of turning in colour to a dingy browny purple, which makes one imagine that they will never lift up their heads again. They will recover on the approach of spring or pseudo-spring, if they are kept moderately dry to prevent them from damping off.

In the case of seedlings planted outside, it should be remembered that it is a cold blighting ground draught which causes so many casualties while the plants are small. Once a seedling is 3ins. off the ground, if it is going to do at all, it is moderately safe. If your smallest seedlings in the nursery are showing signs of browning, it is as well to cover them entirely with dead leaves, so that nothing can be seen of them. On the other hand, it is a great mistake to coddle rhododendrons. If a common rhododendron is sick, throw it out, as they are extremely difficult to bring back into good health once they are ill.

A very rare plant is occasionally worth nursing. It should be brought into a house and planted in a pot or tub with plenty of room for root expansion. The soil should be enriched if possible with peat, but should not be so stiff that water will not drain away fast enough. All dead wood should be removed and the plant rigorously cut back with the exception of one or two healthy buds. E. C.



GLADIOLUS MELLERI FROM BRITISH EAST AFRICA.



THE NEW CLOVE-SCENTED CARNATION FREDDIE WARD.

CORRESPONDENCE

THE GENUS ALLIUM.

THE genus allium consists of nearly 300 species, we were told on page 4 by "W. I.", so, naturally, in his useful article he was able to describe some of the more important only. But there are two others among the small alliums I should like to mention as particularly worth cultivating. The first is A. sibiricum which Linnæus described as a species, though it has sometimes been regarded as a variety of the common A. Schœnoprasum, L. Its beautiful bright rose-coloured flowers on quite short scapes are very elegant, and it is a more satisfactory plant than the larger and much paler A. roseum of Southern Europe, though that species has its charm. Many years ago I grew A. sibiricum from Cornwall on a rockery in a Somerset garden, but too much in shade and damp, so that some of the plants became a foot high and lost a little of their colour. In a dry, sunny position it should retain its normal compactness and brilliant colour.

A. Chamæmoly is a very dwarf and curious little species with three or four dull white flowers in umbels not two inches above the ground, and often almost lost in the sand in which it grows in Provence and other Mediterranean regions, where it flowers in January and February. The linear-lanceolate leaves are grass-like and hairy, and altogether it is a very distinct and interesting little bulbous plant which will grow in ordinary sea-sand in the South of England.

May I extol the beauty and easy growth of A. triquetrum so "well worth naturalising in the fern garden," as "W. I." says, or in an open shrubbery or woodland with plenty of moisture. It will also do well on the bank of a ditch, or stream. In Britain it is probably native in Cornwall, where it is somewhat widely spread. In Algeria it is cultivated as a vegetable. There is an old west country proverb which says:—

"Eat Leeks in Lide (March) and Ransons in May,
And all the year after physicians may play."

So the French are not alone in their appreciation of garlic!—H. S. THOMPSON.

FREMONTIA CALIFORNICA.

ALTHOUGH introduced nearly a century ago this singularly attractive shrub is still rare in gardens. This is the more surprising when one realises that it is hardy enough as an open-ground shrub in any of our westerly counties. Here it has withstood 20° of frost, losing only a few of its leaves, but it can generally be relied upon to come through any average winter with its full foliage unimpaired.

F. californica comes from the lofty foot-hills of the Sierra Nevada where it grows on the sunny flanks of rocky canons in sharply-drained soil, but the finest specimens (up to 20ft. high) are said to inhabit the eastern slopes (*i.e.*, the desert side) of that mountain range. In this country it is usually seen as a thin-habited shrub, 6ft. to 10ft. in height, with somewhat stiff, straight branches which, when young, are thickly coated with a scaly felt. Though the leaves are larger in California I have never seen them much above the dimensions of a good-sized gooseberry leaf with us. They are a dull green, normally three-lobed, thick of texture, slightly hairy above and felted beneath with a pale brown fur. The flowers, produced in early summer at the leaf axils on the old wood, are very short-stemmed and consist of a cup-shaped, five-parted calyx in a burnished buttercup-yellow, all glistening with golden hairs, the centre being filled with conspicuous clusters of orange stamens. These blossoms stand rough weather remarkably well, they last long and are often produced in such abundance that the foliage is almost entirely hidden by them. Seed is set freely and these afford the best means of increase.

In regard to the generally accepted belief that F. californica is a short-lived plant, it is interesting to note that in its own country this shrub is considered very averse to being watered during the dry season. Is it possible that planting against a south wall, as we often do, together with the practise of watering which we frequently indulge in, may be the cause of its dying-off while still young?—CAMBRIA.

SAXIFRAGA OPPOSITIFOLIA AS A MORAINE PLANT.

IT is, I think rather remarkable how few of our native alpines one sees grown with much success in gardens. Everyone grows Gentiana verna, but few make a success of it, and the native plants (usually inferior in quality to those from European Alps), do no better than those from imported stocks. Undoubtedly the gentian, in common with the charming Androsace Chamæjasme, suffers from the isolation to which it is subjected. Some kind of associated planting, such as Arenaria verna, is indicated for both.

SAXIFRAGA OPPOSITIFOLIA, AN ATTRACTIVE NATIVE ALPINE.

Saxifraga oppositifolia, however, in its many beautiful forms, is a much more amenable plant and few fail to grow and flower it. Yet it seldom looks really healthy and has a nasty habit of becoming bare in the middle of the clump and requiring frequent replanting. I have come to the conclusion that when planted on a rock garden ledge it is usually given too much sun and drought. Sun, no doubt, it gets in abundance in the mountains, but there is there no shortage of moisture. This, I fancy, is the reason for the good account it gives of itself in the moraine, and there is no doubt that where space permits, the moraine is the best place for it, along with the minute and charming (and closely related) S. retusa. I think the variety called coccinea is quite the best of the coloured forms of S. oppositifolia, but I do not agree with the late Reginald Farrer in his depreciation of the white variety, which, though starry, is very beautiful.—N. H. P.

A BEAUTIFUL PURSLANE.

AMONG the rock purslanes there are few, if any, better than Calandrinia grandiflora, a plant which is distinctive and beautiful enough to stand out as one of singular merit even among the many rivals which the lists of half-hardy annuals afford. This is a Chilian species and one that can easily be raised from seed sown in the open ground where the plants are to flower. But as it needs a warm, gritty, poor soil, those who cannot give it such accommodation may find it safer to sow indoors and move the seedlings out in May. Earlier blossoming will at any rate be secured in this way, though in our gravelly hot soil and genial climate we can get seedlings raised by out-door sowing in spring to flower in August.

C. grandiflora makes rosettes of long, narrow, fleshy leaves of a pale, glaucous green, usually tinged with purple. From the centre of these rises a stout but elegant stem to the height of a foot or more, and this bears at the tips of its branched extremities single flowers, about 1½ins. across, of an exquisitely delicate texture and a pure, bright rose with a centre of golden anthers. All the plant seems to need is as much sun as possible and the poorest of soil. Yet in spite of all these good qualities and the fact that about a thousand seeds can be secured for twopence, C. grandiflora is comparatively rare in the average garden.—N. WALES.

ASPARAGUS PLUMOSUS AS A POT PLANT.

UNTIL just recently I was quite unaware that the above plant would thrive in the atmosphere and surroundings of a cottage window. But one of the men here has given me ample proof that such is the case, inasmuch as he has a good specimen in a 7-inch pot, and this plant has been growing in one of the windows of his house for several years. It is quite healthy and a good colour, too.

Digitized by Google

Is not this experience somewhat unique? I have always thought this plant required a moderately warm house, to say the least—and it is often found placed in quite hot temperatures—yet the above instance would seem to show it is possible to grow Asparagus plumosus under cooler conditions with splendid results, though no doubt the progress of the plant is slower when so grown. Has any reader ever known this foliage plant living in similar environs before?—C. T., *Ampthill.*

CAMPANULA LINIFOLIA AT MONT CENIS?

IN connection with the article "Alpines from the Pass of Mont Cenis" in the issue for December 8th, 1923, I have been puzzling over two points, and I should be glad if the statements might be confirmed. The first is with regard to the photograph of "Silene alpestris in the Alps." It is difficult to make out sufficient detail, but the photograph clearly shews this to be a flower of four petals. I believe silenes are always five-petalled, and in addition the petals of Silene alpestris are each toothed with four or five teeth, giving the bloom a fringed appearance. In addition Silene alpestris is an Eastern species, belonging to the Carpathians and the Alps east of the Dolomites, and does not belong to the French Alps. [The title under the picture was a slip (since corrected, page 670) for Silene acaulis.—ED.] The second point is in regard to Mr. Lofthouse's statement that he found Campanula linifolia on Mont Cenis. I do not question Mr. Lofthouse's accuracy, but, if linifolia is actually to be found there, it is a point of considerable interest. Thompson gives Campanula linifolia (Scopoli) as equivalent to C. carnica (Schiede), as being sometimes regarded as a variety of C. rotundifolia, and as being found in Carinthia only. Flahaut, on the other hand, gives C. linifolia as a species found in the Alpes of France and also as being akin to C. rotundifolia. But Thompson's linifolia is an entirely different plant from Flahaut's linifolia, and the figure of linifolia given by Flabaut bears no resemblance at all to rotundifolia. The maximum altitude of Flahaut's linifolia is given by him as 1,800 metres, and Mr. Lofthouse was considerably higher than that. This linifolia is very near to C. lanceolata of the Central and Mediterranean Pyrenees. Now what I should like to know is, whether the C. "linifolia" vouched for by Mr. Lofthouse on Mont Cenis is Thompson's linifolia or Flahaut's linifolia, or was it in reality C. rotundifolia? I mention the third alternative because it used to puzzle me why C. rotundifolia was so named and not named linifolia, until I discovered that the round, radical leaves of rotundifolia die away before the plant flowers. I seem to remember—I have not the book at hand to refer to—that in John's classic on English wild flowers, it is stated that "rotundifolia" is a misnomer, and this mistake—pardon me, if I forget—has not been corrected in the new edition by Mr. Clarence Elliott.—E. ENEVER TODD.

PETUNIAS AND VERBENAS FOR BEDDING.

I WAS much interested last summer in the behaviour of petunias and verbenas bedded out in the ordinary way in June, and other plants simply submerged in their pots and their roots restricted. The former owing to the abnormal amount of rain became rampant in growth, and it was not until quite late in the season that they bloomed to any extent. The pot-bound plants, on the contrary, commenced to flower early and made the beds quite showy, their cramped condition pushing them into bloom.—W. LINDERS LEA.

[Quite so; but suppose the season had turned out something like 1911 or 1921? Meteorology will have to be a fairly exact science before most of us will care to "bed out" in the way suggested. —ED.]

REMARKABLE FOR ITS MAGNIFICENT FOLIAGE, SPIRÆA MILLEFOLIUM.

GODFAYTHERS.

YOUR note to the correspondence on "Godfaythers" (December 29, 1923, page 679) I can corroborate, as I have heard it used both in Suffolk and Hertfordshire, but in the latter county the word "lawyer" is in more common use—meaning a prop or support to a badly built hay or corn stack. I doubt, however whether the two words are really synonymous.—J. H. KITTON, *Enfield.*

SPIRÆA MILLEFOLIUM.

ALTHOUGH perhaps not quite so attractive from a flowering point of view as some members of its extensive genus, this is certainly one of the most remarkable and interesting species. It is chiefly notable for its magnificent foliage. The leaves are from three to four inches long, bipinnate and their minute sub-divisions give them a strong resemblance to our common milfoil (Achillea Millefolium). The upper side of the leaf is greyish green, the undersurface covered with dark tomentum, while the petioles and midribs as well as the young wood are covered with a viscid gum, which gives off a strong pungent aromatic odour, said to resemble that of creosote.

An erect growing bush from three to six feet high, producing during July erect, terminal branching panicles, from five to six inches long of short-pedicelled white flowers with conspicuous yellow stamens, each individual flower being about half an inch across the flower stalk and the calyx covered with stellate hairs. This plant might be considered evergreen, although the leaves during winter are rather small and restricted to the extreme tips of the shoots.

It is distinct from all other shrubby spiræas by reason of its much divided foliage and is sometimes placed in a genus of its own as Chamæbatiaria Millefolium. Apart from its divided foliage, there are other minute differences, such as the way dehiscence of the seeds takes place, the shape of the seed, and so forth, but these are not generally considered sufficient to separate it from Spiræa. It is very similar in appearance to chamæbatia foliosa, and in Nicholson's Dictionary is given as a synonym of that, but the leaves of Spiræa Millefolium are bipinnate, whereas in chamæbatia the leaves are tripinnately dissected, while the flower structure is different. It was first discovered in 1853 by Dr. Bigelow in West Arizona, but has since been collected on the Sierra Nevada of California, and at an elevation of 10,oooft. in South Utah, and as far north as West Wyoming territory.

Here at Cambridge it is quite hardy, the dry atmosphere and soil being apparently what it requires. It should be planted in an open sunny position, and if the soil is too rich it encourages vigorous succulent growth which is likely to be injured during a hard winter. It is readily raised from seed, or from cuttings of half-ripened wood taken with a heel in August, and placed in a little bottom heat. Although introduced into this country as long ago as 1880 it is not common in gardens.—F. G. PRESTON, *Botanic Garden, Cambridge.*

WHITE GENTIANS OF THE ACAULIS SECTION.

REFERRING to your footnote to M. Correvon's "Notes from Floraire," (p. 18) last year my wife found and sketched a white gentian of the acaulis type which is clearly G. excisa (Kochiana). This was found above St. Gervais-les-Bains in Haute-Savoie. It was, however, only the whitest of a number of forms found at the same time which might be called "cœlestina." The coloured sketch shows that it was very clear white and very beautiful.—E. E. T., *York.*

THE FIFTY BEST ALPINES.

I NOTICE with interest "Purley's" reply in THE GARDEN of January 12 to my queries on his list of "Fifty Best Alpines." I see he is

Digitized by Google

plagued with the same old enemies of alpine plants, namely, cats and slugs. Much disappointment would be avoided if we could rid ourselves of these. Does he notice what a lot of damage worms will also do? If he takes a look round his rockery after dark with a light, he will see worms coming out of the centre of many of his choicest small plants, especially Kabschia saxifrages. In doing this they eat their way through the crown of the plant and lift it right out of the soil. Then they proceed to drag the leaves of all plants within reach down the hole thus made. They also nibble off the young shoots of choice plants just as much as slugs do. I do not think "Purley" need hesitate to include Wahlenbergia vincæflora on his rockery. I grow it on my limestone moraine, where it is very happy and seeds itself freely. The flower-stems are only about 10ins to 12ins. high, and are very numerous. It blooms for a longer period than any other plant I have, beginning in June and usually continuing until the frosts cut it down, when it disappears until the following spring. The flowers are very pretty, of a pale blue colour and suggestive of an intermediary between a campanula and a periwinkle on thin wiry stems. "Purley" remarks that he does not know Dianthus gallicus or Polemonium carneum. The first is rather straggly, but atones for that fault in being the last of the pinks to come into flower, and also for its delicious scent. It commences to flower in August and continues until the frost cuts it. I have plenty of seed of it if he would care to try it. With regard to Polemonium carneum, I think it is one of the most distinctive of its race. The flowers are much larger than in any other Polemonium I know, and are of a lovely delicate flesh pink colour with a pale yellow eye. The plant seems to be quite easy and grows well anywhere. It blooms in June.—H. STEWART WACHER, 9, *St. George's Place, Canterbury.*

A CHARMING GRASS.

VARIEGATED foliage in ninety-nine cases out of a hundred looks best by itself, that is to say, when the flowers are so inconspicuous that they are never noticed, or when none is allowed to develop. The day of variegations has to a large extent gone by. The present generation of gardeners know not the famous "Mrs. Pollock." In the sixties and seventies of last century it would have been unnecessary to say more. To-day it is as well to state that Mrs. Pollock was the high water mark of tricoloured Zonal Pelargoniums. In gardens it was flowerless. Only in establishments where new varieties were sought after was the plant allowed to bloom. It was a wise restriction. Grasses are, obviously, a very different proposition from flowering plants, and in my humble opinion are the "very thing" for variegations. Mr. James MacDonald's smart-looking "all grass" exhibits proclaim the pleasing effect of different varieties suitably combined together and introduce us, if we look carefully at his groups, to some which we would find useful in an ordinary border of flowers. Among low-growing Grasses from 9ins. to 1ft. in height none, to my way of thinking, is as beautiful as Arrhenatherum bulbosum fol. var. There is a peculiar freshness and spruceness about its general appearance which is most attractive. The white and the green are such a good match for one another, and yet the contrast is very marked. There may be more than one strain of variegated-leaved Arrhenatherum bulbosum, so it may be as well to say that my plants came from Mr. MacDonald. It is so beautiful I would like to add to its already ponderous name Macdonaldi. It is worth it.—JOSEPH JACOB.

HOW TO OBTAIN GARDEN PEAS FROM JUNE TO OCTOBER

TO grow peas satisfactorily it is essential that the soil be properly prepared. Deep digging or trenching always gives good results even in the case of poor, gravelly ground. Well rotted manure is essential to success in the latter case to produce ample haulm according to the variety. A variety that should grow to a height of 3ft. will not be an economical plant at 18ins. high. If the plant is forced to a height of 4ft. or more through the use of rich organic manure or on account of the position being unduly shaded, it will not be a profitable plant. Haulm will be produced, but no flowers or pods in profusion. Peas enjoy an open position, and judicious feeding will be beneficial. About 6lb. per square rod of basic slag in the autumn, and 2 oz. of superphosphate per yard run of row, when the plants are about 3ins. high, will do a lot of good. To assist in the filling of the pods with good peas, dissolve 2 oz. of phosphate of potash in rain-water and apply at the rate of a gallon per 5yds. run of row when the majority of the pods are just formed. On light soils early surface mulching of the rows with litter, lawn grass or similar material will help to conserve moisture.

The trenches should be made at least 18ins. wide for each row. The rotted manure should be thoroughly mixed with the soil to a depth of 16ins.; there need not be any manure nearer than 5ins. to the surface, then the plants will be able to withstand a spell of dry weather—it may be just when they are beginning to flower. It is wrong to place rank manure, unmixed with the soil, in a very narrow trench.

SITE FOR EARLY CROPS.—There is no position in the garden more suitable than the raised border with a wall or adequate fence on the north side. This border may be a narrow one 7ft. to 10ft. wide; but the rows should run due north and south.

SOWING THE SEEDS.—The distance between the rows must be governed by the approximate estimate of height of each variety grown. The same distance between the trenches as the height—thus: the variety grows 2ft., or 4ft. 6ins., and so on—in cases where a number of rows are grown together.

Where a border is devoted to early, dwarf-growing sorts, I prefer to dig and manure equally the whole of the soil; then a flat-bottomed drill, the width of the spade and 3ins. deep, is readily made. The round-seeded varieties claim first attention and should be evenly sown, the seed being nearly 2ins. apart. Where mice are troublesome the seeds should be moistened and then rolled in red lead. Place on them half the soil removed from the trench.

Although early peas are appreciated the main crops are the most important and big crops cannot be grown unless full justice be done to the plants. If there is only room for four rows fully to develop in, do not attempt to grow six. The isolated rows—those grown about 9ft. apart with early potatoes or spinach between, are the most satisfactory. The crops named do not interfere with the welfare of the peas, but cabbages, winter greens and all of the Brassica tribe do, and should not be planted near peas, dwarf or runner beans. The same process applies as regards sowing as in the case of early varieties, but the seeds should be 2ins. apart in the flat-shaped drill; and 3ins. of soil will not be too much to place on the seeds on account of probable dry weather coming before the flowering stage is reached.

Two lots of sticks should be placed to each row; first, the dwarf fan-shaped ones directly the plants appear through the soil, and second, the taller ones when the plants are 6ins. high. The sticks should be driven into the ground firmly and in such a way that the tops will be about 1ft. apart. If the sticks meet in a point at the top the haulm grows through the sides two-thirds of the way up, and so fails to get the support it requires.

Peas rarely do well in dry weather if they are constantly soaked with cold water; a bad attack of mildew often being the result. The better plan is to apply a substantial mulch after a heavy rain, or before the soil gets very dry; or, in the absence of rain, immediately after a thorough watering.

Dustings of lime or soot, not the two together, will help to preserve the young plants from attacks by the weevil and fly, also sparrows. The plants are at their best at the time when young sparrows are numerous and these are not easily scared away. Netting good rows is worth while.

Strings stretched just above the rows, with pieces of glass attached at intervals, will help considerably. The pieces of glass should be securely fastened to the ends of short lengths of string, the twine depending from the overhead line.

The topping of the late crops will help in the matter of pod-filling. Only a few inches should be cut off and resultant lateral shoots should be pinched out, too. Standard varieties only are named as a guide in the following list:

Early Varieties.	*Date of Sowing.*	*Approximate Height.*	*Crop Matures.*
Pilot	February	24in.	Early in June.
English Wonder	Early February	18in.	Middle of June.
William Hurst	Mid-February	15in.	Middle of June.
Gradus	End of February	36in.	Late in June.
William The First	End of February	36in.	Late in June.
Telephone	Early in March	48in.	Early in July.
Duke of Albany	Early in March	48in.	Early in July.
Fillbasket	Mid-March	36in.	Middle of July.
Senator	Mid-March	36in.	Middle of July.
Gladstone	Mid-March	36in.	End of July.
Ne Plus Ultra	Late in March	60in.	End of July.
Latest of All	April to June	36in.	August and September.
Autocrat	April to June	36in.	August and September.
Early variety again for latest use	Late in June	16ins. to 30ins.	September and Early October.

GEORGE GARNER.

Digitized by Google

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Peas.—Provided the ground is in a suitable condition, a liberal sowing of an early kind may now be made, choosing such sorts as Gradus, and Early Giant. Sow Pioneer if a dwarf variety is preferred. A warm and fairly dry part of the garden should be chosen and ample space allowed between the rows. Gradus and Early Giant may be planted in lines 3ft. or 4ft. apart, and to counteract losses from slugs and mice sow rather thicker than usual.

Potatoes.—If brick pits are available they may be utilised for early potatoes. A mild hot bed containing plenty of leaves is an advantage and 9ins. or 10ins. of light soil will be needed. The rows should be 18ins. apart and the distance between the sets 9ins. Well sprouted tubers are best, and the most suitable varieties are May Queen, Midlothian Early and Sharpe's Express. Due attention should be paid to ventilation to prevent the growth being drawn and weak. Tolerably good crops may be obtained from pot culture. Receptacles 9ins. or 10ins. in diameter are recommended and two tubers placed in each pot. For a start only fill the pots half their depth with soil.

Shallots.—Good results may be obtained by planting these now. Place the bulbs in rows 1ft. apart and 8ins. asunder. Do not entirely cover the bulbs, but press them in the soil so that they are held firm and partly buried.

Parsnips need a long season of growth, so an early opportunity should be taken to sow the seeds. Student and Tender and True are both reliable and the seeds should be sown in lines 15ins. to 18ins. apart and about 1¼ins. deep. Deeply dug ground which was well manured the previous season is best for this crop.

The Flower Garden.

Phlox Drummondii.—The large-flowered strains of this beautiful annual are well adapted for bedding purposes, large patches in the borders, and filling up gaps on the rock garden. Sow the seeds in boxes containing light soil, and raise the seedlings in a warm greenhouse, afterwards grow them as cool as possible. When the seedlings are large enough to handle prick them off 2ins. apart. Boxes will suffice if only a small number is required, but for large quantities cold frames will be needed. When the seedlings begin to grow freely pinch out the centres to produce bushy plants.

Phacelia campanularia is one of the best blue annuals and two or three sowings should be made during the season. On a dry warm border seeds may be sown now, but the main sowing should be deferred till March or April. It is an ideal plant for the rock garden.

Pentstemons.—The forms known as Newbury Gem and Southgate Gem are largely grown in borders, but the bedding qualities of the large-flowering varieties are not so much appreciated as their merits deserve. They can be obtained in various shades of colour and if seeds are sown during the next week or two good plants will be secured for the beds later on. A little heat will be needed to raise the seedlings, but afterwards they should be grown fairly cool.

Dahlias.—The tubers that were not lifted last autumn may now be removed from the shed and placed in a warm greenhouse where they will produce a quantity of shoots suitable for cuttings. There is no need to bury the roots, but it is advisable to sprinkle a little old potting soil among them, and they should be kept moist. When growth is evident the roots may be divided and sufficient cuttings propagated to make good any losses or to increase the stock of special varieties.

Fruits Under Glass.

Fruit Trees in Bloom.—In some seasons both Peaches and Nectarines occasionally fail to set a satisfactory crop and several instances last year came to my notice. A frequent cause is the border being dry during the autumn months, but I am inclined to think that climatic conditions are more often to blame. A temperature near freezing point and a moist stuffy atmosphere are not conducive to the proper development of the flowers and more particularly the pollen grains. On the other hand more favourable conditions are created by raising the temperature by mid-day to 50° Fahr., with a few degrees lower during the night. Keep the trees dry and admit a little air whenever the weather is favourable. No damping down will be needed unless the sun is very bright, and then the borders and paths may be lightly sprinkled with water during the afternoon. Remove any weak or badly placed flowers and about mid-day pollinate the blooms, using a small, soft brush, or a rabbit's tail tied on a bamboo cane. It is always advisable to vaporise the house just before the flowers open to destroy any aphis that may be present and afterwards the trees should be watched for both green and black fly or the young tender shoots will be ruined.

Strawberries.—Plants that were placed on a mild hot bed some weeks ago are showing their flower trusses, and in consequence syringing will cease and the temperature be kept at about 55°. Remove the plants to a light position in a low house or on a shelf and pollinate the flowers at mid-day. When the fruits are set, thin them to six or nine on each plant, and continue to syringe them with tepid water until the fruits commence to colour. During the swelling period the night temperature ought not to fall below 60° and the roots should be fed with soot water, and some reliable fertiliser, such as Le Fruitier, or Thompson's. To keep up the supply another batch should be introduced. Pot Strawberries should never suffer from lack of moisture at the root. Both red spider and aphis should be held in check.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castle'ord, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—A sowing should be made now. Take out rows—preferably running north and south—6ins. wide and 3ins. deep. Place the beans in two lines 4ins. apart; 3ft. between the rows will be found ample space for most varieties.

Asparagus Bed.—Young plants are usually set out, or seeds sown in beds, 4ft. broad. These should be well prepared before planting or sowing. In heavy soils, throw out the earth to a depth of 2ft., and lay the bottom with stones and old bricks, over these place a good layer of rough strawy manure, then add a layer of manure to a depth of 8ins. Soil and manure well mixed should constitute the next layer, which, after firming should bring the bed nearly up to the level. A soil layer of a few inches should complete the bed. At seed time there should be space on a bed of this size for three rows 15ins. apart.

Seedlings.—Cabbages and cauliflowers should now be pricked off into boxes, or into frames. Tomatoes should be placed into small pots. Sow cucumber seeds in small pots and, with the young tomatoes, place in a genial heat.

Rhubarb.—In time the plants become large and the centres barren and bare, this indicates that replanting is necessary. Dig up the roots, separate the crowns, and make certain that each crown has a good portion of root. Replant about 3ft. apart in well trenched and manured soil.

Potatoes.—It is stated by the Ministry of Agriculture that the planting of any other than immune varieties of potatoes in private gardens or allotments in Scotland is prohibited. Non-immune First Early Varieties may be planted if a permit is obtained from the Ministry.

The Flower Garden.

Delphiniums.—These stately plants thrive best in an open position and a rich soil. Where a border or portion of ground is set apart for the plants, the work of trenching or enriching the soil is easily done, as the plants can be lifted and set to one side while the ground is being trenched and manured. If the plants in herbaceous borders look at all poor they should be lifted now, and the stations enlarged and deepened. In the bottom of each hole place a quantity of rotted manure, then a few inches of soil and replace the plants, filling in and around the roots with manure and soil mixed.

Gypsophila paniculata.—The small whitish flowers and finely branched spray formation of this plant might well merit its description as the mist-like plant of the border. A mixture of two parts old lime and sand to one part loam should now be placed as a top dressing among the plants in borders or beds.

Plants for Beds.—Lobelia cardinalis should be divided and the strongest and best shoots placed in boxes containing good soil. Begonia bulbs and gladioli corms should also be boxed. Set out seedlings of East Lothian stocks two or three inches apart in boxes filled with good soil made fairly firm, and place all in a genial temperature. Ageratum, lobelia and the double-flowered nasturtiums should be increased by cuttings and kept in a warm house until rooted.

Turfing.—Occasionally, places around and near flower beds and borders get unlevel. If such should be the case, lift the turf at these places—if not already done—and put down sufficient good sifted soil to bring up to the level before replacing the turves. The edging and digging of the beds—if vacant—should also be done.

Fruits Under Glass.

Melons.—Those with accommodation for growing this fruit should sow seeds now in small pots filled with good loamy soil. Place the pots in a warm pit, or where bottom heat is available.

Peaches.—Give daily attention to the disbudding of the young growths in the early house and where the flowers are properly set, syringe the trees, damp the stages and pathways, and close the ventilators early in the afternoon so as to maintain a genial growing atmosphere.

Vines.—When the vines are in flower, tap the rods daily in the forenoon and maintain a drier atmosphere, damping down less, and especially so in cold, dull weather. Give top ventilation on fine sunny days, and when the temperature of the house is likely to rise above 70°.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

GREENHOUSE AND CONSERVATORY.

Trachelium cœruleum.—This blue-flowered plant is very useful for furnishing the conservatory. The same remark applies to its white-flowered variety. If seed is sown at this time the resultant plants will prove very useful for the stages during late summer and autumn. Plants kept over from last year will make fine large specimens for standing in the beds. For this purpose they may now have a shift into 8in. pots. This plant only requires cool greenhouse treatment at all stages of its cultivation.

Freesias.—Early batches of plants as they pass out of flower should not be neglected at this time. If it is desired to grow them on for future use, they should be given a position in a light greenhouse, or even in cold frames. The plants should be regularly watered until the foliage shows signs of dying off, then water should be gradually withheld. When the foliage has died down, the corms may be left in the pots until required for repotting, or they may be turned out of their pots, sorted into two sizes and stored in dry sand until August, when the first batch should be potted up. Freesias coming on for flower should have a good position in a light, airy greenhouse, and receive regular attention as regards watering, and feeding with diluted liquid manure and guano. Care should be taken to keep the growth properly supported. The same treatment should also be accorded to ixias, babianas and lachenalias.

Calceolarias, of the herbaceous section, raised from seed sown last August, should now be ready for a shift into larger sized pots. These plants enjoy a rich compost, thus some old mushroom-bed manure, or dried cow or sheep manure, may with advantage be added to the potting compost. These calceolarias prefer a moist atmosphere and should be grown perfectly cool at all times. They are very subject to attack by green fly, so should receive frequent light fumigations. Calceolarias of the shrubby section, as represented by CC. Clibrani, Allardii, integrifolia and angustifolia, should be potted on as they require it and pinched several times to induce a bushy habit. Calceolaria Burbidgei is also very useful for the greenhouse, and if a batch of cuttings is inserted at this time they will come in very useful for flowering during the autumn. Plants used in this way for furnishing the benches last year may now be potted on into 8in. or 10in. pots, in which they will make fine specimens for furnishing the beds in the conservatory.

Clerodendron fallax.—This fine plant is generally grown for the stove, to give a display during the winter. It is, however, invaluable for conservatory work during late summer and autumn, and it has the additional merit of remaining in good condition for nearly three months. To obtain plants for this purpose, seed should be sown at this time in a warm house with a temperature of about 60° Fahr. The seed is somewhat slow in germinating, but once it is up the young plants

Biodiversity Heritage Library

grow very quickly. They should be potted on as they require it until they are in 6in. pots, in which they may be allowed to flower. They are best grown in a temperature of 55° to 60° Fahr. until they come into flower, when they will stand quite well in an ordinary greenhouse. This plant can also be propagated by means of cuttings, which root readily in a warm propagating case, but, on the whole, seedlings give the best results.

Clerodendron fragrans, which has double white flowers, is by no means a showy plant, but it is worth growing for the sake of its fragrant flowers. It is easily propagated at this time, either by means of ordinary cuttings or root cuttings. These root freely in a warm propagating case.

Clerodendron Thomsonæ is generally regarded as a stove climber, but grown in large pots it makes fine specimens for flowering in the conservatory during the summer. Where such specimens exist they should have been kept dry and somewhat cool during the winter, but they should now be well soaked at the root, and started in a house with a temperature of 55° to 60° Fahr. All dead and weak wood should be cut out, and the strong healthy shoots trained round neat supports.

Statice Suworowi.—This is one of the best of half-hardy annuals for the greenhouse, and as such is deserving of more general cultivation. If not already done, a little seed should now be sown in a cool house. When large enough to handle the young seedlings should be pricked off into pans or boxes, and later on transferred to small pots. These plants are best grown singly, and 48-sized pots are large enough for them to flower in. If larger specimen plants are required, three plants may be placed in a 6in. pot. This statice requires careful transplanting and watering. Successional batches will keep up a display until late autumn.

Asclepias curassavica is very useful for the greenhouse during the summer and autumn, and seed should now be sown in a warm greenhouse. This is a slender-growing plant, thus the best results are obtained by growing several plants in a pot. If 48-sized pots are favoured, three plants should be placed in each pot and four or five for 6in. pots. This plant may be grown in an ordinary greenhouse temperature.

Fuchsias that were rooted last September and have been kept growing steadily on all through the winter will now be ready for a shift into 6in. pots. The leading shoot should not be pinched, but tied up to a neat stake, as the lateral growth will break naturally. When the lateral shoots have made about three leaves they should be pinched, and this should be continued up to about six weeks before the plants are required to flower. They should be potted on until they are in 10in. pots, and by that time they should have made specimens some 7ft. in height. J. COUTTS.

Royal Botanic Gardens, Kew.

EARLY CELERY

THE successful cultivation of main-crop celery requires much skill, but even more skill is required with the early batches of plants. The chief danger, with regard to early crops is in overgrowing the plants; then the latter either "bolt," run to seed, or the stalks are hollow and pithy. In dealing with early batches, or main-crop plants, the inexperienced cultivator relies on the assistance afforded by cold frames, and so the plants are grown in a comparatively cool and even temperature. In the case of early batches he should rely upon the heat from hot-beds or hot-water pipes, or both. Celery thrives best in a moist rooting medium and a cool temperature. The application of great heat is harmful. Of course, at this season some artificial heat is necessary, and a very good way to apply it is as follows: The seed pan should be well drained, both crocks and pan being clean. The compost should be light to medium: equal parts of leaf-soil and well rotted loam with a dash of coarse sand being an ideal one. This mixture should be made moderately firm, smoothed on the surface and watered; only a few seeds should be thinly dropped evenly on the surface and very lightly covered. A shelf or stage in an intermediate house forms the ideal position for the pan, and the latter should be covered with glass only. When water is necessary, apply it by immersing the pan in tepid water. Remove the glass when the seedlings appear, and transplant the latter at an early stage in a similar compost, retaining the plants in the same position. The next shift should be to a bed in a frame or to deeper boxes. I prefer the frame. A thin layer of ashes should be laid down, then 1in. of rotted manure, and on this 3ins. of good compost, all moderately firmed. The young plants should be carefully lifted and transplanted 4ins. apart each way, and after the first week the frame should be freely ventilated. When the time comes to finally transplant the celery, practically all the compost above the layer of ashes will adhere to the roots and be transferred with them to the prepared trenches. Plants, so treated, will not be checked. But bottom heat, high temperatures, close atmospheres, and careless transplanting, with overcrowding, will result in checks and disappointing crops. HANTS.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

TREATMENT OF IRISES (W. G. S.).—The herbaceous iris thrives best in a rich, loamy soil. By richness we mean deeply dug soil that has not been unduly exhausted by other and grosser-growing crops, and which contains good, well rotted manure—not fresh, organic manures. The bulbous kinds do not require such soils, but do best in a sandy loam; a small proportion of leaf-soil or peat will assist the growth. Old lime rubble, judiciously used, does help matters, it acts on the soil beneficially, breaking and sweetening it.

TREES AND SHRUBS.

PRUNING A HOLLY HEDGE (J. H. P.).—May is the best month to prune a holly hedge when the cutting is to be rather hard. Our correspondent's idea to cut the top and one side this year, and the remaining side next year is correct. Do not cut off more of the thinner branches than is absolutely necessary. Wood as thick as a pencil, or one's little finger, will break freely, but shoots from wood larger than this are irregular and uncertain. Clean the ground at the bottom of the hedge and give a good mulching of old decayed manure. Spray the hedge freely morning and evening on dry days, for a couple of months after pruning.

FRUIT GARDEN.

FIG TREES UNSATISFACTORY (E. S. W.).—As the trees are very old the roots, no doubt, permeate the soil a long way from the main stems. Six feet from the latter a trench should be opened and all main roots cut off at that point. It would be a difficult matter to restrict the roots entirely to that space with a cement underground wall. All such restriction is best done when the trees are first planted. All soft, sappy shoots should be rubbed out while young till the end of August. The next year's fruiting wood would thus ripen. In September pinch off the ends of the shoots retained, and all fruits, as large as Barcelona nuts, should be removed. Stop the ends of the fruit-bearing shoots next year when the fruits are swelling freely. If judiciously summer-pruned, winter pruning will not be necessary.

MISCELLANEOUS.

THE DESTRUCTION OF DUCKWEED (Lady W.).—It is not possible to poison the duckweed without damaging other vegetation. Raking it out at frequent intervals will be found the best way of dealing with it. Ducks will eat it and might, perhaps, be kept.

TO MAKE GARDEN AND TENNIS NETS WATERPROOF (H. A. C.).—First dip the nets in boiled linseed oil; then roll up for ten minutes and hang them up to dry. Repeat this once more. Give a final dressing of boiled linseed oil seven-eighths, and one eighth best copal varnish. Roll up again for ten minutes and hang out in the open air till the nets are perfectly dry. Store in a cool, dry place.

TREATMENT OF "TARMAC" GARDEN PATH (H. A. C.).—Our correspondent should procure some dry sand and small gravel or stone chippings, also tar in readiness for use when the hot weather comes. The tar should be hot when put on in a good substantial layer; before it cools sprinkle on the gravel or stone chips; when almost cold add a generous sprinkling of dry sand and roll all in with a light garden roller. Do not use pitch. An ordinary garden path should have a base of gravel and tar 2ins. thick on which the finishing layer of tar, gravel or stone chips is placed.

HOW TO SCARE WOOD PIGEONS AND MAGPIES (G., Dublin).—These birds are very cautious if once trapped or badly scared. Shooting would not keep wood-pigeons away as they will return regularly if the gunman is not visible. But as shooting is not possible our correspondent should procure some thin tarred twine and birdlime. The twine should be stretched and crossed in irregular lines from 6ft. stakes and about 20ft. apart, from line to line across the vegetable quarters. Some light twigs should be well smeared with birdlime and placed suitably. If they adhere to the birds' feet when they fly off the birds will not soon return. Twine, so placed, at 50yds. asunder, will keep off crows and pigeons from fields. Fix twine 6ft. above ground level.

WAKELEY'S celebrated HOP MANURE (PATENTED.) THE MOST PERFECT FERTILIZER FOR GARDENS, GREENHOUSES, LAWNS, ETC.

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

BEWARE OF IMITATIONS.
Genuine Only in Our Marked Bags containing Guaranteed Analysis.

A BEAUTIFUL FREE BOOKLET giving full particulars and testimonials sent on receipt of postcard.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only **7/-** carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

Cash Prices (including bags): Small (about 1 bushel), **3/-**; Large (about 4 bushels), **7/-**; 5 Large, **33/9**; 10 Large, **65/-**; 20 Large, **120/-**.

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond.

CO-OPERATION

IN this number readers will find that considerable alterations have taken place in THE GARDEN. What these are can easily be seen on reading through the pages of this and following issues.

Gardening is becoming more and more popular every year. The reasons are difficult to determine ; they are partly economic and partly psychological, at any rate they are beside the point ; but what is interesting is that the essence of gardening is changing. In days gone by practical gardening was mostly in the hands of what Americans call " hired men," whether skilled or unskilled. The owner looked on, gave advice, sometimes hardly qualified, and admired the result, but that was all. Now a new race of gardeners is springing up, men and women who carry on a trade or a profession and still find time to work at and in their garden as a hobby and a recreation ; they are interested both in cause and effect. This is the case both in large and in small gardens, although the latter predominate.

Needless to say, we realise that post-war difficulties are strewn in the gardener's path ; we recognise the increase in the cost of labour and materials, the decreased spending power of the individual, and so on. But these difficulties, so liberally scattered, are not entirely economic ; there is a new kind of difficulty which is increasing every year, that of choice. As gardens tend to become smaller and more easily workable, so the number of varieties and species of plants seems to increase. There is a constant flow of new introductions from abroad, while native raised hybrids and varieties appear on the horizon or disappear from ken with bewildering rapidity. To us, it seems that this mass of material is the greatest puzzle with which the new gardener has to contend. He finds that it is impossible to grow even a tithe of all the good things, either mentioned in a horticultural journal or seen on the benches at the shows of the Royal Horticultural Society, so, in desperation, he chooses to specialise in one particular flower. In a way this is a pity, for the main foundation of our solid and deserved reputation as gardeners rests upon our old-fashioned mixed gardens, where could be found the well filled herbaceous border with its masses of lupins and hollyhocks and delphiniums and those oddly attractive corners of the kitchen garden filled with lavender or old sweet smelling roses. Then it was the result that counted. The new race of gardener, as interested in the growing of plants as in the result, points out with the greatest pride the rarest plants in his garden, whether in flower or not. Truly this is the age of the collector and specialist.

These remarks may appear to be a little outside the scope of the title of this article, co-operation, but they really are not, for they help to show that the difficulties which beset the gardener also affect the horticultural journal. It has to keep an exceedingly close watch on all things, large or small, which may be of interest to the gardener.

The very best service which a gardening paper can give to its readers can only be supplied if there is the very closest co-operation between them and the paper. The responsibility of the reader does not end when he has finished looking through the pages of the paper. Our correspondence columns exist for him and his fellow gardeners. One of the greatest joys of gardening is that it is not a close corporation. There are no trade secrets which have to be jealously guarded. If new methods of cultivation or new plants are found, information is willingly given for the use of the gardening world in general. It is as a vehicle for this information that our correspondence columns exist. If the information in our pages is incomplete, or either we or our contributors stumble, our correspondence pages will afford the remedy.

It is only by co-operation between paper and reader that the fullest advantage can be taken of gardening information, and we ask for, indeed shall welcome, this co-operation.

From time to time it will be seen that the by-paths of horticulture are also traversed. It is by such divergences from the straight highway of pure horticulture that we hope to be able to draw others into the world of gardens. From those who can now properly lay claim to the description of garden enthusiast we are bold enough to ask for sympathetic help on behalf of their less fortunate brethren. To be thrown down unaided into the mazes of modern horticultural technicalities is an even more awe-inspiring thought than the Biblical story of Daniel in the lion's den.

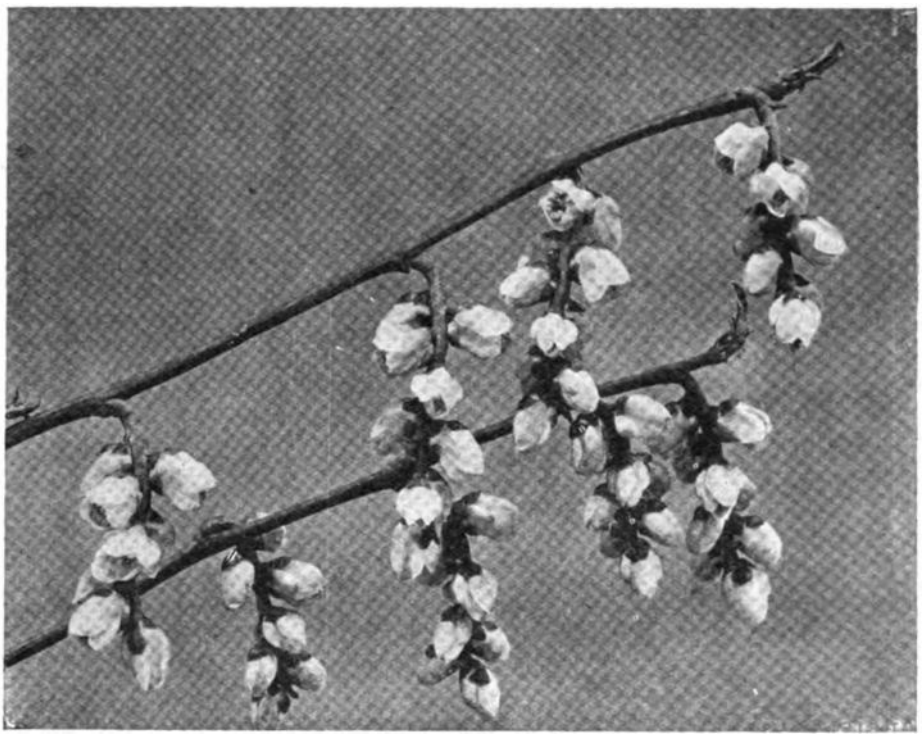
TREES AND SHRUBS

BY W. J. BEAN.

FLOWERING SHRUBS FOR A MODERATE-SIZED GARDEN.—I

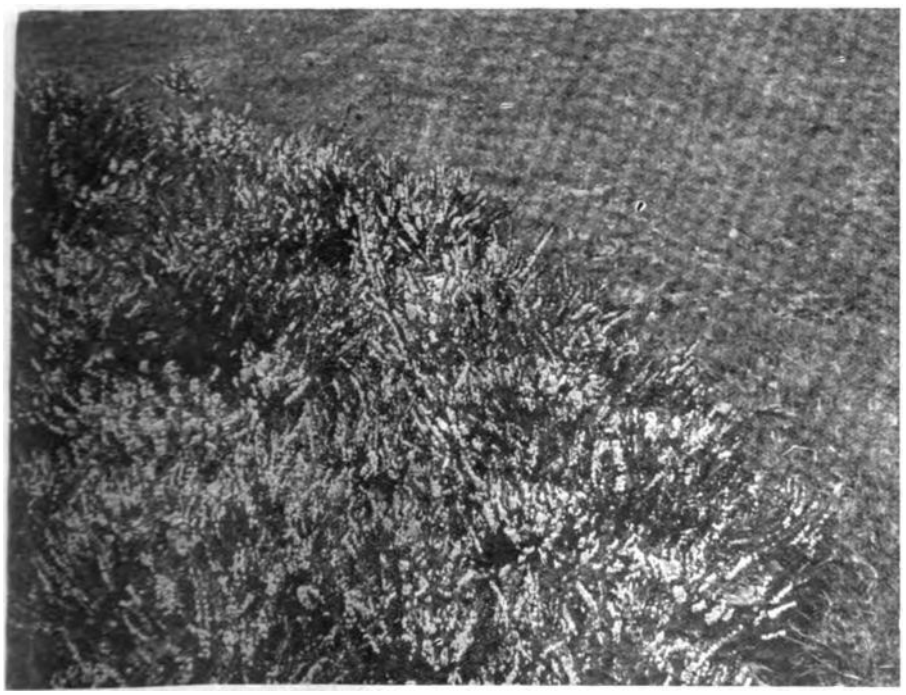
SO vastly has the number of really beautiful shrubs increased in the present century, both by introductions from other countries and by hybridisation and selection at home, that only the largest gardens can hope to find room for more than a selection of them. For small gardens, of course, the difficulty of providing room is proportionately increased; yet, as one goes about the country, it is very evident that the faculty of selection by the owners of such gardens is exercised to an insufficient extent. A really good shrub takes up no more space—in fact usually less—than one of poor or mediocre quality, yet even to-day one may see such things as laurels, privets, aucubas and the common pontic rhododendron occupying excellent situations that really good things might fill. Through change of taste and considerations of expense, glasshouse gardening has declined very much in recent years; it has, therefore become all the more important that such space as is available in the open air should be put to the best use possible. In a garden where, say, an acre of ground can be devoted to trees and shrubs and lawns, a very excellent company can be entertained, providing beauty, variety and interest for a good many months of the year. Since the war, plants, like most other things, cost more than they did; but, once the initial expense has been met, there is no form of gardening that will provide greater pleasure at such a low expenditure, either of money or time, as the cultivation of shrubs.



THE PENDENT RACEMES OF STACHYURUS CHINENSIS.
This fine shrub was introduced into cultivation by E. H. Wilson.

In a garden of the size I have in mind, a few trees are necessary to provide shade, shelter and background, but for my present purpose I must assume they already exist. What I have to do now is to offer a selection of shrubs which, as a friend of mine expresses it, will return the best dividend on the labour and cost entailed in procuring and growing them. Most shrubs when once established need very little attention. The ground beneath them should be kept loose, and free from grass and weeds; an occasional mulching is often advantageous; a little attention in the matter of pruning may be needed, chiefly the removal of dead and weakly branches, or—if one's taste runs that way—to induce a shapely growth. Some kinds, such as Berberis stenophylla, the laurustinus, or the loose-habited rhododendrons, the branches of which ultimately reach and rest on the ground, will, when that stage has been reached, need no attention at all unless they overstep their bounds.

For those who contemplate planting a new garden of moderate size or replenishing one already existing, I consider 100 to 150 different kinds of shrubs as constituting at least a good commencement and suggest about that number for the purpose, having due consideration for variety and for beauty at different seasons of the year. I will not claim they are invariably the best, opinions as to quality are too diverse for that, but they shall at any rate be good ones. By reference to current catalogues of nurserymen I have ascertained that all or almost all are obtainable in the trade. I must premise that statements as to hardiness, rates of growth and time of flowering are intended to apply to the London district.



ERICA DARLEYENSIS.
One of the finest of the early heaths.

Digitized by Google

EARLY FLOWERING SHRUBS.

Commencing with those that flower with the opening of the New Year, there is one shrub which stands out as indispensable and that is the Chinese witch hazel, Hamamelis mollis. This year it has been later than usual, but as a rule we may expect it near London to be fully open on New Year's Day. Not only are its flowers larger than, and as richly yellow as those of any other witch hazel, but they are also strongly and sweetly perfumed. On a mild day in January the fragrance extends for many yards around the bush. One other hamamelis should be grown, H. arborea, which flowers a few weeks later. It is really a very good form of H. japonica and although the name would imply a tree-like habit, it will take many years to grow over twelve feet high.

AMONG THE SHOWIEST OF ALL THE MAGNOLIAS. M. STELLATA.

Two heaths, Erica carnea and E. darleyensis, commence to flower in January and February, the former is about one foot high the latter twice as tall. Their rich rosy-red blossoms provide a colour not very common in these early weeks of the year when most flowers in the open air are white, yellow or blue. Unlike most of the heath family these two thrive where there is lime in the soil. So much cannot be said for Rhododendron mucronulatum, a relative of the old R. dauricum, but much superior to it as a garden plant. It is worth growing for its great beauty at a dull season, but it has to be said that it blossoms very much on sufferance, inasmuch as a few degrees of frost destroy its beauty for the time being, although a second or even a third batch will sometimes follow. In this respect it is far behind the witch hazels and heaths mentioned, which bear moderate frost with impunity. It should be planted where there is shade from the morning sun and if possible some overhead shelter. Perhaps it is a debatable matter whether it should be included in this selection, but few people seeing it in its full glory of purple on a dull February day for the first time would turn down their thumbs.

DAPHNES.—Daphne Mezereum, with its stiff branches thickly set with reddish purple flowers opening in February or March is always a joy for its fragrance alone. Although wild or naturalised in a few places in Britain, it is not always an easy shrub to cultivate and possibly, like other daphnes, not naturally a long-lived one. I believe it likes cool, moist conditions and is sometimes weakened by excessive seed-bearing. This, however, renders its perpetuation easy. In my experience, D. neapolitana, often called D. Fioniana, is the most dependable in this genus, an evergreen bush 2ft. or 3ft. high, with terminal clusters of rosy purple fragrant blossom, opening from March to May. D. Cneorum does not flower till May and seems too short-lived to figure in this list, but it is a dwarf evergreen of wonderful beauty. None of the daphnes objects to lime, most of them apparently prefer it.

MAGNOLIAS.—The opening of the flowers on these early shrubs is dependent, of course, on the character of the weather, and the advent of a "skating" January and February will postpone it for several weeks, but Magnolia stellata may be relied on to blossom during the last week of March, if not before. Such a wealth of pure white flowers does it bear, so unfailingly is it set of bloom when the shrub is once established, that it cannot be omitted here, although it is unusual for it to escape all injury from frost. Still, a first crop spoiled is often followed by a second. An attractive combination of blue and white can be made by underplanting it with grape hyacinths. Having introduced magnolias, the best shrubby sorts may be here discussed. M. Soulangiana flowers in April and keeps on more or less through that month and May and, if not the most beautiful of the magnolias, is one of the most reliable, flowering freely and unfailingly. It is a hybrid bearing fertile seeds from which many varying forms have been raised. Its petals are always more or less suffused with purple on the outside, but in the var. superba this almost disappears. In M. Lennei, also a hybrid of the Soulangiana group, the flowers are almost entirely dark rose-purple outside and the petals are broader and larger; they open some weeks later. A very fine variety also is M. rustica rubra with more red and less purple in its colouring. M. parviflora and M. Wilsonii, two allied species (the latter I fear not easily obtainable yet), do not flower till June; their flowers are white with a conspicuous central ring of rosy-crimson stamens. For its late-flowering and fine foliage, glaucous underneath, I would also grow M. Thompsoniana, a hybrid from M. glauca, with exquisitely scented white flowers larger than those of M. glauca itself, to which species I think M. Thompsoniana is to be preferred, although it, too, is a very charming shrub.

Among the yellow-flowered shrubs of March the first place must be given to the forsythias, easily grown, very hardy plants of which three species and several varieties are known. The best of all forsythias I consider to be F. intermedia var. spectabilis. F. intermedia itself is a hybrid between FF. suspensa and viridissima, and this variety, distinguished by richer yellow and extraordinarily abundant flowers, is a seedling from it.

HEATHS.—An indispensable spring-flowering shrub is Erica mediterranea, which is really a tall-growing form of the E. carnea already recommended. In March, its first flowers commence to open and the bush remains in beauty and fragrance until the warm days of May cause them to fade. The flowers are rich rosy red. There is a variety with white flowers (alba), not so robust as the type, which associates admirably with it. There are other beautiful heaths of tall growth, such as Ericas australis, arborea, lusitanica and Veitchii, but they are sufficiently unreliable as to hardiness in the London area to be scarcely admissible into the present selection. To finish with the true ericas, the Cornish species, the dwarf E. vagans, may be mentioned for flowering from July to October, a good form with deeper rosy-red flowers is known as rubra. Dabœcia polifolia, St. Dabeoc's heath, is a very lovely evergreen growing 2ft. high with small glossy dark green leaves and erect racemes of glowing purple, pitcher-shaped flowers which commence to open in June and keep on till October. A pure white variety should also be grown.

A shrub of great beauty, but much neglected is Stachyurus , a native of Japan. It blossoms sometimes in February,

Digitized by Google

sometimes in March, the pale yellow flowers, each about ¼in. wide, being produced on stiffly pendulous racemes some three inches long. The plant itself is deciduous, of thin graceful spreading habit and grows 6ft. or more high. When the arching branches are thickly set with racemes, as they almost invariably are every spring, no one can deny it a place among the *élite*. Wilson introduced a very closely related species from China, S. chinensis. So much are they alike and so equal in beauty, that only one of them need be grown; it does not matter which.

RARE TREES AND SHRUBS

EMMENOPTERYS HENRYI.

To get a tree or shrub with flowers equal in beauty to those of the well known Luculia gratissima and hardy enough to grow in the open air without protection seems almost too much to hope for. Yet that is what this new Chinese tree promises to be. It belongs to the same Natural Order of plants as the luculia—the Rubiaceæ—and has somewhat similar textured opposite leaves of oval outline and up to 8ins. in length by 4ins. in width, dark dull green and smooth above, pale and with down on the midrib and veins beneath. The flowers are borne at the end of the shoot in flattish panicles, as much as 10ins. wide and 6ins. to 8ins. high. Each flower is 1in. wide, funnel-shaped at the base, spreading at the top into five rounded lobes; they are white and downy on both surfaces, especially inside. But besides the beauty of the corolla, the inflorescence has an additional attraction. The calyx is normally small and inconspicuous, but in a certain proportion of the flowers one calyx-lobe becomes extraordinarily enlarged and develops into a large, white, more or less oval bract, the largest of them as much as 2ins. long by 1½ins. wide. They are somewhat similar to what one sees in Schizophragma.

The emmenopterys is a native of Yunnan, Szechuen and Hupeh, and it was introduced from the last-named province by Wilson to the Coombe Wood Nursery. I do not think many were raised, but in 1913 I obtained one for Kew, where it has grown outside ever since and has never suffered in the least from cold. It is now 8ft. or 9ft. high. Mr. Wilson, in his notes on this tree, says he found it in woodlands growing 30ft. to 80ft. high, with a stout trunk. He describes it as one of the most strikingly beautiful trees of the Chinese forests, and in July, when in full bloom, making conspicuous splashes of white there. It is rather slow in growth at Kew, and I expect would succeed better in the south and west. Still, as already stated, it has not yet shown any sign of tenderness. It is deciduous and can be propagated quite readily by means of cuttings made of late summer growth. No flowers have yet been borne on cultivated plants, and the particulars given above have been obtained from preserved specimens collected in its native woodlands. Mr. Wilson says the remarkable bracts do not fade with the flower, but remain and turn pink as the fruit ripens.

PYRUS ELEYI.

Mr. Charles Eley of East Bergholt in Suffolk raised this crab from Pyrus Niedzwetzkyana crossed with the pollen of Pyrus spectabilis. Judging by its parents, it will probably become a tree 30ft. high. Its young shoots are downy, and both they and the leaves are reddish purple like those of the mother plant, but of a brighter and not so dark a hue. The leaves are ovate with a short, sharply pointed apex, rounded or wedge-shaped at the base, finely toothed, 2ins. to 4ins. long, 1in. to 2½ins. wide, downy beneath, especially on the dark purple midrib and veins. The flowers come in apple-like clusters and are of apple blossom shape, each blossom being 1½ins. wide and of a rich vinous red. The fruits are rich purplish red, conical, 1in. long, ⅝in. wide at the base, each on a slender stalk 1½ins. long.

From the time the flowers open in April until the fall of the leaf in autumn this new crab is beautiful. It is very attractive when in bloom, but its charm is greatest when its thickly clustered pendulous fruits have acquired their rich colour; but even during summer, when the flowers are past and the fruits as yet undeveloped, the persistent brightness of the leaves and shoots gives it a high place among ornamental foliaged trees. In combining the high and unique colouring of Pyrus Niedzwetzkyana with the profuse blossoming of P. spectabilis, Mr. Eley has achieved a great success. The Royal Horticultural Society has recognised its value by the award of a first-class certificate.

PYRUS (MALUS) ARNOLDIANA.

This beautiful crab originated about 1905 in the Arnold Arboretum, where it first appeared among some seedlings of Pyrus floribunda. Professor Sargent suggests that it is probably a hybrid between that crab (itself a hybrid) and one of the larger-flowered hybrids of Pyrus baccata. A plant sent to Kew a few years ago has bloomed for several years past and proves to be a very charming addition to its group. In habit it is extremely graceful, producing long arching or semi-pendulous branches which, when young, are redder than those of P. floribunda. The foliage is similar, although the leaves are perhaps of somewhat larger average size. The flowers are more than half as large again, being about 1½ins. in width. In the bud state the petals are of a ruby red, paling with age to deep rose outside and pale rose inside. As with P. floribunda, the beauty of the tree is greatest when half the flowers are still in the bud state, but compared with those of the older tree they are larger and much more richly coloured. The flower-stalks are slender, reddish and from 1½ins. to 2ins. long, the lobes of the calyx awl-shaped and ¼in. long. Both flowerstalks and calyx are nearly smooth, while in P. floribunda they are downy. This crab flowers in April and it seems safe to prophesy will become a popular and well known tree in future years.

THE FLOWERS OF PYRUS ELEYI, A RICH VINOUS RED.

THE ROCK GARDEN at BROCKHURST

THE RESIDENCE OF MR. FREDERICK J. HANBURY, F.L.S.

WITH NOTES BY THE OWNER.

BY the special desire of the late secretary, Mr. Wilks, I gave an illustrated lecture before the Royal Horticultural Society in October, 1916, on the rock garden that I had just made at Brockhurst, East Grinstead. A fairly full *résumé* of this lecture was printed in the Journal of the Royal Horticultural Society, Vol. XLII, Parts II and III, and about a dozen out of the hundred odd slides then shown were reproduced as pictures in this report. Great changes have occurred in the intervening seven years, principally through the vigorous growth of the plants, many of which were scarcely visible among the great masses of bare rock to be seen in the earlier pictures. The illustrations to this article will show at a glance that much of the bareness visible in the earlier pictures has disappeared; and here may I put in a word about rock gardens being allowed to fill up of their own accord. It is useless to expect a rock garden to appear fully clothed within the first year or two of its inception; on the other hand it is not a wise policy to plant so thickly to begin with that a year or two's growth will transform a well planned rock garden into a tangled mass, where many rare plants may be choked out of existence. It is a good plan in an old well filled rock garden to keep a corner for experimenting with plants. If they prove their worth they can be incorporated in the general garden, but it is a mistake to remove a fine plant of A because somebody has told you in a vague fashion that B is far superior. A rock garden should be viewed as much as a whole as for individual plants it may contain.

The following short particulars concerning the natural features of our garden may not be out of place. Brockhurst is 400ft. above sea level and is situated between East Grinstead and Forest Row in Sussex, and the naturally undulating ground slopes to the south-west. The solid rock which is found a short distance below the surface is geologically known as Lower Tunbridge Wells sandstone. The site of the rock garden is a rounded hill with a steep escarpment towards the north-west, and on it our cows grazed for two years before we accidentally discovered a fine mass of solid rock, some 30ft. thick, while digging holes for planting a belt of rhododendrons. We began on a small scale with the excavated rock, intending to make a rock garden at the base of the hill. As this grew bigger and the excavation in the hill grew larger, we were gradually led on to make our present garden. Details concerning this work and of the formation of the moraine, in making which I had the aid and advice of Mr. E. A. Bowles and of the late Reginald Farrer, will be found in the paper to which reference has been made. The work of construction occupied about four years. Besides having the rock *in situ*, we are also favoured with the presence of several never-failing springs which provide a plentiful supply of water.

A GENERAL VIEW FROM THE TOP OF THE MORAINE LOOKING SOUTH.
This is where many rare British plants are grown.

The average temperature at Brockhurst is about 2° cooler in summer and 2° warmer in winter than that of Greenwich.

The rock garden is best entered at the lower end where the mounds are of moderate height and separated by undulating paths. This portion provides suitable homes for a large number of the smaller plants.

The following may be mentioned among others: Sempervivum soboliferum, which was given to me fifty years ago by the elder Fries while on a visit to Upsala. It was taken from a clump on Linnæus' garden wall, where it was known to have been planted by Linnæus himself, and it thus supplies a living link with the great botanist. It quickly multiplies itself by forming small bulbils round each rosette, which bulbils roll off and form plants. Then there are fine clumps of two or three species of Iris (Sparaxis) planted on a low bank which throw their

IN THE DEFILE.

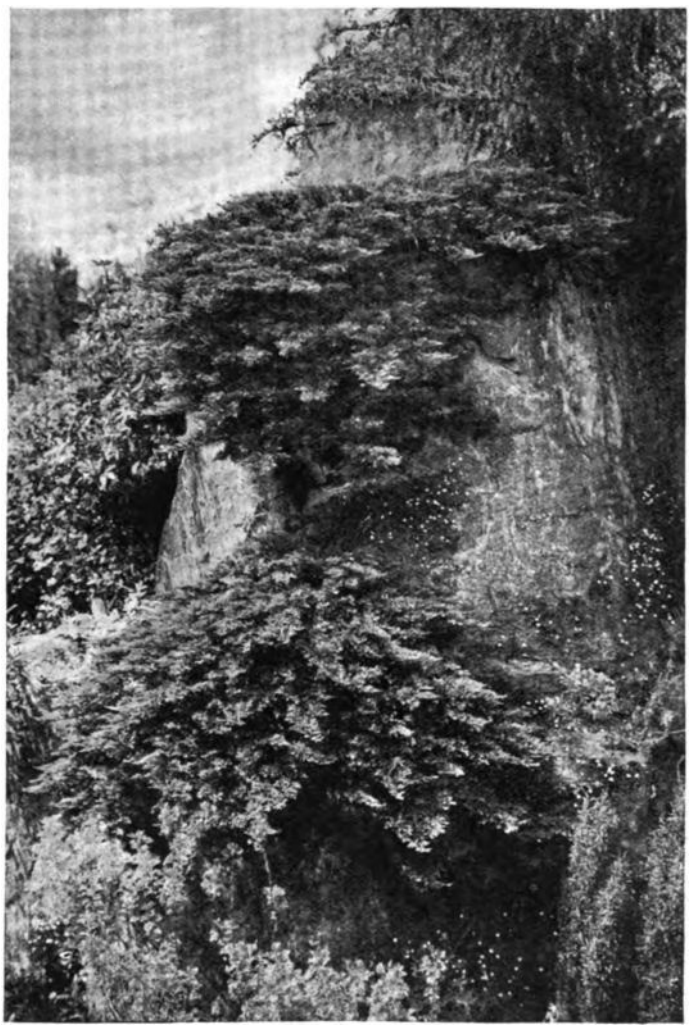
THE DEEP CHASM.
It is here where many rare British ferns flourish.

graceful arching stems right over a small path below and produce a charming effect in August, when so many of the surrounding plants have passed out of flower.

Many species and varieties of the mossy saxifrages grow here, and other plants worthy of enumeration are: Tulipa sylvestris, our native tulip; Urospermum Dalechampii, a fine pale yellow composite the ligules of which are fringed with black, so that, when expanding, the flower appears to have a large black eye in the middle, which disappears when fully out. There are many helianthemums, androsaces, primulas, violas, geraniums, sundry labiates, cistuses, azaleas, heaths, dwarf irises and a fine clump of Watsonia Ardernei which has stood our winters well and has greatly increased and usually flowers freely. Potentilla rupestris, which was collected on Craig Breiddin by the late Bishop Walsham How, sows itself about very freely. Its tall



JUNIPER POINT.
This illustration shows the growing power of the fresh garden soil. These junipers were planted ten years ago.

habit and pure white flowers make it an attractive plant. By the first pool is a fine plant of our rare Mulgedium alpinum from Forfarshire. Its deep blue flowers are a pleasing contrast to the pale washy flowers of other mulgediums which are frequently confounded with it. It does not run as do others, and is not the easiest of plants to keep in good condition. There are also a few celmisias and a good plant of Olearia insignis.

There is a central, though winding, path nearly 200yds. long, which leads eventually to the great chasm. On either side of this there are steps at intervals leading to paths which run at a higher level along the tops of the banks. About half way along the central path on the right is a sunken portion that is kept wet and which accommodates many marsh plants. This open boggy ground makes a welcome break in the general character of the rocky scene, and provides a wide open space.

Digitized by Google

In it grow many rare marsh plants, including a large patch of Carex Buxbaumii, found only on the shores of Lough Neagh in Ulster, C. aquatilis from Perthshire, and sundry mints, roscoeas, docks, bog myrtle, Bartsia viscosa, orchises, horsetails, etc. On the banks around this open space are several of our most interesting heaths and their hybrids. Among these I may especially mention the very attractive Erica vagans var. St Keverne, E. vagans alba and E. Williamsii, which is a cross between E. vagans and E. Tetralix. All these were discovered by Mr. P. D. Williams on or near to his estate at St. Keverne, on the Lizard peninsula. Only a single plant was found of the latter, and from it all the plants in existence have been propagated. I believe it is the only known British hybrid of E. vagans. E. Watsonii, a cross between E. Tetralix and E. ciliaris, also grows by the edge of the bog alongside E. Tetralix, one of its parents. This plant has occurred in Cornwall, but I found mine near Poole Harbour in Dorsetshire. The handsome E. mediterranea and E. lusitanica also grow hard by, as well as E. Mackayi from Connemara and sundry varieties of E. carnea and the large-flowered Irish heath, Dabœcia (Menziesia) polifolia. A good bush of our only British cotoneaster, viz., C. vulgaris, from the Great Orme's Head, and a patch of our rare Astragalus hypoglottis from the Forfarshire coast, are also planted here.

AN ENTRANCE TO THE ROCK GARDEN.
So many blind corners add an element of surprise.

Proceeding along the path, which is here widened out and has miniature bogs on either side at the base of the banks, we reach, on the left, steps which ascend to a path through the moraine. To the right the central walk continues through a defile cut through the solid rock and ends eventually in the great chasm, whence the bulk of the stone was quarried. In the defile one of our illustrations shows the entrance to a long, winding and branched cave which was excavated when we wanted additional stone, but which now forms an attractive feature of the scheme. The first illustration is taken from the upper part of the moraine, looking back, and shows several of the features to which reference has just been made. In the main chasm, which is seen from different points in the third and sixth pictures, is a deep still pool with a dripping well at one end. Escape on either side from this cul-de-sac is provided by long flights of stone steps. Those on the left, the upper portion of which is shown in the last illustration, lead eventually to a walk among the highest rocks, whence there is a fine view of Ashdown Forest and distant hills, with the most rugged portion of the rock garden lying immediately below and supplying an effective foreground to the picture. The natural vents and crevices in the rocks accommodate a large number of plants, such as encrusted saxifrages, the tall white saxifrages, many sedums and sempervivums, pinks, the rarer species of small ferns such as Asplenium viride, A. lanceolatum, A. septentrionale and others, but the generality of the plants grow in the ordinary pockets that were made during the work of construction.

Throughout the rock garden there are many flowering shrubs and trees, especially is this the case as regards its outer banks. These alleviate the appearance of monotony and flatness. In some parts they are already tending to grow too large and thus to hide pleasing rock effects and to smother or overshadow the smaller plants in their vicinity. Minor alterations to overcome these drawbacks are frequently necessary. It is impossible in the scope of a short article to give a long list of the plants grown. There are several thousand species and varieties. It may be well, however, to point out that our object has been not only to collect and provide suitable and natural positions for the larger proportion of alpine plants and small flowering shrubs that are commonly grown, but also to make the garden interesting from a botanical point of view. In this connection we have introduced native plants that are intrinsically beautiful, such as Ranunculus Lingua, Primula elatior and its natural hybrids with both primrose and cowslip, Vicia sylvatica, of which the strong climbing habit and beautiful lilac-coloured flowers make it a desirable plant for large rock, or rough woodland, our native gentians, Myosotis sylvatica which will grow in dry places and sows itself about, our coast and mountain violets, such as Viola Curtisii and V. lutea, some of our rarer St. John's worts, such as Hypericum undulatum and H. linarifolium. But this list could be extended indefinitely. To botanists

the willows, rare sedges and grasses, the mints, geraniums, chickweeds, pinks, clovers, hawkweeds and many rare ferns and horsetails, make a strong appeal.

The attempt to combine all the above features, as far as possible under natural conditions, is perhaps the main characteristic of the rock garden at Brockhurst. The scheme was designed by ourselves at home, largely during the progress of construction and here I must acknowledge the great debt I owe to my head-gardener, Thomas Matthews, for the very important share that he took in the work.

THE GARDEN OF THE QUEEN'S DOLLS' HOUSE

BY SIR LAWRENCE WEAVER.

[The wonderful model palace known as the Queen's Dolls' House, which will be exhibited in the Palace of Arts at Wembley, is the outcome of an idea originally expressed by Her Majesty to Sir Edwin Lutyens, the architect of the "building." This was, in effect, to make a model of what a great house of 1924 would be like if built on the lavish scale in which things used to be done in the seventeenth and eighteenth centuries; so that not only future ages would find in it a document for the early twentieth century, but we ourselves could see what might be done "if things was diff'rent."

All the finest artists and craftsmen have contributed to the perfection of this little memorial to our age, as well as most of the leading commercial houses who minister to our domestic needs. Electric light and lift, frescoed ceilings and walls, splendid furniture, books, rugs, linen—these are all provided to scale, and in the vaults we find dozens of wine, cases of beer, and every kind of stores.

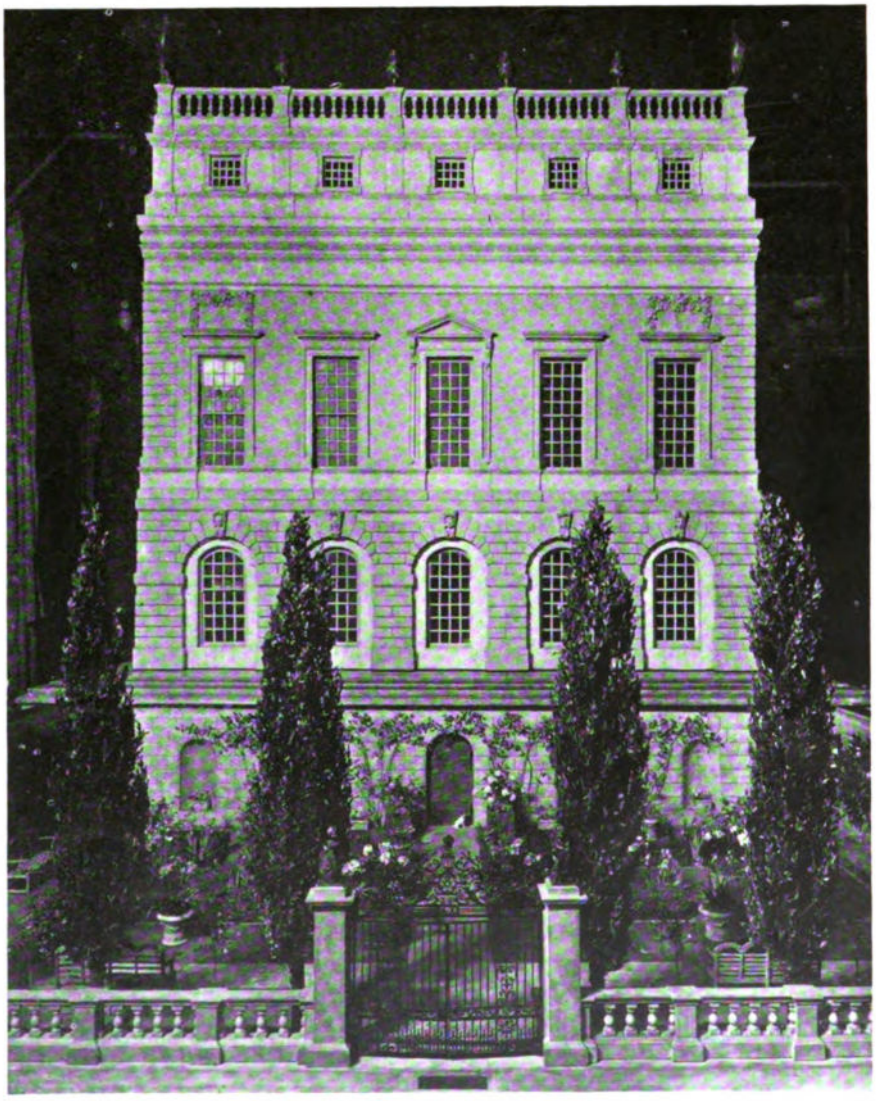
Here we give an account of the garden, which is so made that it can fold up and slide under the house itself, like the flap of a writing desk.—ED.]

IT might be supposed that whatever perfection could be achieved in the building of a palace in miniature—to the scale of one inch to a foot—whatever miracles of convincing tininess might be performed by the makers of motor cars, a grand piano, a gramophone—the problem of a garden in miniature would defeat its designer.

But Sir Edwin Lutyens, under whose brilliant direction hundreds of artists have given of their best to create a unique thing—and the word unique is used in its strictest sense—was not defeated.

With the aid of Miss Beatrice Hindley's deftness of workmanship and faithful study of botanical forms, the Queen's Dolls' House has been furnished with a garden of exquisite form and colour.

The first problem was its placing. The Dolls' House is 8ft. 6ins. long and 4ft. 10½ins. broad, and stands on a base about a foot larger each way, so in size as well as in magnificence of detail it is a Queen among Dolls' Houses. Had a garden been designed to surround the house, or even to extend along one front of it, the whole scheme would have been unmanageable.



THE HANGING GARDEN.
Enclosed by cypress trees, with paved walks, and a wonderful variety of flowers.

With typical inventiveness, Sir Edwin Lutyens got over the difficulty. In the base on which the house stands are two drawers about eleven inches deep, with falling front flaps. One of them can be extended on double runners and contains the garden. But that, the imaginative would-be visitor may say, would leave no room for anything in the way of walls or gates or trees higher than 11ft., if full scale. Not at all. The drawer front is invisibly hinged at the back line of the stone paving where it adjoins the grass, and the iron gates and balustrade and trees over 24ft. (if full scale) high are fixed to the front, so that when the front is lowered, they come into their proper places and the garden is a complete and imposing whole. So adroitly has the garden itself been devised, that when the drawer front is

Digitized by Google

raised again the trees fold away neatly.

Students of Sir Edwin's achievements as a garden designer will not need to be told that he has devised the Queen's garden on formal lines, befitting the early eighteenth century character of the house, which is a token of homage to Sir Christopher Wren. The back wall of the garden is furnished with four round-headed niches flanking a central doorway, all five openings related to the treatment of the dining-room windows on the ground floor, which comes above the garden. The grass is of green velvet and a motor mowing machine stands by, so that the tradition of English lawns may be maintained with faithfulness. On either side of the paved middle path are two sets of four beds with a stout hedge of box on their outer edges and a smaller edging within. The flowers are various and rich in their kinds. Blue and purple iris, standard roses, lilies and sweet peas, poppies and marigolds, mallows and gentians—these fill the beds. There is agapanthus in terra-cotta vases, hydrangea and rhododendron in wooden tubs, and Magnolia grandiflora graces the stone walls. Pale climbing roses bedeck the niches.

All these plants are of repoussé metal most delicately formed by Miss Beatrice Hindley after long study at Kew of plant and flower forms, and enamelled in their proper colours.

THE GARDEN DOOR TO THE PALACE.
There are rhododendrons in tubs and agapanthus in vases.

The tree trunks are of solid metal and their branches of real twigs of dwarf growth most cunningly chosen. Even the animal denizens of a garden have not been forgotten. It is to be hoped that the miniature Majesty who will revel in this pleasaunce will not be so keen a horticulturist as to destroy the snails which may be seen, or make war upon the butterflies that have settled on the flowers, in fear lest they later bring a host of caterpillars. The little Princes of Royal Blood must be watched by their suite, lest they pillage the eggs which mother thrush has laid in her nest.

It is all very astonishing as a *tour de force* of design and workmanship, but it is something more. Queen Mary is a lover of gardens not only for their own sake, but as appanages of homes. So this Dolls' House and its garden are an expression of affectionate loyalty from a great band of artists and craftsmen to a Royal Lady for whom the domestic arts are handmaids of beauty and comfort in the homes of the Empire, where Her Majesty holds her place secure in her peoples' hearts.

And it is characteristic of the Queen that she is going to defer the delight of possession until her Dolls' House has done a great work for those who suffer. It will be exhibited in a specially built gallery of the Palace of Arts at the British Empire Exhibition this year and the whole of the gate money will be at the disposal of Her Majesty for those charitable causes to which she devotes so large a part of her energies. It is certain that many thousands of people not only of this country but also from the colonies will visit the Dolls' House at the British Empire Exhibition.

PAVED PATHS WITH BOX EDGING.

PRUNING NEGLECTED FRUIT TREES

BY N. H. GRUBB AND A. W. WITT.

THE pruning required by a neglected fruit tree depends on the kind of tree, its condition, and the size and shape of tree desired. It is not possible to lay down rules of universal application. Successful pruning requires judgment and observation, and the treatment of each tree as a separate individual. A method which will restore an apple or pear tree to good condition may result in the disease or premature death of a plum or cherry tree. Again, the treatment required by a neglected standard or bush tree will clearly be different from that needed by an overgrown espalier or cordon tree. And further, although trees which have been left unpruned for several years are usually overgrown, tall, and out of shape, lack of pruning sometimes results in a weak or diseased condition. Clearly the condition of the tree must be considered in deciding on the proper treatment.

STANDARD AND BUSH TREES.

If the trees are neither too wide-spreading nor too tall, and if they are healthy, a mere thinning of the head will be enough. Here the object is to open the head, to let sunlight and air penetrate, and to prevent the death, through shading, of the spurs on the interior branches. As a rule, it is better to thin out the weaker and crossing branches piecemeal than to cut out the whole of large branches.

With apples and pears more drastic treatment may often be an advantage. If the trees are too tall or wide-spreading, or if the branches have lost most of their spurs, or become cankered, the trees may often be restored to good condition by "heading back"—*i.e.*, the cutting back of the main branches to a considerable extent, in extreme cases even to within a foot or two of the main trunk. It is best, where possible, to cut each branch immediately above a small side branch or spur, from which renewed growth will be formed; if this is impossible, one may rely on the formation of shoots from adventitious buds, of which the best placed can be chosen to form the new branch, and those not wanted to form spurs cut clean away. With trees of any considerable size, it is always best to spread this process over two years, instead of cutting all the branches the first winter.

Where the variety is unsuitable or subject to disease, the opportunity may be taken to regraft with another variety. Some gardeners even regraft with the same variety, instead of relying on growths from adventitious buds, which may be badly placed.

Where the "heading back" is intended primarily to reduce the size of the tree, it is usually best to root prune the tree moderately, either at once, or a year later. The method is described below.

With plums, damsons, and cherries, the risk of disease, particularly "silver-leaf," makes it usually inadvisable to head back severely, even where trees are too large. Where silver-leaf is known to be rare, as in some parts of the North and Scotland, plum trees may be treated as described above for apples and pears; but even there it is wise to paint the larger wounds with a protective covering, *e.g.*, gas tar. Where silver-leaf is prevalent, as in most parts of England, it is better to put up with tall, awkward trees, unless one is prepared to risk their loss. Beyond cutting out dead wood, a moderate thinning of the head and the shortening of long, straggling branches, it is inadvisable to do much to standard and bush plums and cherries.

PYRAMIDS.

Neglected pyramids are usually so much out of shape that a severe heading back is needed to restore them to their proper form. Unless a shapely pyramid is particularly desired, it is often better to convert such trees into half-standard or tall bush trees; this can usually be done by cutting out the central branch or leader at from three to five feet from the ground. At the same time the very low branches can usually be cut away without loss of fruit.

ESPALIERS.

Neglected espaliers usually become very much overgrown; the fruiting spurs, especially on the upper tier of horizontal branches, tend to grow up into branches on their own account, and may be even six or eight feet high. The weaker of these tall growths may be shortened, if necessary to a fruit bud, not far above the original branch; the stronger growths are better cut clean out, flush with the branch from which they spring. In extreme cases it may be necessary to cut the top tier of horizontal branches back to a point near the central stem, with a view to training in new branches. Where this is done it is a good plan to tie up the lower branches temporarily to an angle of, say, 45°, in order to strengthen their spurs.

When such trees have been neglected for more than two years, their complete restoration is seldom possible in the first season; it is sometimes necessary to spread it over three years. In any case, it must usually be accompanied or followed by root pruning.

A. ESPALIER PLUM TREE NEGLECTED FOR [illegible] YEARS.
To left of illustration, untouched; to right, first [illegible] done.

CORDONS.

Overgrown and neglected cordons usually resemble badly shaped pyramid trees; the spurs have grown out to a great length, and the leader will generally have reached a much greater height than is at all desirable. To restore such trees to cordon shape drastic treatment is necessary, similar to that recommended for espaliers. The long

Digitized by Google

C. SAME TREE AS B., HALF OF TREE (TO RIGHT) PRUNED AND TIED IN.

growths should be shortened, if possible to live buds within, say, six or eight inches of the main stem; and the main stem itself will often need shortening by several feet. Here again the process is best spread over two years, and root pruning will be essential for success.

WALL TREES.

Horizontal-trained apple and pear trees usually require treatment similar to that recommended for espaliers.

Neglected fan-trained plum and sweet cherry trees will usually have made strong wood growth from the upper branches; on the lower part the spurs will mostly be long and far from the wall. These lower spurs will require shortening; but this should be done gradually, one third, perhaps, of the spurs being shortened to within two or three inches of the branch the first winter. The remainder may be shortened in the following winter, or preferably later, as those first shortened come into fruiting.

The upper part of the tree will need more drastic treatment. The aim should be to replace gradually the over-vigorous and bare branches by training in any available shoots of one or two years' growth. If no such shoots are available, they can be produced by cutting hard back one or more branches on each side of the tree. If one or two of the shoots thus produced grow much more strongly than the others, as often happens, they may either be temporarily tied down horizontally, or may be shortened in the summer, as soon as it is clear they are taking the lead, and the resulting secondary growths tied in. The aim is to secure well balanced growths of moderate vigour.

Peach and Morello cherry trees require somewhat different treatment, since they fruit chiefly on shoots of the previous year's growth. The aim here should be to furnish the whole of the wall space with young fruitful wood.

Neglected Morello cherry trees have most of the fruiting wood on the tips of the branches; it is often too weak to fruit well, and there is usually much bare wood in the middle of the tree. Of the shoots standing away from the wall, those on the upper half of the tree should be cut clean out; on the lower half of the tree some will be too vigorous to be tied in, and should also be cut clean away; others may be tied in to take the place of some of the old bare branches. Some of the smaller branches over the whole tree should be shortened to within an inch or so of their base, to induce fresh growths for training in.

Neglected peaches and nectarines generally have very little new growth towards the ends of the branches, the fruiting wood consisting mainly of long spurs. Towards the centre of the tree there will usually be strong growths standing away from the wall; the less vigorous of these may be trained in, while the stronger are cut clean away. As with Morellos, some smaller branches and spurs should be shortened to produce new fruiting wood. If the spurs are very numerous, they should be thinned out.

ROOT PRUNING.

Wherever apple, pear and plum trees are too vigorous, or require drastic pruning to reduce their size, root pruning is advisable. The process involves cutting some of the roots at a distance from the trunk varying with the size of the tree, from, say, 15ins. for cordons up to 4ft. for very large trees. It is seldom advisable to cut the roots all the way round the tree in one winter; it is better to cut half round the tree one winter, and the other half the next. Care should be taken to get well under the tree from the bottom of the trench, in order to cut possible "tap" roots. With most soils it is well to ram the soil as the trench is refilled. October is considered the best month for the operation, but it may be done at any time during the dormant season.

CORRESPONDENCE

THE QUESTION OF THE INBREEDING OF RHODODENDRONS.

IN the Journal of the Horticultural Society for 1850, Messrs. Standish and Noble, formerly of Sunningdale, contribute a chapter on the history of hybrid rhododendrons. This is quoted at length on pages 28 and 29 of Mr. Millais' great work on "Rhododendrons, 1917"; he says that the firm in question was particularly active and successful. The chapter states *inter alia*, "We find that analogous to what is observed in the animal kingdom, the wider the cross the more healthy the progeny, and that breeding in and in produces weak and deteriorated constitutions. We have a remarkable instance of this in a batch of hybrids raised from R. caucasicum album (that being a hybrid) fertilised with its own pollen. The plants are extremely dwarf, with variegated foliage. So dwarf are they that many of them bore 8 or 10 flower buds when only 4 to 6 inches high and 4 years old. Flowers produced by these dwarfs were again fertilised by their own pollen and, although seeds were produced and these germinated, the plants could not be kept alive, but after various durations of existence from 2 to 18 months they finally disappeared. One of the dwarfs above named, which we have called The Bride, fertilised with the pollen from another distinct hybrid has, however, produced some very healthy seedlings. . . . We would beg to recommend all who intend practising this very interesting branch of horticulture, no matter what class of plants they propose to operate on, to choose the parents, whether species or hybrids, as far removed from each other as is consistent with the constitution of the plants and the result aimed at."

The interest in the genus rhododendron is increasing to a very marked extent.

Digitized by Google

Much time and effort are being given to the introduction of hundreds of new species, and cross hybridisation is now being carried out on such a large scale that the flora of the gardens of the future (if there are any gardens) will be very different from that of last century.

Excellence of constitution is of the utmost importance, and it is essential that attention should be given to such points as that raised by Messrs. Standish and Noble.

In considering, first, the seeds that come from the botanical explorations of China, that great home of rhododendrons, it is difficult to imagine that they are not the result of fertilisation by self pollen. Unfortunately, I have never had the opportunity of visiting those Meccas of all flower lovers—Yunnan, Szechuen and Hupeh—but I cannot think that the pollenisation question differs there from the conditions prevailing here among many acres of old-established thickets of R. ponticum. In these I find that fertilisation appears to be generally carried out by the conveyance of the pollen to the stigmas by multitudes of humble-bees. While it is possible a bee may arrive from a different species and carrying its pollen, this is to a large extent lost in the first corolla it enters. True, this particular ovary may be cross hybridised, but when it is considered that this is only one flower of a truss and only one truss of many thousands, the odds against the seed of that particular ovary germinating and growing to maturity must be prodigious. The bee, however, then proceeds from flower to flower and truss to truss, and consequently the ovaries are practically all fertilised with pollen of the same bush and, in the majority of cases, the same truss, and, if the statements of Messrs. Standish and Noble are correct, the progeny must be inbred and, consequently, weaker. In the natural habitats of the genus this would not appear to be of importance, as I am told seedlings are seldom seen, considerations of light rendering germination impossible. Also, that regeneration occurs *en masse* usually after fire, and that possibly an entirely different species then appears. Consequently, the fertilisation by own pollen in the main would have no effect, evil or otherwise.

But it is surely altogether different when the seed of this natural fertilisation is collected, sent home and grown here. The betting is greatly in favour of the truss having been fertilised from the pollen of its own flowers. From this seed possibly only a limited number of seedlings are grown. If the plant is good, practically everybody who possesses one of these seedlings endeavours on its first flowering to propagate it by seed from self-fertilisation. In many cases this must also be carried out with the next generation and possibly farther, and, in consequence, if inbreeding is detrimental the constitutions of the eventual seedlings must be sadly impaired. A great deal of experimental work would be necessary before a definite statement one way or the other could be made, but so far I have been much impressed by the very slow growth of R. discolor × self as compared with R. discolor × R. discolor, the latter seedlings being more than three times the size of the former and infinitely more virile. R. discolor has been crossed with a multitude of species and hybrids, and generally, I think, the most outstanding feature so far is their excellence of growth. For instance, R. discolor × R. B. de Bruin (a somewhat dwarf hardy hybrid) promise to be rhododendrons of great size. On the other hand, I think I am correct in stating that seed of R. auriculatum has only been sent home under one number (Wilson No. 920) and I have been told that there are under fifty of the original plants in this country. But there are now very large numbers of seedlings from these plants, and all those I possess or have seen are vigorous to a marked degree, making in their very youthful stages a couple of large growths each year. But these form no conclusive argument, as careful tracing of the parents would be required.

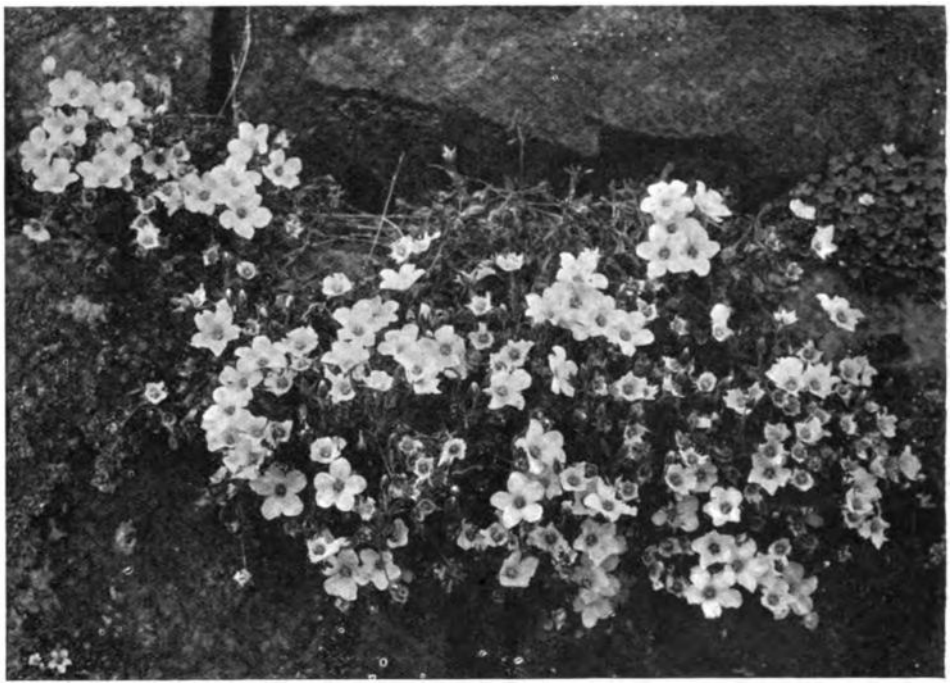
It has been said that the many species in the same phylums of some of the series are caused by geographical separation. If so, and if the progeny of widely separated (geographically) parents are more robust, a great field awaits the hybridiser. Such crosses as arboreum (blood red) × Delavayi (blood red), Thomsoni × Meddianum, sino grande × præstens, croceum × Wardii, Hookeri × Meddianum, barbatum × strigillosum, neriiflorum × hæmatodes, sanguineum × hæmaleum, Farrers 979 × Hupeh Fortuneis, auriculatum × diaprepes, sulfureum × Boothii or theiocroum, and an infinite number of others suggest themselves. Purely from a garden point of view, the offsprings of these crosses should be practically identical with their parents as far as leaves and flowers are concerned, and I wonder how their constitutions would compare.

In view of what is happening to-day in rhododendron cultivation, perhaps some of your readers would express their opinions. A learned botanist's verdict would be particularly helpful, especially, if possible, confined to this particular genus.—J. B. STEVENSON, *Ascot*.

[This subject of inbreeding appears to be of such general interest that we shall be pleased to receive the views of our readers.—ED.]

THE MOUNTAIN SANDWORT.

A FAVOURITE with all lovers of white-flowered alpine plants is that hardy, spreading European Sandwort, Arenaria montana grandiflora. It is adaptable to almost any soil and position, and, once established, blossoms with the utmost profusion, the large pure flowers being thick enough to create masses of crystal white. It is indispensable on the rock garden, where it soon carpets large areas and tumbles down in rivulets of blossom between the boulders. Of this pretty genus this is the largest-flowered kind, and is here seen growing between the sandstone blocks of a low retaining wall. Little or no soil is used in the building of these walls which form such happy homes for small plants, a mere scattering of sand or fine soil sufficing to balance the stones. The plants depend, of course, on the border in their rear for nourishment. The packing of large quantities of soil between the layers of stone—a course often adopted—is not to be recommended for many reasons. As a broad edging to raised beds of flowers this pretty sandwort could scarcely be surpassed, for do what one will the rolling lines of bloom insist upon falling over the edge and into the path in a very picturesque way. Quite recently I saw it scrambling through the branches of Abies excelsa nana, the



ARENARIA MONTANA GRANDIFLORA AT GRAVETYE.

face of which was embedded in snowy whiteness up to a height of 2ft. It is easily increased either by division of its roots, cuttings in early autumn or seeds in spring.—E. MARKHAM.

ROCK GARDENS UNDER GLASS.

I ENCLOSE photographs of two old greenhouses which are now used as indoor rock gardens. The smaller illustration is the outside view taken from the north-west, and shows the general arrangement. Outside against one wall there is a rockery which hides the brickwork and gives one a chance to compare inside and outside behaviour of plants. This outside rockery tends to hold moisture and gets some shelter from the east. It was planted up in spring with all sorts of things to fill up, and they made quite a brave show until the frost came. I had a few of Kingdon Ward's new Chinese primulas growing here and Gentiana Farreri did quite well, but the autumn was too wet to let me save seed and increase my stock.

The larger of the two houses is the old alpine house with an inside rockery, and this was completed before the larger and more elaborate house in the Royal Botanic Garden, Edinburgh, was begun. Plants did well in it until my gardener was called up for Service, and then the house was more or less left alone.

It is possible to make out the leaves of Primula verticillata on the first step on the top, and a little farther in is Rosmarinus prostratus, and still farther off in an intermediate position P. marginata is putting out new leaves. We had frost outside on one night—down below 10° F. in the screen and the soil inside the house was frozen well in.

The other illustration shows my later house. It is a moraine, and along each side, buried just under the ventilators, is a perforated pipe which can be turned on or off as required, and thus supply underground water to plants that are in a permanent position. This house has been filled up with pots to make a show, but there are a few things planted out in it. Halfway along on the right side is a colony of P. malacoides, but this has been supplemented with pot plants to make a brave show. Those permanently planted stood the frost I mentioned above. On the same side, right in the corner, will be seen heads of P. Mooreana. This plant has been in flower since August.

THE NEW AND OLD HOUSES.

The older house is better adapted in the matter of ventilation and light for growing hardy alpine plants, for the newer house was designed originally for growing cypripediums in a moist atmosphere. I cannot yet say whether the ventilation is right, but the two houses give some variety where it may be desirable.—WM. LOW, *Balmakewan, Maryhirk, Kincardineshire.*

[If other readers are accustomed to this phase of gardening, we shall be glad to receive their views.—ED.]

EUCRYPHIA PINNATIFOLIA.

HAVING had considerable experience with this shrub in various parts of the country, I would like to add a few notes to those now appearing in THE GARDEN. Probably up here in Scotland, like the colder and less favourable districts of England, the planter, as "Formakin" (page 9) remarks, must possess his soul in patience. But in the south and the western counties plants raised from seed and planted out in a good free soil will generally flower profusely in their fourth or fifth year; at this stage the plants should be 3ft. to 4ft. high. Many at this size can be split up with ease. I find, like the Donard Nursery Company (page 37), that seedlings vary considerably both in habit and flower, some forms growing very quickly and quite erect, while others seem to make up the difference by branching out into bush form—doubling is rare and not desirable.

Although good specimens are sometimes seen in odd and often sunless corners, in my opinion they seldom reach the standard attained when planted in the shrubbery or grown as lawn specimens, provided they get plenty of well rotted manure or decayed leaves, and are not too much exposed.

So far, I have had no occasion to resort to the saw when propagating, but can quite imagine it being done with complete success when the necessity arises. I find patience is most needed when striking cuttings, for it is a considerable time before they emit roots. Where E. pinnatifolia is known to be a success it might be made more use of, especially in some formal gardening schemes, and in some cases in place of the pergola. Erica carnea might then be used as an edging plant, and early bulbous plants could be introduced without interfering greatly with the plants' development. An annual top-dressing of old potting soil and spent mushroom dung will prove beneficial and to many is preferable to farm manure. Here, E. cordifolia is more at home than E. pinnatifolia.—J. T. H., *Dupplin Castle Gardens, Perth.*

A PORTION OF THE INDOOR ROCK GARDEN.

THE SNAKESHEAD.

THERE is much to be said in favour of the view expressed on page 49 by "N. H. P." that the snakeshead fritillary thrives best when the ground has a covering of some live plant over its roots. I have never seen a mixed bed of the chequered and white variety in the garden grow with such vigour, variety and numbers as in a meadow being grown for hay near Oxford, where the plant is native. In some meadows that were pastured by cattle the plants were scattered thinly over the ground, but the hayfield was practically purple with the flowers of the fritillary, just overtopping the rank grass. Many shades of purple were to be seen, and the darkest ones were the most distinctly chequered. Pure white ones also occurred. The soil must have been as full of bulbs as if purposely planted.—HORTULANUS.

TREATMENT OF SEEDLINGS

BY L. B. STEWART,
Of the Royal Botanic Garden, Edinburgh.

THE introduction of seed into this country has for the past few years called for a large amount of attention from the gardener, as he has been handling such a quantity of new material never in cultivation before.

When collectors, like Mr. G. Forrest, send home seed, the seed packets are numbered; if not, the genus is mentioned, *e.g.*, Aconitum sp., etc. It is always advisable to have the collector's numbers running consecutively when sowing; then finish off the sowing with the genera alphabetically arranged. Where there is a large genus to deal with, such as Rhododendron, it is better to keep all the species together, having them numerically arranged, thus making it easy to get into touch with any of them at short notice.

When germination starts, the pots should be gone over every day, and each one as its seeds germinate should be removed from among the sowings to a separate bench and kept there until the seedlings are making their leaves beyond the cotyledons. Following this, they should be put into a house or frame with a cooler temperature, where they will remain for a time making growth, and in due course be pricked out. This operation should be done at the earliest period, as it is found in this establishment that the sooner the seedlings can be handled the more success is met with. I think if the seedlings are left until the roots have all interlaced before removing, it will be found that they get a severe shock and never attain their full growth, often having disastrous results. We always prick out rhododendrons at the earliest moment—just when the young plants have finished making their seed leaves.

Often it will be found, however, that the amount of seed to be handled is too great in proportion to the size of staff and accommodation that can be given to it; then, of two evils always choose the lesser. Such seed as meconopsis, primula, campanula, roughly speaking, all herbaceous and alpines, must be sown and handled the same season. The exceptions to the rule, however, are cotoneaster, berberis, castanopsis, quercus and betula; if there is not time to handle these the same season they should be sown thinly and allowed to remain in the seed pots until the following season, when it will be found that a great many will be ready to run out into nursery lines. If they have not attained a size for planting out in the nursery, they can be allowed to become fairly dry, after which the earth should be shaken off the roots. They may then be potted singly or pricked out in pans or boxes. The following is, I find, an excellent plan for liliums and nomocharis: Sow thinly and leave in seed pots until they have gone to rest, then plant out in frames or boxes. Although I have observed that with some liliums which are pricked out, like ordinary seedlings, they often make a second growth, but my experience is that they are better left until they rest before shifting.

After pricking out has gone on for a month or six weeks, it will be found that many of the first batch are ready to be put out in an ordinary cold frame. At this time it is advisable to arrange the plants in their groups—Herbaceous, Alpines, Shrubs, Trees—with each genus in rows and numerically arranged. Should there be members of any of the genera which have evergreen and deciduous species these should be arranged, deciduous and evergreens separately. As the season goes on it will be found that the herbaceous plants do not go to rest all at one time, and as each one goes to rest it should be removed from among the growing seedlings in order to get proper treatment. This is only done for the convenience of watering, as it is not practical in this case to do this individually, for it is much easier to water in community. The moving, although taking a lot of time, has a great advantage, as it prevents the roots from rooting through the pans or pots into the ashes, sand or soil in the bottom of the frame, avoiding the breaking of roots which so often causes the death of the plants. The alpines which have been raised and pricked out are best kept in a cool frame or small pit by themselves, as they can be better handled and prepared for planting out, as many of their larger neighbours are very apt to overcrowd them. If once they are overcrowded, they become unhealthy and many die. In preparing the alpines we find, in this northern area, that plants do best planted out of small pots—nothing larger than 3in.—because the pockets in some rock gardens are so small and planting out should be done with as little disturbance as possible to the roots. If done carefully the plant will get little check, if any. I think it is a great advantage to move plants by stealth, so that they are unaware of having been moved.

Temperature is one of the things which require a considerable amount of study. In the springtime, when we begin to get sunny weather, one has to be on the alert to prevent quick rises of temperature and the airing must be regulated with the greatest of care. Never force up the temperature to day-heat with fire, unless it is evident that the sun is not likely to come out. However, if the sun refuses to come out, a little more fire heat will be required, but then only keep it at the minimum dry temperature. During the past few weeks we have had very trying weather—one day and night hard frost, the frost registering 13° Fahr., the next day very mild, the temperature rising to 48° Fahr. maximum. Under such conditions the keeping of seed pits or frames at an equal temperature is somewhat difficult, but big fluctuations should always be avoided, and this may be done by heating, or covering frames with mats or straw. Where hot-water pipes are employed big fluctuations need never occur.

Watering is always an all-important matter with regard to seedlings. When the seeds are first sown in the Royal Botanic Garden, the first watering is always done by placing the pots in a tank or large saucer of water, as near to the temperature of the house in which they are to be germinated as possible, and this treatment goes on during the whole season. After the seedlings are out in the frames, before watering them the water which is taken from the outside tanks must in many cases be heated. This prevents the young plants from getting chilled. After they have passed the seedling stage, however, the care of temperature of the water is somewhat relaxed, although I think, and have proved many times, that by kindly watering many deaths have been avoided.

In potting seedlings the main point to be observed is the root system of the plant. A plant which has a straggly root system needs much more care than does a plant which has a very fibrous root system.

We come now to the time when we are receiving seed from abroad. Never should packets of seed be laid aside with the saying, "We will sow in the spring." As all practical gardeners know, there are seeds, such as quercus, magnolia, elm, crinum, etc., which may be termed viviporous seed, and which should be sown at once. At this time of year it is not advisable after sowing to place these seeds into too much heat, but just to keep them moving until they "catch the season," when you will find that you have far healthier plants and very much bigger plants. If placed in heat the growth is either short and stumpy or of a very long-drawn-out structure, which in a lot of cases causes a "C 3" progeny. The hard-seeded ones may also be sown and put into a dark place—underneath a stage. The remainder of the importation may then be left and stored until spring. The labels of these can be written now in order to save time later in the spring, when there is so much to be done.

It will often be found with seed coming from abroad that the seed coats have become impregnated with different kinds of moulds. Many of these moulds are distinctly harmful to the germination and growth of the seedling, and should be got rid of as quickly as possible. When the seed is large enough to handle easily, we wash it in the Garden here in a 5–10 per cent. solution of permanganate of potash, and when the seed is small it is treated in the seed pots by watering with a fine rose. This solution kills the fungi, seems to stimulate the seedling, and hastens its germination, and when applying the water solution it should be of the same temperature as the house or frame in which the seed-pots are kept.

CANTERBURY BELL CULTURE

BY H. W. CANNING WRIGHT.

PROBABLY no other member of the great Campanula family enjoys quite so large a measure of popularity as does the Canterbury Bell. Certainly none of the biennial species does. Not only are they "easy to grow," but very beautiful, and one is sure of a long, lasting and abundant display of their glorious flowers, with but a minimum of attention.

The first point, naturally, that arises when considering their culture is sowing the seed. Obviously, the best results must follow where the plants that are put out in autumn consist of those giant rosettes of leaves which only follow a long period of steady growth—the result of early sowing. Experience and observation have taught us that the usual period—May or June—is too late, and that late March or early April are far better, especially where the plants are to be used for pot culture for flowering about Christmas time, although

Photo Carter and Co.

A FINE COLLECTION OF CANTERBURY BELLS UNDER GLASS.

it is a remark that applies with equal force where ordinary open ground culture is to be followed. Shallow boxes, filled with light, rich, rather sandy soil made very fine on the surface, are the best receptacles in which to sow, and this, of course, should be thinly done. The merest scatter of soil over the surface is sufficient covering and, if placed in the greenhouse, only the most moderate temperature should be used. April sowings only need a cold frame, and once the little plants are up and have formed three or four leaves (whether raised in heat or not), no time should be lost in pricking them out in the nursery beds where they are to grow until the autumn.

Rich soil is not at all necessary, provided it has been well dug and a reasonable amount of manure added during the winter; while, too, a semi-shaded spot will serve quite as well as a sunnier one. Give the seedlings sufficient space—1ft. from plant to plant is not excessive in the case of these early sowings—and, beyond an occasional watering during dry spells and free hoeings to keep down weeds, the plants will make but small calls upon your time during the summer.

Before leaving the subject of seed sowing, attention may well be directed to a very charming but somewhat unusual use of the plants, *i.e.*, growing in walls. Their effect here is splendid and, owing to their adaptability to growing well in poor soils, they give excellent results where but a modicum of earth exists. In this case we much prefer to sow the seed *in situ*, rather than transplant the roots, and a good method to follow is to scoop out a hollow between the stones that form the wall and fill this tightly with fibrous loam. Place some moss in a small bowl with just a little water, add enough loam to form a stiff paste, and then take up enough of the mixture to form a small ball, drop a few seeds into this and push it firmly into the prepared wall pocket. It will be necessary to see that this soil is kept just damp during dry times until the seedlings are well started, and not more than one plant should be allowed to grow at each point. Once well started, they are quite capable of taking care of themselves and bear long droughts without injury.

Reference was made above to their culture in pots for flowering about Christmas time, and this is extremely easy, for they will do so, either then or at a later date—with the most moderate inducement in the way of artificial heat. For this purpose the plants should be lifted from the nursery beds in September and potted up in 8in. or 10in. pots, according to the size of the plants. Drain the pots freely—the Canterbury Bell detests stagnant moisture—and use a compost consisting of two parts fibrous loam to one of old manure, and sufficient sharp sand to make the whole feel thoroughly gritty. Pot firmly, without making hard. Place the pots in a cold frame until established, then admit plenty of air. The plant is perfectly hardy and will stand a good deal in the way of cold, but one does not want hard frost to injure the rosette of foliage. All dead and decaying leaves should be removed, water very moderately and—during October—introduce into a very cool greenhouse where plenty of air is admitted. When the centre begins to spindle up into the flowering stem, support by a light strong stake and feed with weak but varied liquid manure.

In the open ground, a great point should be made of getting the plants into their flowering quarters *early*. They are splendid for following annuals, etc., as this permits their being put out during the first half of September, and far better results follow this method than where the work is deferred until later. Do not forget the point that they detest an ill-drained soil and that you may plant either in full sun or partial shade with assurance of success.

Lavish massings give the best effects, although here and there specially vigorous plants may be set out singly. In this case they will, with rich soil, attain a similar height to pot-grown specimens—2½ft. to 3ft.—and become pyramids of blossom from base to tip. As the first flowers pass, the plants should be gone over with the scissors and all faded blooms be snipped off, while the soil may be watered with a little sulphate of ammonia. This causes the secondary buds to swell and develop, and but a short interval will pass before your Canterbury Bells are again a mass of bloom.

As tub plants on lawns and terraces, the Canterbury Bell is capable of forming noble specimens that will prove a formidable rival to the fuchsia when they are more widely appreciated in this direction.

In raising from seed, only a proportion will come true, especially among the doubles, while even singles vary in colour. The Cup and Saucer varieties are among the very best as equally good in pots or the open ground.

Biodiversity Heritage

WEEDS AS HOST PLANTS FOR INSECT AND FUNGOID PESTS

BY A. J. MACSELF.

THE indictment of weeds as criminals of the garden embraces counts of major and minor importance. Robbery of nourishment from the soil is undoubtedly among the majors; but, whatever may be said about their untidiness, and of the evidence the presence of weeds affords of careless and negligent husbandry—and these are very real and very true—they should certainly be called minor evils compared with the serious and dangerous count against many kinds of weeds that they act as host plants for insect and fungoid pests.

It is somewhat strange that we hear and read considerably less about this sinister vice of weeds than we do of their greed of nourishment and their untidiness; but if careful thought is brought to bear upon the matter, it must be realised that the harbouring of pests and diseases is by far the worst of the three evils.

If weeds steal nourishment from the soil, it is, at any rate, possible to replenish that nourishment by applications of manures and fertilisers, albeit the extravagance merits censure; but if weeds are allowed to serve as a refuge and breeding ground for all manner of pests they menace the healthy occupants of the garden and probably nullify the benefits that should accrue from any remedial measures employed upon infested and diseased plants.

It is of little use, for instance, carefully to spray roses or other plants to free them from a plague of green fly if a colony of sow thistles near by is allowed to remain teeming with aphis. The theory that different species of aphides attack different classes of plants is all very well up to a point, but there is not enough difference between the green fly one may find on weeds and those that infest calceolarias and the roses to render the latter immune from the unwelcome attentions of the ever increasing hosts of the weed-fed insects.

The recumbent foliage of a dandelion may afford shelter and food for slugs, and the thoughtless may say, "Let them feed away." It is all right when the slugs eat weeds, but the trouble is, there is no gaurantee that the slugs will remain on the dandelion, but a big risk that they will, sooner or later, migrate to the lettuces or the pansies. Chickweed, spreading prostrate over the ground, is another cosy shelter for slugs, and at night out they will come, to vary their diet upon the most appetising seedlings and young shoots around.

One of the most prolific nurseries for aphides is the hirsute foliage of Hieracium Pilosella, a pretty enough little plant, but a most persistent weed, especially on lawns and grassy banks. Every flower stalk becomes densely crowded with greenfly, and it is no unusual thing for ants to transport the young aphides from their overcrowded home to the tender young shoots of plants near by, where they may feed and grow fat, to yield payment for services rendered by exuding honey-dew upon which the ants will feed. The hieracium often establishes itself on banks at the foot of the hedges around a garden. It is prudent, therefore, to extend weeding operations even to the hedges and ditches, where often caterpillars as well as green fly are bred.

The frog hopper or froth fly breeds freely on weeds, and the mature insects will travel from them to chrysanthemums and many other plants of the herbaceous border. It may be readily understood that if an odorous spray fluid, or a bitter wash such as quassia and soft soap, has been used on a batch of plants, a moth or fly, seeking a suitable leaf or twig upon which to deposit her eggs, will hesitate to select the sprayed plants. If, however, a clean healthy batch of weeds with soft young growth happens to be close at hand, the trouble of further search is avoided, and instead of a clean slate so far as that particular pest is concerned, the weeds will serve to maintain the stock. The troublesome white fly is quite frequently able to find refuge among weeds when fumigating starts. It is not only in regard to insect pests, but, perhaps even to a greater extent, with fungoid diseases that weeds are a menace. Even the common groundsel will frequently be literally smothered by common mildew, or in times of drought with one of the summer rusts that develop when a plant is stunted and weakened. It often happens that the small, starved plants that crop up between the stones of a yard or path become afflicted with disease while healthier and stronger plants escape. With all these spore-producing, parasitical diseases the smallest foothold is sufficient to start what may easily, under suitable atmospheric conditions, develop into a veritable plague. The dreaded hollyhock rust will develop on wild purple mallow, and several of the potato diseases affect the solanums in the hedges. Leaf-curl, shot-hole fungus, cladiosporums in variety, and puccinias will all be found sooner or later where neglected corners are choked with weeds, and spores or mycelium will eventually get to valuable plants.

The common-sense conclusion to which these facts lead is that herein lies one of the greatest—if not, indeed, *the* greatest—of all reasons why weeds cannot be tolerated in the garden or orchard, nor even along the hedge banks and ditches or in the odd corners around the rubbish heap. It will, moreover, be very apparent that the mere chopping down of weeds, or the process of uprooting them and allowing them to lie on the ground will not suffice. Spores of fungoid plant diseases, eggs and pupæ of insects may fall to the ground and lie dormant until a favourable moment for activity arrives, and to this fact may be attributed the sudden and mysterious outbreak of trouble on a batch of plants that started with much promise.

Old weeds should be pulled up, placed directly into a basket or barrow, and conveyed to a rubbish fire. Only perfectly clean young weeds should be dug in, and only the smallest of young seedlings allowed to remain on the surface after hoeing.

These precautions are an essential part of a really well planned campaign against the enemies of the garden.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Cauliflowers.—To maintain a succession another sowing should be made, and if the ground is dry enough and a warm border is available a sowing may also be made outside. Sow the seeds thinly in lines one foot apart and select such varieties as Early London and Magnum Bonum.

Lettuces.—Both cabbage and cos varieties may be sown in the open providing the soil is not too wet, if so it will be best to utilise boxes and raise the plants in a cold frame. When large enough to handle, the seedlings may be transplanted on a warm or sheltered piece of ground, but before this is done they should be well hardened off. Two of the best lettuce I grew last year were Ideal and Golden Ball.

Turnips.—Although it is early to sow turnips in quantity, it is advisable to make a beginning with Snowball or some other small white variety. Here again a warm spot is advised and only a few lines should be sown. Protection from birds will be necessary.

Celery.—During the next week or two sowing of celery is recommended, choosing Solid White and Sulham Prize. Sow the seeds thinly in boxes containing light soil, and place them in a warm house or on a mild hot-bed until the seedlings appear. Keep the young plants well up to the light, and do not let them suffer for the want of water. When the plants are large enough to handle, prick them off in boxes or a cold frame about 3ins. apart. A mixture of loam and leaf-mould or manure from a spent mushroom bed will make a suitable rooting medium, and if

Digitized by Google

a cold frame is selected it should be set on a hard bottom. Gradually harden the plants before pricking them off, and when the weather is mild admit air freely.

Spinach.—Make another sowing of spinach on a piece of ground which has been dug deeply and afforded a liberal dressing of manure. Spinach is often sown between lines of peas, but if it is decided to sow elsewhere, the rows should be about fifteen inches apart.

THE FLOWER GARDEN.

Herbaceous Borders.—Many leave the digging and manuring of these borders until the present time or early in March, but much depends on the season, and in any case such work should be completed as soon as possible. There is still time for planting, and, no doubt, early spring planting has its advantages: the roots soon become active, and there is often less trouble with slugs.

Petunias.—For a sunny garden petunias are strongly recommended, and perhaps for beds the large-flowering single varieties are the most showy. Seeds may be sown during the next few weeks in pans containing light soil and the seedlings raised in a warm greenhouse. Prick them off when large enough, and if the sun is strong they will need a little shade until they are re-established. It is advisable to prick off all the small seedlings as they often produce flowers more richly coloured than the strong-growing plants. Keep the seedlings free from aphis and do not allow them to become starved.

Border Chrysanthemums.—A good supply of cuttings is now available on old stools that were lifted and placed in a cold frame, while several varieties left in the open ground are also well furnished with young shoots. These will readily form roots if placed in pots or boxes containing sandy soil, and arranged in a warm pit or greenhouse. A cold frame will also suffice, but, in this, damping off should be watched for, and decayed leaves removed immediately. Young plants produce the best flowers, but where any variety is scarce the old stools may be planted out later on.

THE HARDY FRUIT GARDEN.

Old Fruit Trees.—These will be greatly benefited by applications of liquid manure, and I remember one orchard containing rather aged trees that received three or four good soakings annually and the fruit improved in quality. In most gardens manure is scarce owing to motor transport, but in many places the liquid manure pit is still available, especially where cows are kept, and it ought to be utilised to the best advantage. Liquid manure should be given when the ground is more or less moist and not during a dry period.

Autumn-planted Trees.—Specimens that were planted early in the season may be lightly pruned about this time. Strong shoots should be cut back about one-third of their length, and weaker growths pruned to three or four buds, or entirely removed if they are likely to crowd the centre of the tree.

Raspberries.—The autumn-fruiting kinds will need attention during the next week or two, the canes being cut down to the ground level, and if not already done beds that have not been transplanted should be afforded a mulch of farmyard manure. There is still time to make new plantations. When the new growths appear they should be well thinned. Some of the autumn fruiters, especially the Hailshamberry, produce a large number of shoots which, if left alone, would become a mass of weak growths that will only produce inferior fruit.

FRUITS UNDER GLASS.

Melons.—Now is a good time to raise a batch of plants which will ripen their fruits when the sun is strong. The fruits will therefore be of excellent flavour. Small well drained pots should be chosen and filled with light soil, and it is advisable to place them in the warm house or pit a few days prior to sowing the seeds. When the soil is warm sow the seeds singly, and if the compost is not too dry no water will be needed until the seedlings appear. A temperature of 65° to 70° is essential during the day with a fall of 5° or so at night. A cucumber house is excellent for growing young plants of melons, but when they reach the flowering stage different treatment is necessary. When the small pots are filled with roots, the plants may be transferred to receptacles 5ins. in diameter and kept well supplied with tepid water.

T. W. BRISCOE.
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Horseradish.—Vegetative propagation is the usual method by which this plant is increased. Pieces of the roots should be secured now and placed into holes 8ins. deep—made by a dibber—in good and well trenched ground. The holes should be 1ft. apart and about 2ft. allowed between the lines.

Onions.—Where seedlings are well advanced they should be set out into boxes containing soil that has been firmly pressed. Prick out the seedlings carefully at 1½ins. apart. Keep in a moderately heated house or frame and shade from bright sunshine until re-established.

General Work.—If a spare frame or portion thereof is available, a little of the following seeds should be sown: cabbage, cauliflower, Brussels sprouts, leeks and lettuce. Continue to forward the digging, manuring and trenching of all vacant ground.

THE FLOWER GARDEN.

Foxgloves.—Masses of these plants when in flower in woodland or vale are a charming sight. Here we have a large number of plants raised from seed, and these we shall set out now in open places in the shrubbery.

Herbaceous Borders.—The autumn is the best time to trench and replant these borders, but where the planting has been delayed it should now be carried out. Some kind of plan should be worked to as regards colour harmonies and arrangement, also see that every plant has a proper station at proportionate distances. This applies more to formal borders of medium size, and where varied plants are set to give of their beauty over as long a period of the year as possible. Each plant or group of plants should be labelled, so that an intelligent interest may be taken in their care and cultivation.

Roses.—If climbing roses have become overgrown, they should be taken down from the poles or rustic erections and properly pruned by cutting out all dead and worn-out wood. Select the young and best placed ripened stems and from these cut away all small side shoots an inch from the stems. Afterwards replace and tie the pruned stems to the poles, etc. Where rose planting of any kind has yet to be done, have the work completed at once.

THE HARDY FRUIT GARDEN.

Apricots.—The training of the trees should now be taken in hand, and more progress will be made in mild weather than on cold days. If time is available, all old shreds should be cleared from the stems, so that nothing likely to harbour dormant insect life is left about the trees. Next space out as uniformly as possible—3ins. apart may be taken as a guide—all properly matured wood, cutting out all spindly and badly placed shoots to two or three buds from the base. All prunings and old shreds should be burnt. For a top-dressing loam, old lime and sea sand, mixed in proportions of four parts loam to one each of the others, will be found suitable. Before applying see that the soil, especially near the base of the wall, is not in a dry state. Sometimes violets are grown at the base of wall fruit trees, and these plants are a hindrance to top-dressing.

Cherries.—These trees, and indeed all wall fruit trees, should be made secure to the walls and the young wood laid in where necessary. The pruning of the Morello consists in cutting out all old and worn wood and retaining the young wood except where overcrowded. The other kinds of cherry trees bear their fruits on spurs. The soil recommended for apricots may be used as a top-dressing for all stone fruit. Farmyard manure may be applied to apple and pear trees.

Small Fruits.—It is not too late to plant or transplant young currant or gooseberry bushes; however, the work should be completed at once. The soil between the bushes of established plantations should be lightly forked over and the plants mulched with farmyard manure.

Spraying.—As soon as the pruning is completed spray the trees. Bentley's Concentrated Alkali applied according to directions and in the proportions given on the tins is to be recommended. Apply with a fine spray; this wash will burn the moss and lichen on the stems. Choose a calm day for the operation and take the precaution to wear strong gloves and smear the face with cold cream or vaseline. All places on the old wood likely to harbour insect life should be thoroughly sprayed.

FRUITS UNDER GLASS.

Figs.—Prune trees on walls by cutting out all weak and overcrowded wood. Afterwards cleanse the stems with Gishurst Compound and then tie up the trees.

Peaches in the late houses should now be in full bloom, and the work of pollinating will call for daily attention. A small soft-haired brush or a rabbit's tail tied to a stick will be found very useful for going over the flowers. Ventilate the structures freely on all fine days, and hive bees, if in the vicinity, will enter and industriously work among the blooms. In early houses, where fruit is set, syringe the trees daily during fine weather.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

GREENHOUSE AND CONSERVATORY.

Clianthus puniceus.—Although this fine plant can be successfully grown in pots, it is seen at its best when planted out in a cool greenhouse, trained up a pillar or back wall. C. puniceus can be either propagated by means of cuttings or seed, the latter method being best. If seed is sown at this time quite good plants may be obtained for next year. Germinate the seed in heat, but the subsequent cultivation should be carried out in a cool greenhouse. This plant is somewhat subject to attacks by red spider, which, however, can be held in check by regular syringing.

Clianthus Dampieri.—Commonly known as the Australian Glory Pea, this lovely plant has always, and not without reason, been regarded as difficult to cultivate successfully. Although one sometimes obtains good plants raised from seed and grown on their own roots, one is more likely to be successful if the plants are grafted on young seedling plants of Colutea arborescens (Bladder Senna). The operation should be carried out when bot-

Digitized by Google

plants are in the young seedling stage. As the plants are so young and soft, great care is required. In performing the operation, the tip of the young seedling colutea should be cut out close down to the cotyledons and the soft skin then split downwards with a sharp knife. The young seedling clianthus should then be cut off near the ground line, trimmed to a wedge shape, and then inserted in the split stem of the colutea. Afterwards carefully bind it round with a strand of soft cotton. The young plants should then be stood in a close case or under a bell-glass. If the work is carefully done the young plants should unite in a few weeks, when they should be gradually accustomed to more air. As the season advances and the plants increase in size they should be grown in an ordinary greenhouse temperature. These plants are very impatient of disturbance at the root, thus great care should be taken when repotting. Perhaps the most effective way of growing these plants is to place several of them in a basket. Where it is desired to grow this fine plant from seed, the latter may be sown from now onward, it being an advantage if the seed pots can be stood in a warm propagating case until germination takes place. The plants grow quite well in any good potting compost, but the pots should be well drained and water carefully given at all times. Red spider should also be guarded against.

Tibouchina semidecandra, if planted out in the conservatory should now be pruned hard back, except where shoots are required for extension purposes. Some of the slender twiggy shoots may be used at this time for propagating purposes, as they root readily in a close case. Although seen at its best when planted out, this plant may be successfully grown in pots. Plants raised at this time will flower during autumn and winter. To keep them bushy and compact they should be pinched frequently during the growing season, and freely exposed to sun and air in a cool greenhouse.

Bouvardias.—Plants that have been at rest and kept dry and cool should now be started in a warm house. They should be shaken out and repotted into the smallest pots consistent with the size of the plants. If it is desired to increase the stock by means of root cuttings, some of the stoutest roots should now be secured from the older plants. Cut into pieces about one inch in length and dibble in pans containing sandy soil. Stand the pans in a warm propagating case. The variety Bridesmaid does not come true from root cuttings, always giving a proportion of Hogarth fl. pl. Later on the old plants will have made young shoots about three to four inches in length, which should be secured as cuttings. At this stage they root readily in a warm case. During their growing season bouvardias should be frequently pinched to induce a bushy habit, and if desired may be planted during the summer months. By this means fine large plants can be obtained.

Achimenes, are very useful for greenhouse decoration during the summer months. Some of the more slender varieties being very useful for filling baskets; in fact A. coccinea seems to succeed best when grown in baskets. The rhizomes should be laid out in leaf-soil and sand, and placed in a warm house. When they have made growth about two inches in length they should be placed in suitable sized pots, or pans, six-inch pots being large enough for the strongest-growing varieties. These plants enjoy a light rich compost with ample drainage. They are very subject to attacks by begonia mite and white fly. The former can easily be prevented by the use of the sulphur vaporiser, while the latter should be kept in check by fumigating with sodium cyanide or some other approved remedy.

Epacris as they pass out of flower should be cut back and stood in a house with a temperature of about 50°. At this stage they enjoy a higher temperature than Ericas. They should be encouraged to break into fresh growth by frequent spraying during bright weather. If repotting is necessary it should be done when they are starting into growth.

J. COUTTS.

Royal Botanic Gardens, Kew.

BOOK REVIEWS

STANDARDISED PLANT NAMES.

THE efforts over a period of five years of the American Joint Committee on Horticultural Nomenclature have culminated in an octavo book* of about 550 pages, which is supposed to be "a catalogue of approved scientific and common names of plants in American commerce." It is sincerely to be hoped that its publication may lead to the desired standardisation of names by American nurserymen, but for various reasons the writer thinks it doubtful. It does not seem feasible that a nurseryman, to please the Committee on Horticultural Nomenclature, will be willing to mislead his customers by listing Thuja occidentalis under that name and its weeping variety under the totally dissimilar description of American Weeping Arborvitæ. This is bad enough, but the purchaser would readily identify the plant offered, but what can one say for Robinson Anemone as an improvement on Anemone nemorosa Robinsoniana? One realises at once that the plant described in the old way—the way still current here—is a variety of the wood anemone, but only by consulting the "Standardized Plant Names" can one form any picture at all of the growth or stature of the Robinson Anemone. Moreover, what is to happen if and when some of the other numerous varieties of our wood anemone are introduced into American commerce? Presumably we shall have Allen Anemone, Purple Anemone and a host more, all without a label indicating their species.

Another drawback to the list is that it is not, unless one is greatly mistaken, complete. Can it be that no single species or variety of androsace is at present in American commerce? or that Viburnum Davidii and V. fragrans are as yet not on offer over the water? Should this latter be the case, it only shows how detrimental to American gardening are the foolish restrictions upon the importation of plants.

The Committee have, according to the introduction, taken especial pains with their standardised common names, but some of them are not unexceptionable, for example, European Cranberry Bush for the Guelder rose, Viburnum Opulus; our cranberry being, of course, Viburnum Oxycoccos. The Americans, however, seem to differentiate between "cranberry" and "cranberry bush."

The lists of dahlias, irises and gladioli seem more fortunate and useful than any other part of the book and will, it is to be hoped, be adopted by the American trade.

A list of standardised plant names is badly wanted in this country, but it is sincerely to be hoped that if and when it is undertaken the promoters will be less drastic and more practical in their recommendations. The American list could have been, in any case, of little use "on this side," because of the different and wider range of plants cultivated here. Almost the only use of the present issue in Britain—apart from the lists of gladioli, irises and dahlias—is in case one wishes to buy plants from the United States, and then only if the American horticultural trade adopts the nomenclature, which scarcely seems likely.—W.

* STANDARDIZED PLANT NAMES. Published by American Joint Committee on Horticultural Nomenclature, Salem, Mass., U.S.A. Price $5.00 net.

ANSWERS TO CORRESPONDENTS.

THE GREENHOUSE.

Geraniums Decaying in Greenhouse (A. L. M.).—The cause of the stems and leaves of the plants decaying is excessive atmospheric moisture. Our correspondent treated the plants correctly in the first instance and partly so in the present. The only thing to do now is to cut back the stems to the hard wood, place the plants in the warmest and driest position, and not apply water till new shoots begin to grow. In the meantime simply remove decaying leaves.

FLOWER GARDEN.

Daffodil Bulbs Unsatisfactory (F. G. L.).—We can find no organism or signs of the presence of any earlier attack in the bulbs sent for examination. We are of opinion that some condition in which the bulbs have been kept since last growing season has been detrimental to them.

FORTHCOMING EVENTS.

February 19.—Croydon Horticultural Society's Meeting.

February 20.—Glasgow and West of Scotland Horticultural Society's Meeting.

TRADE NOTE.

GARDEN ORNAMENTS.—A beautifully illustrated booklet of Garden Ornaments has just been published by Messrs. Sanders and Co., Garden Craftsmen, of Sundial House, 365, Euston Road, N.W.1, which will be sent post free on request. Many unique designs of both ancient and modern sundials, bird baths and vases are shown, with dimensions and prices. These are made in imperishable reinforced stone. Messrs. Sanders and Co. have made a speciality of the "Wycombe" bird bath. It is a very pretty and unique design, consisting as it does of a bath with a simple scroll pattern around the edge, standing on a graceful pedestal and base to a height of 2ft. 6ins., and the price is extremely moderate, viz., £3 18s. 6d. A bird bath of this nature placed in the centre of a lawn or other suitable part of the garden would be of great interest and usefuness all the year round.

South African Plants for Wembley.—By the steamer which left Capetown on February 7th there were shipped nearly two thousand specimens of South African native plants and bulbs which are to form a garden of exceptional interest at the British Empire Exhibition at Wembley. Not only are many of them curious and rare, but varieties will be shown which have only recently been discovered. All of them will repay the most careful attention and study. Once it is known what they are, perhaps the greatest interest will centre round what apparently looks like chips of stones scattered over the soil, for these are varieties of mesembryanthemums which in due time will burst forth into bloom. The whole exhibit owes its origin to the interest taken by Sir William Hoy, general manager of the South African Government Railways, in the beautifying not only of the more important stations, but those lonely wayside halts away on the desert Karroo and on the high veld. There, water cannot be had beyond the requirements of the resident staff, and this condition led to a systematic search for dryland plants which, with Sir William's facilities and energy, seems likely to develop into a service which will be of world-wide importance. Readers should make a note to examine this interesting collection.

GROW MORE FRUIT

WE are beginning, in this number, a series of articles by Mr. Hatton, Director of the East Malling Research Station on "Fruit Growing in Small Gardens." This is a subject which should be brought considerably more to the front, as the cultivation of dessert fruits in our gardens, with the exception of small fruits, is inclined to be relegated into the background. Our imports of apples from Canada and the U.S.A. alone totalled £5,823,864 during 1921. Statistics do not show what percentage of this figure consisted of dessert apples, but the amount must be large. It is this steady flow of fruit, of consistent good quality and attractively packed, that has brought about the decline in the cultivation of our own table fruits.

As Mr. Hatton points out, the demand of the jam makers and cooks has kept up the supply of cooking fruits and in that branch we are able to hold our own, but insufficient grading and careless packing have decreased to a minimum the demand for home-grown dessert fruits, so much so that those of first-class quality have become one of the most difficult commodities to obtain.

It is not with a view of teaching orchardists their business that these articles have been written, for the growth of fruit and its successful marketing are entirely separate. Taking into consideration our climate, as growers of suitable varieties of fruit, we are second to none, but our knowledge of successful marketing is almost negligible. The point, however, which Mr. Hatton does bring forward is that the owner of a garden, whether it be a six rod patch or a garden of several acres, is in a position to supply his household with a large proportion of the necessary table fruit throughout the year. It is true, that as a nation we eat more cooked fruit than the Americans; to them jam is a luxury and raw fruit a necessity, but even in this country the demand for raw fruit could soon be increased, for nothing is more palatable or better for the health than high-class dessert fruit. The Americans make a habit, almost unknown here, of beginning the day with an apple, an orange, a grapefruit, or with some stewed fruit, like apples or prunes. It is an excellent tonic and fruit might well become a general breakfast course in this country.

One of the usual arguments against growing fruit trees in the small garden is the question of space. It is frequently stated that apple and pear trees are picturesque but bulky, and they take up room which is more valuable for growing vegetables or flowers. In the second article of the series will be shown the plans of two small gardens, one badly designed and the other showing how fruit trees can become an integral part of a good garden. In the old days before the question of fruit stocks had been tackled by the scientist the argument about question of space was sound, but within the last few years it has been abundantly proved that a large and good crop in proportion to size can be obtained from an apple grown on a dwarfing stock. This means that they can be grown in a smaller space and that the shadow, owing to lesser height, is not of such a size that a disproportionate amount of ground around the tree is useless for growing other crops.

Probably, the main difficulty with the small grower is the choice of suitable varieties. The number of varieties now on the market is enormous and it is certainly a problem to find out which are the most suitable for your particular locality. The best advice that can be given is to make enquiries in your own neighbourhood as to the kinds which have proved themselves to be most satisfactory. Plant those which have been thoroughly tested in soils and conditions similar to yours and be satisfied with as few varieties as possible, provided that they give you a succession of ripe fruit and do not all come into condition at the same time. Do not be led astray by stories about a magnificent new apple, pear or plum which is sure to do well in your part of the country. If your own fruit trees are satisfactory and bear good eating fruit do not be influenced by a will-o'-the-wisp; let the man with the big garden do the experimenting. If he is a true member of the fraternity, he will realise that you have not the space for fruit trials and should be glad to give you all the information in his power.

Above all, make use of agricultural colleges which have a section devoted to fruit, and also of the Government experimental stations. There are many such institutions scattered throughout the country, as, for instance, the Wye College in Kent, the East Malling Research Station, and the fruit department of Bristol University. They are not there for their own amusement, but to help fruit-growing in this country. They are just as ready to help the small man as the orchardist with thirty acres. The pamphlets issued by the Ministry of Agriculture should also be better known. Your own bookseller is always able to obtain them through H. M. Stationery Office.

AMONG OTHER ARTICLES IN OUR NEXT ISSUE WILL BE:

NEW AND RARE CONIFERS, by E. H. Wilson of the Arnold Arboretum.

HERBACEOUS PÆONIES IN ENGLISH GARDENS, by Mrs. Edward Harding.

FRUIT-GROWING IN SMALL GARDENS.—I

BY RONALD G. HATTON, M.A.,
OF THE EAST MALLING RESEARCH STATION.

THIS series of articles has been written in the hope of being able to give an indication to urban dwellers and to the gardener on a small scale that first-class fruit, both dessert and cooking, can be profitably grown in a small garden. I do not hesitate to say that, if the cultivator of the small garden would but pay attention to the knowledge that is being accumulated and the facts that are being published, he could grow more and better fruit in his garden. Now, by the small garden I do not only mean the acre, half acre or even quarter acre patch, but I am visualising as well the six, ten or twenty rod garden of the average town or village residence. Even the cultivator of larger gardens might take note to-day of some of the morals of fruit-growing in small gardens.

THE AIM OF THE SMALL GARDENER AS A FRUIT PRODUCER.

When the cultivator of the ten rod patch sees wonderful displays of British fruit, like those set before the public at such shows as the R.H.S., Imperial Fruit Shows, etc., he may have the feeling that with all this beautiful fruit available it is not worth trying to grow his own fruit in his own garden. Then his more practical wife reminds him that most of the fruit she buys does not approach in quality what she sees here, that she very often has to pay dear for inferior stuff and that there is nothing better for health or better to taste than really fresh fruit picked straight from the bush or tree.

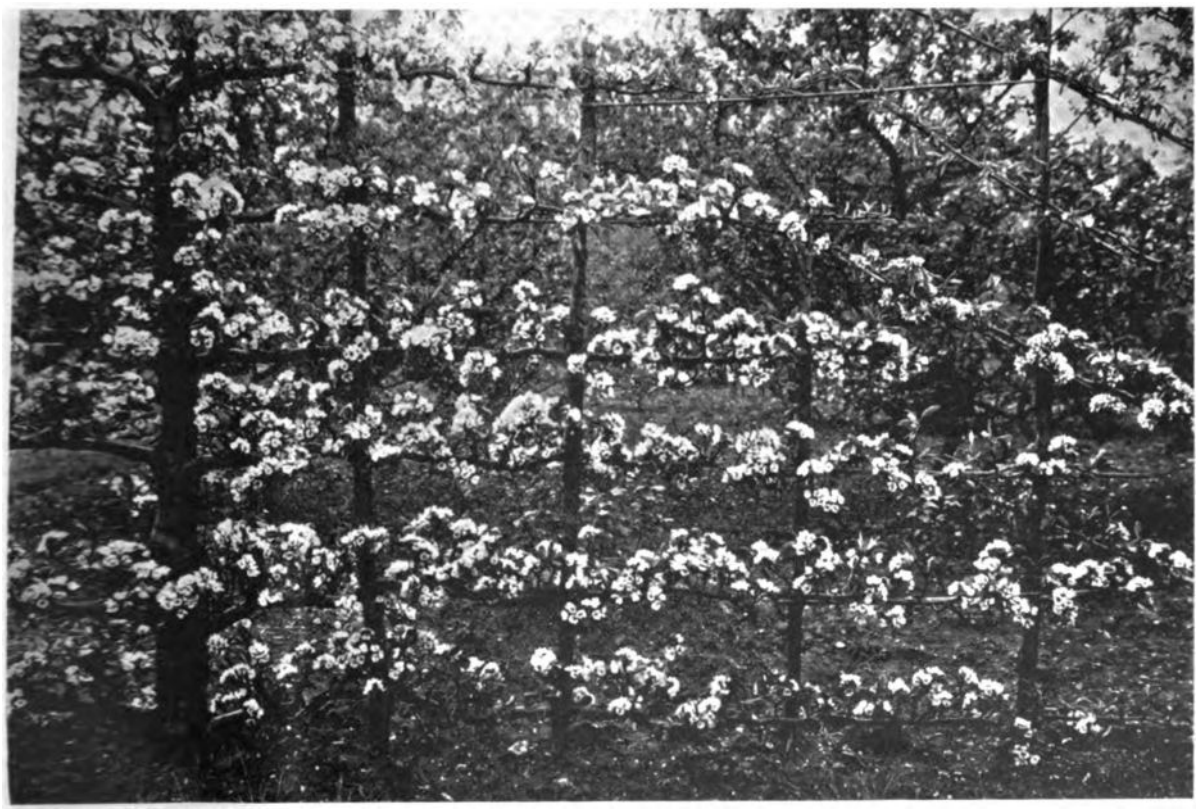
She can buy so-called "sweet eating" or "good cooking" apples, descriptions which may cover a multitude of sins, but who can guarantee her the genuine Cox's Orange or Ribston Pippin or the Royal Sovereign strawberry instead of Madame Kooi! She may even have suffered as I have, and wandered about a Kentish town and been offered only inferior Cox's Pomonas when I sought first-class Cox's Orange Pippins!

Now, the cultivator of the small garden usually has many claims on his limited space. As many vegetables as possible are required for the home, a few flowers must be there to brighten the house; perhaps, even, a corner has to be reserved for the poultry or rabbits. How can he hope to be his own supplier of fruit? Certainly if he expects to keep his family supplied with culinary and dessert fruits throughout the season he is an ambitious man. Rather he will be wiser to limit his scope. Only too often, I must confess, I think he does this in the wrong direction. He gives up the attempt to grow all those high quality, subtle flavoured and supremely health-giving raw fruits for the table, and he gets disheartened in the hopeless struggle to try to keep the kitchen in jam and cooking fruits, which is the main idea in the English household of fruit consumption.

Cooked fruits and jam are to be encouraged by all means, but in this country it is only a few who realise the benefit and enjoyment of delicate raw fruits on the table for every meal. They are looked upon as an impossible luxury or as an ornament for the sideboard. There is no need for this and it should not be. While we in England are not developing our taste and discrimination for such delicacies, we find every class of home or public restaurant in America supplying fruit with almost as much routine as they do bread or iced water. Enticing fruit is brought down the corridor of your train; it is awaiting you on every platform.

THE BEST AIM.

I want to persuade the average cultivator of the small garden to have a new ambition, namely, to supply his own table with a succession of fine dessert fruits, a series of wonderful surprises, and to persuade his wife that she can often buy to better advantage the class and bulk of fruit required for jams and pies. I would also like to have them believe there is really a special virtue in raw fruit, and a wonderful range of flavour to be discovered. It must be pointed out that a similar amount of discrimination should be used in choice of fruit for purposes of cooking and jam making. Good cooking fruits, however, are more readily obtainable than really good dessert fruits;



TRAINED TREES ARE JUST AS CAPABLE OF GIVING BEAUTIFUL EFFECTS AS STANDARDS, AND THEY SHADE YOUR GARDEN LESS.

Digitized by Google

the jam manufacturers and the chefs have seen to that, but fruits of eating quality are not so easy to come by.

It is often said that Englishmen eat with their eyes. It is colour, shape and size which attracts, and so we give the buyer what he thinks he wants. But fine feathers do not always make fine birds and I would not mind guessing that at least 80 per cent. of our population have probably never sampled our best quality dessert fruits. It is the production of these that should be the aim of the small gardener and I assure him that given average conditions, provided he will apply ordinary intelligence to his experiment, many of these best varieties are well within reach of attainment.

THE PROBLEM OF FRUIT-GROWING IN THE SMALL GARDEN.

The problem is how to combine fruit, vegetables and flowers so that all have a fair chance, and the flowers and vegetables do not suffer through competition for sunlight and nourishment with the fruit, while the fruit is not robbed of nourishment by predaceous undercrops. There is also the problem of how to use to good effect trees and plants in our gardens, so as to make the small garden a garden beautiful, with its suggestions of space and mystery, things which are so essential to the pleasure of every gardener.

If one comes into occupation of a badly planned small garden, one must steel one's heart and be ruthless, but it is surprising how quickly evils can be redressed provided that action is taken.

The problem of fruit-growing in the small garden is merely one of arrangement of planting, of scheming, of insisting on an orderliness which in itself can be beautiful. It is merely a resolution to resist certain temptations, to look ahead, and avoid certain common pitfalls. These might almost be presented as a series of maxims.

INITIAL MAXIMS.

1. ON PLANNING.—Never overcrowd your garden with fruit trees or bushes. Plan beforehand and steadfastly refuse to find room for just one more tree presented by some kindly neighbour. Plan your whole fruit garden in advance and then accomplish the plan by degrees.

2. ON USE OF DWARF TREES AND NOT TOO VIGOROUS VARIETIES.—Never overshade your garden with fruit trees. Do not plant tall, vigorous standard trees in every odd corner. Insist on dwarf trees wherever possible for a small garden. If you require a tree to afford shade to sit under, select your variety carefully and choose a site where it will not keep all the sun off your garden.

3. ON TRAINED TREES.—Be persuaded that beauty does not always consist in picturesque untidiness, in sprawling trees and spreading branches. Trained trees are just as capable of arrangement to give beautiful effects of screening, distance, etc., and they shade your garden less. They are handsome both in flower and in fruit, while many a little alcove can be formed of espaliers even in the smallest garden, where a favourite plant can be sheltered, or tea drunk in warm weather. For the amount of room they take up, their bearing surface is greater than in the case of standards, and the fruit is more easily handled.

AN APPLE WHICH HAS BEEN TOO MUCH PRUNED. THERE WILL BE LITTLE OR NO FRUIT.

4. IMPORTANCE OF SUITABLE VARIETIES AND STOCKS.—Never plant a "fruit tree" or "bush" or "a raspberry," "currant" or "strawberry." Be certain what variety you are planting. Some varieties are quite unsuitable for gardens in general, others may be quite unsuited for your particular conditions. You cannot be too inquisitive about the name or about the root stock on which the tree is worked.

5. ON SPECIAL SUITABILITIES OF CERTAIN FRUITS AND SITUATIONS.—It is very little good trying to grow certain fruits by certain methods in the small garden. The single standard sweet cherry tree will be the property of the birds as well as a good look out post for them. Avoid filling your small wall space with such uncertain bearers as greengage, Kirke's Blue plums, or Doyenne du Comice pears. There are plenty of other good things that will crop more certainly and regularly. Yet you can make use of all your walls and fences, poles and arches on which to grow some kind of fruit. It is better to grow a few canes or bushes of a heavy cropping good thing than several rows of a poor cropping inferior one. Find out the good thing and be sure you get it.

6. ON PRUNING.—Do not illtreat your trees or bushes by too much attention with the knife. Remember the more you cut away in winter the more wood you will get next summer, and, generally speaking, less fruit.

7. ON KEEPING DOWN DISEASES AND PESTS.—Realise that you will be extremely lucky if you can grow good fruit regularly without attempting to control their diseases and pests. Like human beings trees want constant hygienic precautions and occasional doctoring.

8. ON MANURING.—You cannot continue to take good crops of fruit and vegetables off your land without putting something back. The latter is not so difficult as it sounds.

A TYPICAL OVERCROWDED GARDEN. IT AUTIFUL AND THE FRUIT
TREES ARE SO OVERGROWN THAT T DE THE VEGETABLES.

GREENHOUSE CYCLAMENS

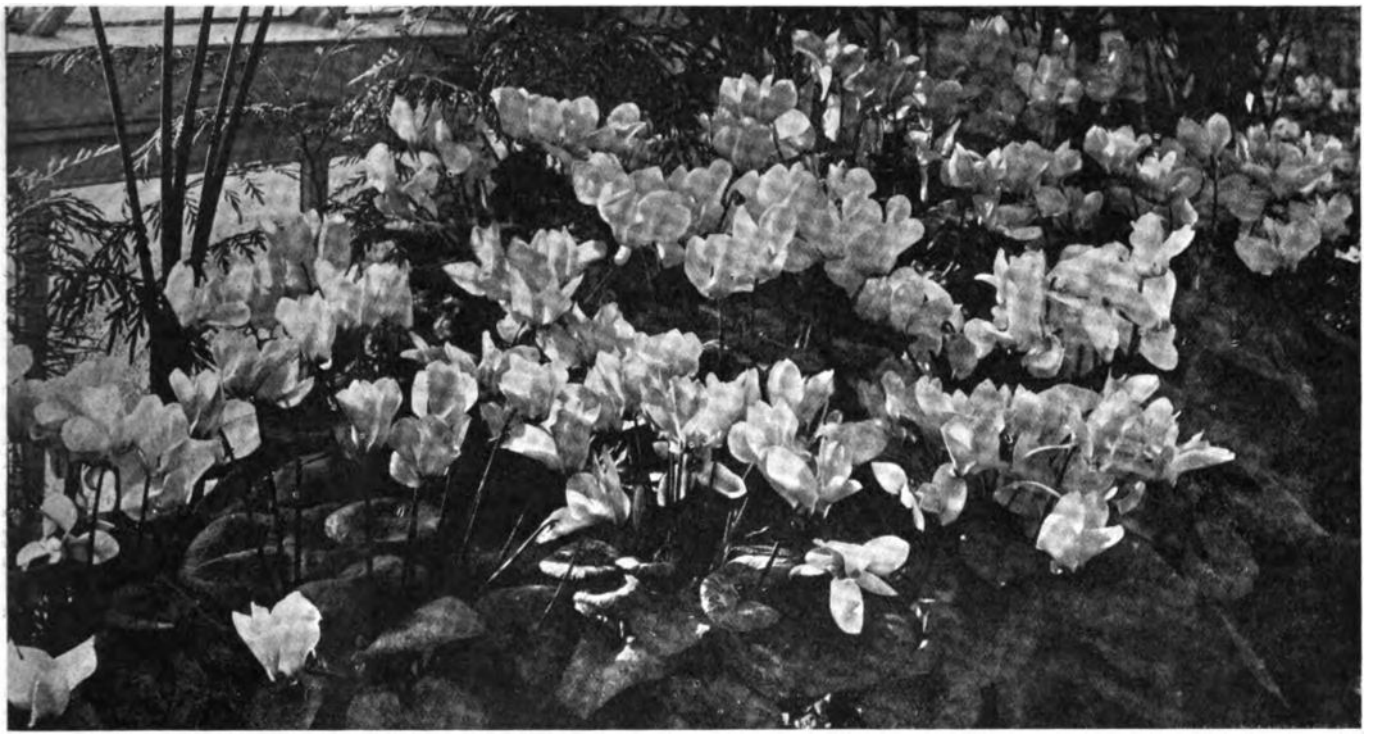
BY J. COUTTS.

CYCLAMENS in many beautiful varieties are more or less indispensable, not only for furnishing the stages in the greenhouse and conservatory, but also for house and table decoration. The cut flowers last for a long time in a fresh condition. Cyclamens belong to the Natural Order Primulaceæ; there seems to be some doubt as to the actual date of their introduction and cultivation. The many varieties cultivated at the present day have been obtained by seed selection.

Cyclamens are easily raised from seed, but it is very important that the latter be fresh. Old seed is often slow and uncertain in germination. It is the general practice to sow seed during August, the resulting plants flowering about fifteen months later. On the other hand, it is possible, with good cultivation, to flower the plants in twelve months from seed sowing. From seed sown at the end of December or the beginning of January I have frequently produced good flowering plants within twelve months. However, it should be remembered that such results are only possible out in the country where there is plenty of light during the winter. In the immediate neighbourhood of London and other large towns I would advise sowing about the middle of July. However, for general purposes it is best to sow seed about the middle of August. The compost for sowing should be light and open, consisting of a good medium loam, with the addition of some leaf-soil and enough silver sand or old mortar rubble to keep the whole open and porous. I advise the use of old mortar rubble in preference to sand at all stages of the plant's cultivation, as I consider that lime in some form is essential.

The compost in the seed-pans or boxes should be made fairly firm and the seeds sown singly about one inch apart and a quarter of an inch deep. As germination is usually irregular, this method allows of the more forward plants being taken out without unduly disturbing the others. The seed-pans should be well watered, covered with pieces of glass and kept shaded until germination takes place. The seeds may be germinated in an ordinary greenhouse, but it is an advantage if they can be placed in slight bottom heat, or at least in a warm moist house where a temperature of about 60° can be maintained. After the seeds have germinated, the seed-pans should be placed on a shelf well up to the roof glass.

About the beginning of November the bulk of the young seedlings should be ready for pricking off into pots, pans or boxes, according to the quantities required. At this stage some cultivators place the seedlings directly into thumb pots, but on the whole they are best pricked off into pans or boxes until January, when they may be potted off singly into pots. During the winter months they are best grown in a warm moist house where a temperature of 55° to 60° can be kept up. As they increase in size and the season advances they should be accustomed to cooler conditions, and during the summer months they are best grown in low pits or cold frames, where they can be kept well up to the roof glass. It is also an advantage if the frame lights can be pulled off, as towards the end of summer the plants benefit greatly by dews at night.



FOR PURITY OF COLOUR AND GRACE OF OUTLINE FEW GREENHOUSE PLANTS CAN EQUAL CYCLAMENS. THEIR FLOWERS LAST A LONG TIME IN BLOOM.

Towards the end of April or beginning of May the young plants should be ready for a shift into 3in. pots. For this and subsequent pottings a larger proportion of loam should be used, with the addition of a 6in. potful of bone-meal to every bushel of soil, or, where it can be obtained, some dried cow or sheep manure—rubbed through a fine sieve—may be used with advantage. The pots should always be clean and well drained Pot the plants fairly firm, keeping the young corms just on the surface of the soil. From the end of June to the middle of July the most forward plants should be ready for placing in their flowering pots (48's).

Careful watering and the maintenance of cool, moist atmospheric conditions are the essentials of success with cyclamens. Admit plenty of air on all favourable occasions; draughts, of course, should be guarded against. The bed on which the plants stand should be kept moist and the plants sprayed over during the morning. They should also be sprayed again during the afternoon, when the frames should be closed for an hour or so, afterwards giving a little air during the night or the lights may be removed altogether so that the plants get the benefit of the dew. The plants should, of course, be kept shaded during bright sunshine. When grown in frames

Digitized by Google

A FINE SHOW OF THE BEST VARIETIES OF CYCLAMEN.

it is an advantage if cyclamens are stood on inverted pots, thus allowing the air to circulate freely among them.

Towards the end of September plants in cold frames should be removed to span-roofed pits or a cool, airy greenhouse, keeping them well up to the glass. When they have well filled their flowering pots with roots, they may be fed with diluted liquid cow manure and soot water. Sheep manure is also excellent for the same purpose.

If desired, some plants for early flowering may be brought on in a slightly warmer temperature, remembering, however, that the best results are obtained by cool treatment. Cyclamens can be grown on for several years, but at the present day it is usual to raise them from seed each year. If it is decided to grow some of the plants on, they should after flowering be stood in cold frames, watering them in the usual way. As the old foliage gradually dies off, the plants should be kept on the dry side for several weeks, and when they show signs of starting into fresh growth they should be turned out of their pots and all the soil shaken off the roots. Afterwards place them in as small pots as possible. After potting, stand the plants in a cold frame and water very carefully until some new roots are formed. When they have well filled their pots with roots they will require a shift into larger-sized pots, the cultural details being the same as that advised for the young plants.

Instead of potting off the old corms, some growers plant them out in a bed of rich soil in cold frames, or even outdoors, lifting them and placing them in pots during September.

With their beautiful marbled foliage and elegantly poised flowers cyclamens are ideal for decorative work, plants in cool rooms keeping in good condition for many weeks. Cut flowers are also excellent for decorating dinner-tables and for filling small vases. The flowers should be pulled out, not cut, as the decaying end is apt to affect the young buds, which are thickly clustered on the top of the corm. The hard end of the flower-stem should be cut off and the cut flowers placed at once in water, for if allowed to flag it is difficult to get them up again, especially so with the giant varieties. If flowers are sent for any distance, they should always be placed in water for several hours before packing. If some moist material is wrapped round the ends of the stems and the flowers packed tightly in tissue paper, I have always found them travel well. When unpacked, the stems should be split upwards for several inches and the flowers placed in water as soon as possible. The smaller-flowered varieties, I may say, generally carry best.

If cyclamens are kept too warm and in a dry atmosphere, aphis and thrips may prove troublesome. Fumigation will, however, prevent and hold them in check, but if correct cultural methods are followed these pests should not cause any trouble. Begonia mite, or so-called rust, is, however, much more serious, and although it may not appear during the summer when the plants are in cold frames, it often proves troublesome during the autumn and winter when the plants are growing in a warmer and drier atmosphere. This pest damages both the foliage and flower-buds, causing the latter to become deformed and marked with brown streaks. The best preventive and cure for this pest is the occasional use of Campbell's Sulphur Vaporiser. Where houses are infested with vine weevils their larvæ often prove very destructive, harbouring right under the cyclamen corms and feeding on the roots. All plants which suddenly flag without any apparent reason should be examined, and if larvæ are found, they should, of course, be destroyed. Again every opportunity should be taken to destroy as many weevils as possible. At night, plants should be shaken over a white sheet or tarred trays; houses should also be kept clear of all rubbish and broken walls repaired.

There are now many beautiful varieties of cyclamen which come true from seed. Messrs. Sutton and Sons of Reading have perfected many fine varieties. Their giant varieties in white, salmon, crimson, rose and pink being very fine. Their smaller-flowered Firefly received an award of merit in 1923 from the R.H.S. The silver-leaved salmon variety, too, is very beautiful and worth growing for its foliage alone. This firm also offer a sweet-scented strain. For lovers of the curious there are crested, frilled and fringed varieties These are, of course, interesting as showing the wide range of variation in this plant, but cannot for beauty of form and poise compare with the ordinary forms.

[*We are indebted to Messrs. Sutton and Sons for permission to use these pictures.*—ED.]

RHODODENDRON POISONING

THERE have been several letters in the papers lately about stock being poisoned by eating the leaves of R. ponticum, but there seems to be some doubt as to what extent rhododendrons are poisonous. The first mention of poisoning by rhododendrons is no doubt that in Xenophon's "Anabasis." We have not a copy of the book handy for reference, but as far as we can remember there is a passage where Xenophon states that during the return march of the "Ten Thousand" to the Black Sea many of the men were poisoned by eating honey made from rhododendrons.

Mr. H. C. Long in his monograph on "Plants Poisonous to Livestock," one of the Cambridge Agricultural Monographs, states that there is no doubt as to the poisonous character of a number of species; and, indeed, that many of them are suspect. Animals do not seem greatly addicted to eating them, but there are a sufficient number of records of stock having been poisoned, particularly by R. ponticum. Other species which are definitely stated as being poisonous are R. maximum, listed as one of the thirty most poisonous plants of the United States of America; R. ferrugineum, as having caused frequent poisoning of sheep and goats; R. californicum which is certainly poisonous to sheep in Oregon; and R. chrysanthum, which has caused poisoning in human beings, although the leaves are used in Russia as a cure for rheumatism. Hooker in his Himalayan Journals mentions goats as having been poisoned by R. cinnabarinum.

Digitized by Google

Cases of human poisoning are not so common. Hooker mentions the poisonous character of honey collected when R. arboreum is in flower, but the most noticeable example is on the Burma-Chinese frontier where some of the tribes are very fond of honey and keep bees. They know enough to throw away the honey during the flowering season of the rhododendrons, but they make a kind of mead from their honey. They occasionally go on the rampage for several days with this liquor, and when their old stock is used up they become careless and make it from rhododendron honey, when the result is disastrous. As many as seven deaths have been recorded in one village as a result of a drinking bout.

On the other hand, all rhododendrons cannot have the same amount of poison, for the Chinese for many years have been accustomed to use rhododendron leaves for flavouring certain kinds of tea, although we believe that it is unknown what species they use. It is a possibility that the more aromatic a rhododendron the less poison it contains. Both leaves and flowers are toxic.

Several toxicologists have worked on rhododendron poisons, and they have found that the toxic principles are arbutin, ericolin, rhododendrin and andromedo-toxin, which are all glucosides. Arbutin contains glucose and hydroquinone, and occurs also in arctostaphylos and in all ericaceous plants. It is used in medicine and also as a vermifuge for dogs; ericolin is an inert glucoside which is also found in arctostaphylos. A German toxicologist states that both of these glucosides are cerebro-spinal poisons. About rhododendrin comparatively little is known.

Andromedo-toxin is, however, the most poisonous principle. It is a bitter glucoside and has been regarded as even more poisonous than aconitin, the poisonous principle of aconite.

Glucosides are especially active when a ferment is present as in the stomach. The symptoms of rhododendron poisoning in animals are diarrhœa, salivation, vomiting, trembling, spasms, vertigo, loss of power and death, while a reddish colour is imparted to milk.

Little work has been done on azaleas, but it is believed that pontica, indica, arborescens and nudiflora are poisonous to animals in the East. The active principles are said to be arbutin, ericolin and andromedo-toxin. Azaleas appear to be narcotic.

The chances of rhododendron poisoning in this country are slight. Rhododendrons are usually grown either in the garden or in woods, and stock, except an occasional stray beast, have few opportunities of eating them. The other danger, that of eating rhododendron honey, is not alarming. Several humans have eaten this and have suffered from colic as the result, but rhododendrons impart a bitter flavour to the honey and the taste is not attractive. It must also be remembered that in the East during the rhododendron flowering season the bees have great difficulty in finding anything else from which to collect honey, and this is not likely to be the case in this country.

ORNAMENTAL GOURDS

OWING TO THEIR WEIRD COLOURS ANDSHAPES THESE CURIOUS VEGETABLES ARE EXCEEDINGLY POPULAR IN FRENCH HOUSES WHERE THEY ARE USED AS WINTER DECORATION.

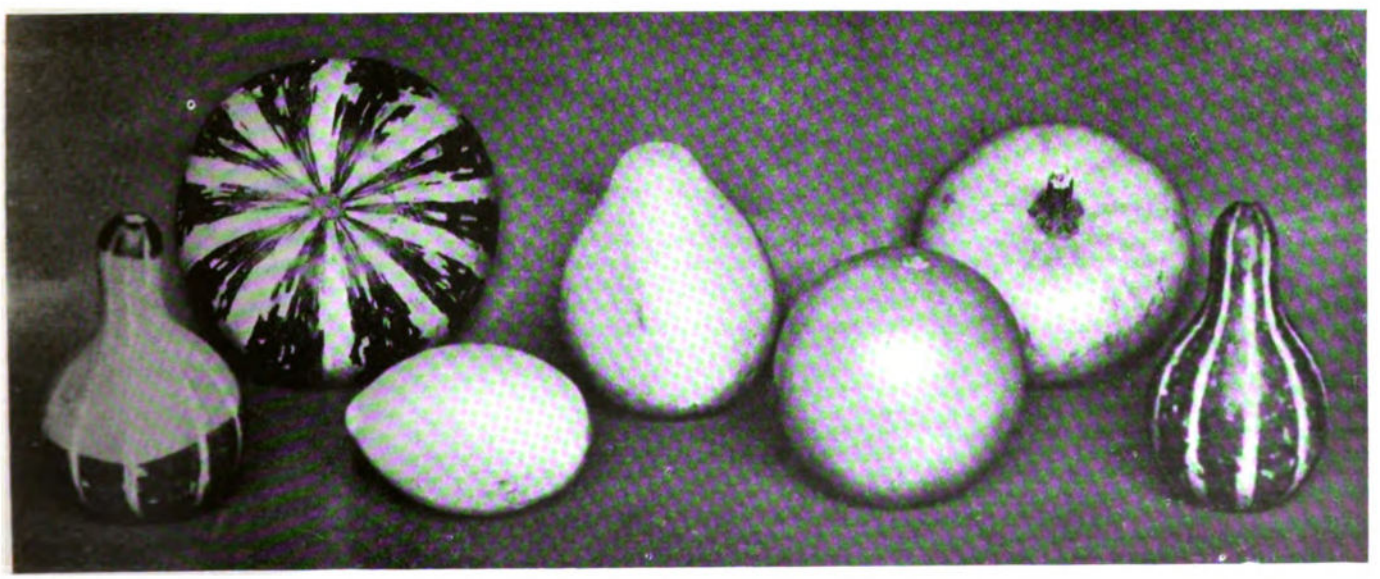
BY E. H. M. COX.

IT is many years since these curious members of the cucurbitaceæ have been popular in England, although they did have a slight measure of popularity about twenty years ago. Since then, by selection, the most extraordinary forms and shapes have been evolved in France, so much so that during the past two years a craze for these curious vegetables has arisen in Paris. They are used entirely for house decoration, for with the exception of one, the 'Patisson orange,' they are so uninteresting from the culinary point of view as to be unedible.

Incidentally, it seems to be extraordinary that the vegetable marrow has entirely ousted the pumpkin, another of the gourd family, from our list of vegetables; the latter has infinitely more flavour and is the basis of a most delectable dish, pumpkin pie. Vegetable marrow pie is unthinkable.

In France these ornamental gourds are considered to be easier to raise than melons and on the authority of M. Louis de Vilmorin I can state that they should be no more difficult to cultivate in England than in France. They are grown either on a hot bed inside a frame, in which case they are sown in March, or they are sown during April and May direct on a warm border, trenched and heavily manured. No doubt the former method will prove more satisfactory in England, where the sun heat is not so strong as in France.

The fruits mature in August and September. They should be picked when the weather is dry and stored in a warm, dry atmosphere where the air can circulate around them (a good plan is to hang them up), for a week or two, after which they should keep perfectly during the winter. If these simple

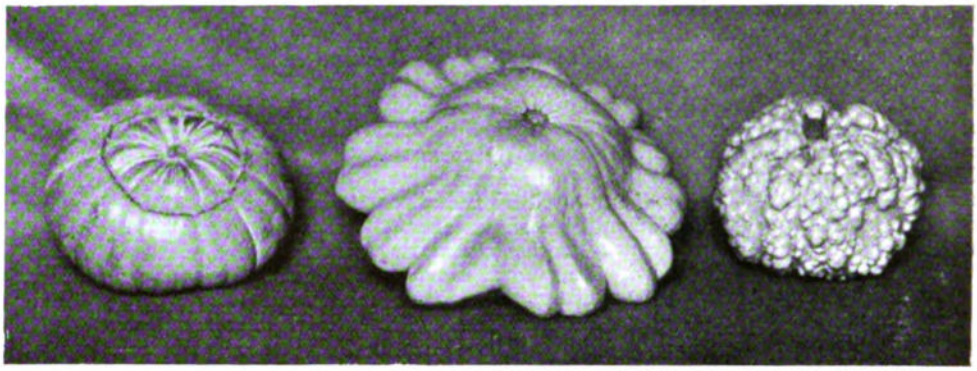


A COLLECTION OF "COLOQUANTES."
The "orange," is third from the right and is an exact facsimile of a real orange. The striped varieties are glossy green and palest citron.

Digitized by Google

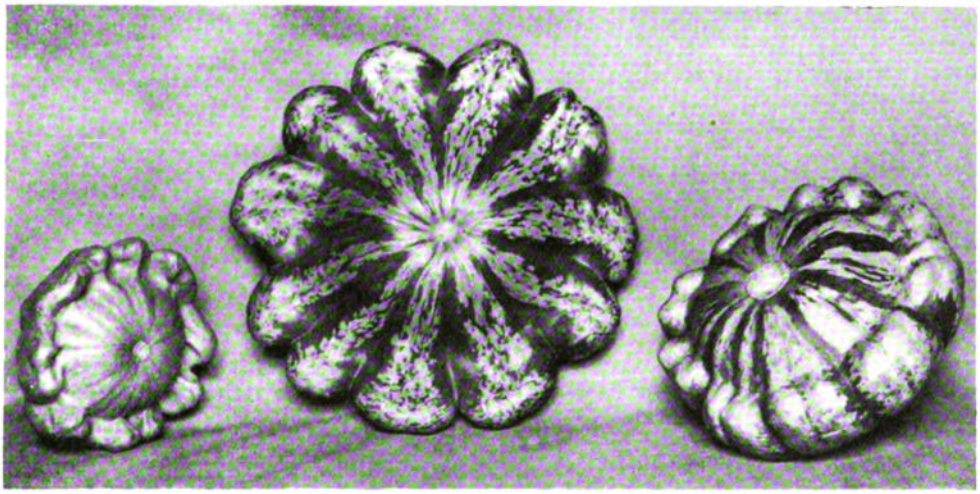
precautions are not taken, they may sweat and rot will set in.

Through the kindness of M. de Vilmorin I brought back with me to England the different specimens shown in the illustrations. The commonest kind in France, which you can buy anywhere for about 1½d. each, are those which they call "coloquantes." The varieties are numerous, brodée galense, plate rougée, orange, pomme, poire blanche, oviforme blanche, etc. They are all small, from two to three inches in length or in diameter. They are of all shapes, like an orange, a pear, an elongated fig, an egg and so on. The colour is usually pale lemon yellow or orange with a white stripe, or green with a citron stripe, or a combination of green and orange.



GIRAUMON PETIT DE CHINE ON THE LEFT PATISSON ORANGE IN CENTRE; THE FIRST IS VERMILION AND THE OTHER PUREST ORANGE.

The coloquante orange is a particularly good imitation of an orange and I was told of the story of an orange grove in the South of France in a popular holiday resort. There is an open air restaurant in the grove and the proprietor used to be annoyed at the idea of oranges hanging on the trees as decoration and not being a paying commodity. Now they are all harvested and sent to market and in their place he hangs up hundreds of coloquante oranges just out of reach of the guests. These are all grown in the back yard, and, although this plan has been in operation for several years, the change has never been noticed. Another attractive variety is that called Giraumon petit de Chine, which is vermilion in colour with darker stripes at the base. It is circular in shape and rather flattened at top and bottom; it is usually about six inches in diameter.



DIFFERENT FORMS OF PATISSON; THE COLOURS ARE GREEN AND CITRON. THE CENTRE ONE IS ELEVEN INCHES IN DIAMETER AND WEIGHS ABOUT FIVE POUNDS.

But the finest of all the ornamental gourds are those which the French call Patisson, or Bonnet d'electeur, or Artichaut de Jérusalem (why the last name?). They are in two forms, both like the head lamp of a motor car, with frilled edges, but in one the frills extend outwards and upwards, while in the other they curl in and fold round the base. Some of them are of enormous size and weigh twenty or more pounds, but the most convenient sizes are those which average eight to ten inches in diameter. In colour they are either primrose yellow, orange (a most brilliant colour) and panaché, a curious mixture of dark green and palest yellow stripes.

As decorations these gourds are most attractive. They last throughout the winter, indeed I have seen some three years old as fresh as if they were grown yesterday; they fill a bowl with rich colours when rich colours are hard to find and they are easy to grow. Why not give them a trial?

GARDENS OF INDIA

THE PEASANT GARDEN

BY SIR GEORGE WATT.

INDIA may be spoken of as one of the greatest agricultural countries of the world. Scattered over the plains of that vast country are clusters of houses which become hamlets, villages and towns, with the growth of population. As a rule the village sites are only very slightly raised above the level of the surrounding country, hence, in localities subject to heavy monsoonic rains, the plains become inundated and the villages are temporarily converted into islands. Intercommunication (for months on end) may thus have to be accomplished by boats (dug-outs) or by swimming with floats made of earthenware pots. And, since large tracts of the plains are below the level of the rivers, the rainwater has to be removed by evaporation. In course of time, however, the water gradually subsides and the country once more becomes dry and is seen to bear heavy crops.

THE SEASONS.—The periodic return of the rains divides the year into three seasons—the hot season, from April to June; the rainy season, from July to October; and the cold season, from November to March. But the seasons vary considerably with changes in latitude or altitude. So again the physical features of the soil exercise a marked influence on the distribution of plants. The extremes may be indicated by the rainfall of 500ins. a year, in the Khasia Hills, and from that through every gradation to the practical absence of rain in the deserts of Central India, Rajputana and Sind; or illustrated by the tropical plains of the lower Provinces to the arctic snows of the upper Himalaya.

THE CROPS.—Viewed from the standpoint of crops it may be said that at least two crops a year may be taken off the same soil, a fact sometimes spoken of as the vertical acreage. The crops of the rainy months of summer and autumn are known as *khariff*, and of the cold months, October to April, as *rabi*. The former are the tropical crops—the millets, rice, cotton, sugar-cane, indigo, etc.—and the latter the temperate—wheat, barley, pulses, mustard and rape, linseed, opium, tobacco and most of the garden crops. As illustrative of the diversity that prevails, it may be said that a visitor to India, were he able to travel from one end of the country to the other, in one day, might witness wheat-land being prepared, wheat being sown, see wheat half grown, wheat fully ripe, wheat being reaped, and, finally, wheat grain being brought into market.

THE PROFESSIONAL GARDENER.—With so great a diversity in climate, soil, crops, etc., it may readily be understood how difficult it must be to speak collectively on any aspect of Indian horticulture. But without fear of contradiction it may be said an Indian

Digitized by Google

gentleman (the amateur) gardener—the person who takes pleasure in his plants and himself works in his garden, because of the healthful exercise it affords, is unknown in India. Horticulture is entirely in the hands of several castes, of whom the Mali and the Koiri or Kachi may be accepted as representative. By the European residents, every man who works in a garden is a mali. As a matter of fact the malis proper rarely, if ever, work in the gardens with their hands. Their chief occupation is the preparation and sale of the bunches of flowers, offered to the idols, and the manufacture of the wreaths and garlands employed at marriages and other ceremonies. They also do a large trade in supplying the Gandhi or perfume maker with the flowers he requires. In practically every village of India there is at least one mali. His services are as essential and technical as are those of the Brahman, than whom he is, by caste, only slightly inferior. The malis are, moreover, the chief owners or tenants of such garden lands as exist. They direct and control the actual workers, so that from time immemorial the traffic in votive offerings and ceremonial garlands has very largely guided operations in the floral gardens of India. Flowers that could be readily strung (corollifloral for choice), of a white colour and possessed of a penetrating odour, were preferred.

EUROPEAN INFLUENCE.—The arrival of the European gave a completely new turn to Indian gardening. The desire for diversity and novelty changed the character and composition of the gardens and it seems to have been early recognised that India might practically grow the plants of the world. Cultivation for a purely æsthetic purpose became a dominant feature. This is seen by the fact that the suburban villas erected by Europeans, during the sixteenth to the eighteenth centuries, were spoken of as "Gardens" both by the Natives and the Europeans—hence the suburb of Calcutta, known as Garden Reach. But let it be here added that the Europeans, in their desire for improvement, introduced into India many foreign plants and to such an extent was this carried that, perhaps, half the plants now under cultivation, as well as the weeds of waste places, have been introduced within historic times. Many of these have proved unquestionable boons, others have become a constant annoyance and offence. The Portuguese were the first great adventurers in acclimatisation, and many of the useful and ornamental plants now met with abundantly in India are due to the early traffic of that people between India and America.

CLASSIFICATION OF INDIAN GARDENS.—It may be said that in India to-day there are four distinct types of gardens :

(1) The indigenous peasant garden, which, in most cases, might perhaps more accurately be described as house-door cultivation, for it must not be forgotten that the bulk of the peasants of India have no gardens of any kind.
(2) The Native gentleman's garden.
(3) The village market garden.
(4) The European garden.

The third is by far the most important, since the extensive system of market gardens that prevails contributes, to a very large extent to the diversity of the minor products that constitute so striking a feature of India's modern trade and commerce. In fact, the transition from the market garden to the field is often inseparable and such articles as tobacco or opium may be field crops with one cultivator and market garden products with another.

THE PEASANT GARDEN.

Peasant gardens, in the majority of cases, are owned or worked by members of the gardener caste. But even in the better examples they consist of but a courtyard a few yards in length and breadth, enclosed by a fence which has the additional purpose of supporting climbing plants.

THE HEDGE.—The fence, therefore, calls for some consideration. It is constructed originally of dead thorn twigs, supported by certain hedge plants, such as the milk hedge (Euphorbia Tirucalli), or its cousin the *rangchitra* (Pedilanthus tithymaloides), an interesting plant with thick, fleshy leaves that appear subsequent to the pink slipper-like flowers. Both these plants have the merit that cattle will not touch them. But they are foreigners, the former having come from Africa and the latter from the West Indies. Very often two American plants form part of the hedge, namely, the so-called American aloe (Agave Cantula), and the *nág-phana* or prickly pear (Opuntia Dillenii). In Upper and Southern India the *henna* (Lawsonia alba) makes a hedge very much like privet and its leaves, dried and reduced to a powder, afford an orange-red cosmetic dye, in much demand by the ladies for colouring the finger-nails, the palms of the hands and the soles of the feet, and by the men for colouring the hair. Another hedge plant is almost cosmopolitan—the *kharata* (Dodonæa viscosa), a plant extensively employed because of its not being eaten by cattle or goats, a property very possibly due to the resinous exudation that forms on the leaves. As a bush it is wild both in the rainless deserts of Central India and in the excessively moist tracts near the sea shore, in the Sunderbunds.

THE TREES.—Much could be written on the plants used in India as hedges, for they are both extensive and varied, more so than in Europe. Within the hedge certain small trees are frequently grown, such as the *saina* (Moringa pterygosperma) or horse-radish-tree, and very useful it is since the leaves, flowers and pods may all be eaten and a valuable oil (*ben*) prepared from its seeds. Another small tree, fairly common, is the *bak* or *agusta* (Sesbania grandiflora), the tender leaves and superb red or white flowers (which look like gigantic sweet peas), as well as the green pods, may be eaten, but while they may not be offered to Vishnu, the *bak* flowers are sacred to Shiva. The *arnatto* (Bixa Orellana), a South American bush or small tree, is also common in the garden hedge, though apparently not introduced into India until shortly before 1833. It is a beautiful plant with curious echinate fruits and large white and pink flowers, clustering in terminal bunches, within the broad graceful leaves. The reddish pulp, formed around the seeds, yields a soft, orange-pink dye, largely employed as a temporary tinctorial agent at the festival of Krishna. Occasionally also it is used as a pigment with butter or cheese and other articles of food.

FLOWERING SHRUBS FOR A MODERATE SIZED GARDEN—II

BY W. J. BEAN.

PRUNUS.—Nearly all the species of prunus, including cherries, plums, peaches, almonds and apricots, are trees, and therefore out of the present discussion, but it may be said in passing that no garden can afford to be without one or more of the Japanese cherries now grouped under P. serrulata and P. Lannesiana. Nothing in the genus can compare with them. Some of these can be purchased in a small state, and if so desired can be kept dwarf by pruning back after flowering. The sloe, or blackthorn, is sometimes a small tree also, but more often it is a shrub. Its double-flowered form, P. spinosa fl. pl., possesses all the pure whiteness of the wild plant, and this purity is similarly enhanced by the dark wood, but it lasts longer in beauty. Of truly shrubby character are P. triloba fl. pl. and P. japonica fl. pl., both with blush tinted double flowers very freely borne, the former early in April, the latter a few weeks later. P. triloba fl. pl. is an excellent shrub for a south wall where all its shoots should be pruned back close to the old wood as soon as the blossom has faded.

BERBERIS JAPONICA.
A beautiful shrub with fragrant flowers and striking foliage.

Two of the quinces have to be mentioned. The well known Cydonia japonica (especially the var. cardinalis) is always worth growing for its early blood red flowers, especially if a place on a wall can be given it not that it is tender, but

Digitized by Google

blooms better and earlier there. C. Maulei is dwarf, mostly under 3ft. in height, and its flowers are more orange-tinted or scarlet than the preceding. It flowers very freely if given a place in full sunshine. Osmanthus Delavayi is one of the very best of new Chinese shrubs, for it bears in April its pure fragrant flowers so abundantly as to envelop the shrub in white. Two shrubby amelanchiers are always worth their place: the American A. oblongifolia and the European A. vulgaris. The former increases by sucker growths from the base and in time forms a thicket of erect stems 6ft. high that carry numerous racemes of white flowers in April. A. vulgaris is even more beautiful, its pure white blossoms being the largest in the genus. Of the flowering currants I would recommend two: Ribes sanguineum, which has several forms, all good, but none perhaps better than the var. splendens with rich red flowers; and R. aureum with spicily fragrant, bright yellow blossom. Both flower in April, as does also a third species of Ribes (R. speciosum or fuchsioides) belonging to the gooseberry section; this is a singularly attractive shrub that produces its quite pendulous flowers in long rows beneath the branches; they are rich red with long exposed stamens and very much suggest small fuchsias. It is, however, better on a wall than in the open.

BARBERRIES.

Recent additions to the genus berberis have made it a very extensive one, and an ordinary garden can do no more than find room for a small section of it. B. stenophylla, a hybrid, is certainly indispensable; being, in the opinion of some people, the best of all evergreen shrubs. Forming a dark green, impenetrable bush, it is admirable as a wind-break and as a background, but although so dense in habit, it yet possesses great elegance by reason of the slender arching shoots, two feet or more long, it sends out each summer, which, the following April, are wreathed from end to end with golden yellow flowers. It is perfectly hardy and is worth planting in a group of a dozen or more plants.

B. Darwinii, one of the parents of stenophylla, is another fine evergreen of stiffer habit, its flowers rather larger, more orange in tint, and its leaves of the darkest glossiest green. B. Wilsonæ, one of the new Chinese introductions, is now well established in gardens and valued for its autumn beauty, made by clusters of coral red berries. It is, however, going to be surpassed by the hybrids or selected seedlings they have raised at Wisley. Two other Chinese species, distinct from any other, are B. verruculosa and B. candidula, evergreen bushes of neat habit with black-green shining leaves, glaucous underneath. A third is B. Gagnepainii, allied to the Himalayan B. Hookeri, but to be preferred to it. A dwarf seedling of B. stenophylla, called Irwinii, is remarkably profuse in bloom and is one of the very best of dwarf barberries.

Of deciduous barberries few, if any, surpass our native B. vulgaris either in beauty of flower or fruit, but it may perhaps be considered too common to be included among the elect. B. polyantha, from China, is most prolific in blossom and berry, perhaps, of all those coming from that country; B. Thunbergii from Japan may be grown for its lovely autumn tints; and B. aristata from the Himalaya for its fine foliage, flower-clusters and blue-white berries. For a small garden this last may be considered too vigorous; I have known it 15ft. to 20ft. in diameter.

PRUNUS JAPONICA FLORE PLENO WITH BLUSH FLOWERS.

The Mahonia group of barberries can be represented by three species: B. Aquifolium, so useful for furnishing semi-shaded places, and always pleasing for its lustrous, dark green foliage (purple-tinged in winter), its erect panicles of yellow blossom, and its plum-coloured berries. By the use of the knife it can be kept at any height between two and six feet, and altogether is a most useful, accommodating, as well as ornamental shrub, really essential to any garden. Another species would be B. pinnata (or fascicularis), a taller-growing sort reaching sometimes 15ft. to 20ft. in height, its foliage dull green, its flowers very fragrant. The third is B. japonica, of which Bealei, hyemalis and intermedia are forms, all very beautiful and fragrant in flower and striking in foliage, the large pinnate leaves, sometimes 1½ft. long, being made up of large, spiny-toothed black green leaflets.

While, when very old, the snowdrop or silver bell tree (Halesia carolina) justifies its popular name and is really a tree—Sargent describes it as sometimes 80ft. to 90ft. high—it is as a shrub we usually know and grow it. It is undoubtedly one of the most fascinating of them all, and it is difficult to conceive any shrub more beautiful than a bush crowded, as it always is in May, with the pure white, snowdrop-like blossoms.

COTONEASTERS AND PYRACANTHAS.

Our conception of cotoneaster, like that of berberis, has been much enlarged by recent exploration in China and from that country three species at least of the large number introduced must be included in the present enumeration. For these I would select C. Henryana, C. salicifolia, both evergreen and bearing red fruits and of charmingly graceful habit, and C. bullata, a deciduous species with enormous crops of brilliant red fruits. The best of the older species come from the Himalaya and none yet from any part of the world surpasses C. frigida, a deciduous red-fruited shrub of large size, which may, by keeping it to a single stem when young and pruning away lower branches, be made to form a small tree. At Aldenham and some other places is grown a specially fine form called Vicarii. Another Himalayan species, C. rotundifolia, semi-evergreen, should be grown for its red fruits, which persist on the branches till March, long after the others have shed them. C. microphylla with its close evergreen habit and depressed branches, its innumerable tiny glossy leaves, is admirable for clothing a steep bank or for planting at the top of a supporting wall over which it can be allowed to hang. C. horizontalis, a deciduous species, is, on the other hand, useful for planting at the base of such a wall, for, although naturally low and flat-growing, it will in such a position grow erect and flatten itself against it. Its fruit is red, and in autumn a proportion of its leaves dying off in orange and red add to its attractions.

PYRACANTHAS.—Their close relationship to the cotoneasters suggests mention of the pyracanthas here. P. coccinea, the old "fire-thorn," cultivated in England now for close on three centuries, is still the best. It is usually grown against a wall, for which it makes at all times a pleasing evergreen cover, but in autumn acquires much brilliance by its great crops of scarlet berries. It is perfectly hardy and equally beautiful in the open ground, where, nevertheless, it is rarely given a place. The newer kinds, Gibbsii and yunnanensis

Digitized by Google

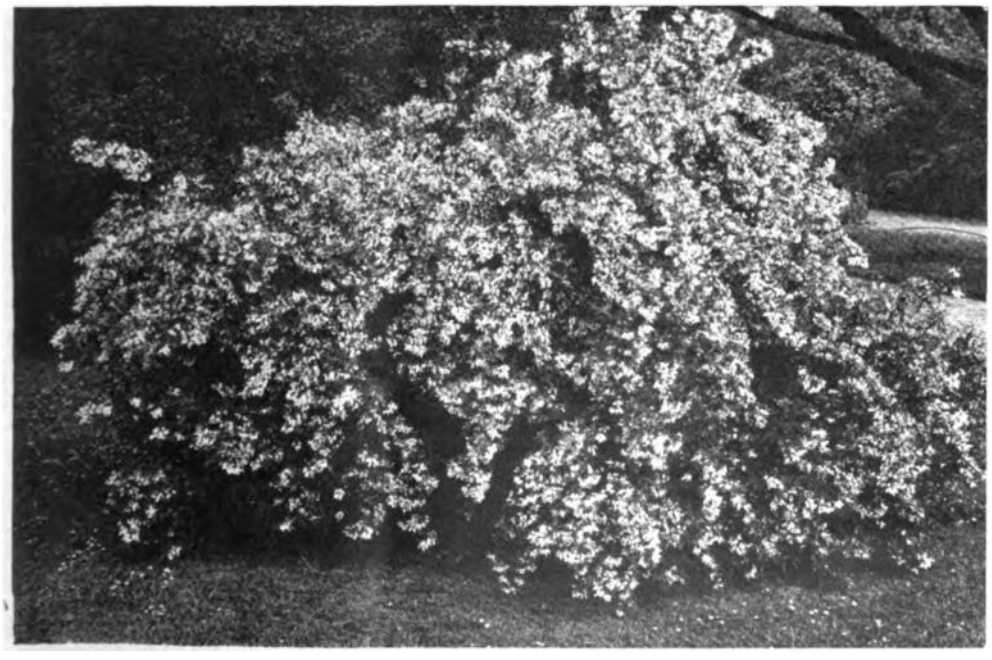
have bigger leaves and a more open habit, and retain their fruits longer than coccinea does through their not being so attractive to birds. P. Rogersiana is an elegant evergreen with smaller leaves than any other pyracanth, but I have not seen it as yet bearing fruit very freely.

There are, no doubt, some good things among the new dwarf thorns from America, but the genus crataegus as a whole is made up of trees. There is, however, a remarkable dwarf form of the common hawthorn, C. monogyna semperflorens, which flowers more or less continuously from June to August. It is so slow-growing that bushes twenty years old may be only 3ft. high.

THE DOUBLE BLACKTHORN, PRUNUS SPINOSA FLORE PLENO.

BROOMS, GORSE, ETC.

What we commonly term "brooms" are shrubs belonging to cytisus, genista and spartium, a large group confined, in nature, to Europe and North Africa, from which I select the following: Cytisus albus, the only really hardy white broom we have and a first-class shrub, either planted in a group or in a shrubbery among lowish evergreens, which it will soon overtop, yet not unduly rob or shade; C. purpureus, a dwarf purple-flowered kind very attractive in May and unique in colour among the brooms; C. kewensis, a low prostrate plant of hybrid origin with creamy yellow flowers and excellent for planting on a rocky ledge over which its branches may hang; C. scoparius Andreanus, the remarkable form of common broom with brownish crimson wing petals; C. nigricans, an elegant shrub with erect, slender racemes of yellow blossom terminating the shoots and opening from July onwards; Genista ætnensis, the Mount Etna broom, a tall shrub of thin, spare, yet not inelegant habit, with wiry leafless branches producing a wealth of golden yellow flowers in July; Genista virgata, also tall, but more bushy and leafy, and flowering in June and July; G. hispanica, one of the best of all shrubs for a warm, sunny, well drained spot, rarely exceeding 2ft. in height, close and dense in habit and, when in bloom, covered with its rich golden yellow flowers. Spartium junceum is worth growing for the lateness of its large yellow blossoms and the length of time during which they continue to expand—from late June to September. For a hot sunny slope or poor gravelly or sandy soil the double-flowered form of common gorse is very valuable.



SOPHORA VICIIFOLIA, A PLEASANT PLANT WITH BLUE WHITE PETALS AND A BLUE CALYX.

I may mention here a few other shrubs belonging to the same family as the brooms and gorse. Sophora viciifolia is one of the pleasantest of newer Chinese shrubs, bearing as it does in May and June a profusion of flowers with blue-white petals and a blue calyx, and being also particularly elegant in foliage and very hardy; Robinia hispida var. macrophylla (or inermis) is a shrub usually grafted on a short standard to make it a low tree and one of the loveliest of its tribe, with racemes of deep rosy flowers; Wistaria chinensis, although a climber not exceeded in vigour and size by any hardy one if subjected to no restraint, may yet, where there is no accommodation for it as a climber, be kept by pruning as a bush a few feet high, yielding every year a rich crop of blossom. Plants of this type are sent over from Japan in pots and frequently exhibited.

SOME HINTS FOR THE MANURING OF SOILS DURING SPRING

BY E. T. ELLIS.

IT is a generally accepted theory that manuring of soils can only profitably be done in the early autumn and winter, and that the spring, for some unexplainable reason, is an unsuitable period for carrying out the work. Nothing could be farther from the truth, because, if the question is carefully studied from the practical point of view and is followed up by careful experiments with suitable control plots, it will be found that better results are obtained by manuring in the spring than at almost any other period of the year.

A striking instance of this was afforded in a horticultural competition which was organised over a period of several years during the war. The best crops were obtained by manuring in the spring even on the heavy soils, and in almost every instance a poor and indifferent return was noted on ground that had had natural or artificial manures bestowed upon it in the autumn and winter—this being most pronounced in the case of the lighter sandy loams. I do not mean to imply that manure should never be used in the autumn or early winter, as, of course, there are certain artificial fertilisers which only dissolve very slowly in the soil—basic slag being probably the most important of these. If this and other comparatively inactive materials are applied to the land in the spring, no advantage is gained from their application, as the fertilising elements they contain have not yet come into solution. Further than that, in breaking up clay land for a vegetable garden for the first time, it is most advisable to apply manure in the autumn; the coarser and more strawy this is, the better. The object, however, is not to supply the soil with plant food, but to improve the mechanical condition of the soil, and, if the best results are to be obtained, further manure will have to be used the following spring.

With these and a few other exceptions of comparative unimportance it may be said that the best results are obtained by supplying plant-food shortly before the plants will require it.

It is doubtful, from experiments that have been made, whether the usual method of manuring soils, namely, to dig in organic manures before planting, is really the best way of going to work. Take potatoes, for instance: better results have been obtained by putting the manure in the trenches for these at planting time than by planting them on land which has been manured even as recently as February. It is recognised now, that the best crops of celery and leeks are obtained by growing them in generously manured trenches, which are only prepared a week or two before planting. Again, far better crops of peas and beans can be produced by sowing in trenches with a good thick layer of plant food at the bottom than in the case of plants grown on ground which has been dug over in the usual way. On sandy soils it is specially important to apply the manure without wastage. Thus, if any digging-in of manure is to be done in the spring let this be of the coarser material, strawy stable manure, half-rotted leaves and vegetable refuse in a semi-decomposed condition. Save the actual manure, to be used either at planting time or as a mulch. Better results will be obtained if this is done, and the cost of manuring will be considerably cut down.

Manures are generally considered in several different groups. Farmyard manure, for example, is, as a rule, the best for the stronger land, although rotted vegetable refuse often gives excellent results. Cow manure and pig manure that have mellowed down for a few months on the other hand are first-rate for the lighter loams and sandy soils. These two manures hold the water better than farmyard manure. Leaves seem to have great moisture-holding capacity and hence are valuable on light soils; while lawn mowings are a splendid medium either as a mulch or as a manure for these soils.

After natural manures, artificials must be considered, and it is, of course, now generally recognised that they are not substitutes for any of the materials already mentioned. Most artificials are stimulants of one kind or another, supplying either one distinct kind of plant food or several kinds. Nitrate of soda and sulphate of ammonia, containing as they do a comparatively high percentage of active nitrogen, stimulate leaf production, and are generally used during the growing season for this purpose. Potash manures, such as sulphate of potash, increase both the quality and the quantity of the crop. They appear to be specially necessary for root vegetables, such as parsnips, carrots, salsafy, beet-roots and potatoes. Superphosphate and other phosphatic fertilisers have a peculiar action which should be taken full advantage of. These fertilisers hasten the maturity of the crops, often to a surprising extent, rendering it possible to produce profitable crops late in the season before they are killed by frost.

With the exception of the first group, namely, the nitrogenous fertilisers, artificials are, as will be seen, unsuitable for application in the spring, and it is, therefore, not permissible to deal with them in greater detail in these notes. Sulphate of ammonia and nitrate of soda, however, must have a word or two more, as they often prove the means of saving a crop which might be ruined by an early attack by pests. If, on examination, it is found that one's rows of carrots and other similar root crops are not making the good progress they should, a light dusting of one of these fertilisers should be given along the rows—this to be either hoed or watered in. It is very seldom necessary to repeat this dressing, as its effect is generally all that is desired.

Between artificials and natural manures there is an intermediate class known as "animal products," for want of a better name. Horn dust, poultry manure, and ground fish meal are three of the principal ones, all of which are suitable for application during the spring if used carefully. Poultry manure contains a good deal of soluble nitrogen, and hence can be used for stimulating growth instead of nitrate of soda or sulphate of ammonia, when neither of these is available. Horn dust and fish manure, both of which are not very rapid in their action, may be used shortly before planting time, and are generally hoed into the surface at the rate of a few ounces per square yard. Both horn and ivory dust give extraordinarily good results with potatoes, but should not be used on land which has been liberally manured, or too much top growth will, generally, be obtained.

It is not, as a rule, my custom to refer to proprietary articles by name, but one so often receives enquiries as to a good substitute for farmyard manure where the latter is unobtainable, that I am going to do so with regard to it. Wakeley's Hop Manure is one of the very best substitutes I know of, and can be used with every confidence. It is, of course, much more concentrated than even the best farmyard manure, and hence much less need be used. In addition to this it is obtainable almost everywhere, and considering its food value is not at all expensive.

There are, as almost every reader knows, any number of patent fertilisers now on the market, which claim to suit every crop and to supply the needs of every garden. My own experience with very many of these has been very disappointing, and published analyses have shown that in the majority of instances they are sold at prices far exceeding their worth. One cannot, therefore, advise their application as a general rule, although it must be admitted that some of them are exceedingly convenient. If patent fertilisers are to be used at all, distinct brands for distinct flowers and vegetables should be obtained from firms of standing. It is far cheaper to make up one's own fertilisers, although it is more trouble to do so. Very little knowledge of chemistry is required, although many statements have been made to the contrary, and the results obtained from carefully prepared home-made mixtures are in nearly every case exceedingly good.

FORTHCOMING EVENTS.

GREENHOUSE FLOWERS AT VINCENT SQUARE

ALTHOUGH many of the flowers on view were normally hardy, it was really "Greenhouse Day" at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on February 12th, for most of them were grown under glass. Chief among the warm greenhouse flowers were the magnificent cyclamens from Reading; while the unheated greenhouse produced a great variety of alpines. Among the latter were many pans of excellent saxifrages, crocuses, bulbocodiums and other genera, shown by Mr. M. Fenwick, Stowe-on-the-Wold.

As we have already indicated, the outstanding exhibit was the collection of greenhouse cyclamens by Messrs. Sutton and Sons; its excellence may be gauged by the fact that a gold medal was awarded. A great number of plants, in distinct colour masses, were employed, and each was a specimen of the highest cultural skill, as well as illustrating a first-class strain of seeds.

In the Orchid Annexe, Mrs. O'Hea, Barford, Warwick, had an admirable exhibit of greenhouse cyclamens. The position did not permit of any novel manner of arrangement, but the many plants were of a high standard of excellence. These plants had stood the long journey from Warwick very well indeed. Along the end tabling Mrs. O'Hea's gardener had grouped many large plants of an excellent white variety, while the side tabling contained an equally extensive collection of these plants in mixed colours.

Another exhibit of much interest was that of hippeastrums, by Baron Schröder. There were twin groups of this well known greenhouse bulbous plant, edged with Lachenalia Nelsoni.

Cinerarias of the best Covent Garden Market type were staged in quantity by Messrs. Cragg, Harrison and Cragg. The Hounslow growers have for some time past paid special attention to blue and deep rose pink cinerarias of the stellata type, and have evolved splendid strains of both colours. Their plants are comparatively dwarf, sturdy, and bear large shapely heads of beautifully coloured flowers.

The graceful and highly decorative little varieties of Primula malacoides were again exhibited by Messrs. Carter and Co. in round baskets, and they also included good pot plants of hyacinths, tulips and crocuses, making a very artistic show.

A collection of greenhouse cyclamens was staged by the Hon. Vicary Gibbs. These were floriferous plants in 5in. pots.

Mr. L. R. Russell had a bright show of Azalea indica, with prunuses and Tillandsia Lindeni bearing its uncommon blue flowers. Messrs. Stuart Low and Co. showed mimosas, fibrous-rooted begonias and many perpetual-flowering carnations. Messrs. Allwood Brothers, Messrs. Keith Luxford and Co. and Mr. C. Engelmann contributed their customary collections of excellent carnations. The first named included especially good blooms of their new perpetual-flowering border varieties and a collection of Dianthus Allwoodii.

Many Freesias, yielding more fragrance than usual were associated with hyacinths and tulips in Messrs. R. and C. Cuthbert's exhibit. Violets of good quality were again shown by the Misses Allen-Brown and Miss Heathcote.

The quality of the pans of alpines exhibited by Mr. Mark Fenwick may be gauged by the fact that three of them received cards of cultural commendation. These were splendid examples of Saxifraga Irvingii, S. Faldonside and S. Burseriana Gloria. A large pot of the mealy Primula Winteri and a pan of Cyclamen Atkinsii rubra also evoked much admiration. Hardy cyclamens in many varieties were also shown by Messrs. Carter Page and Co.; Messrs. Waterer, Sons and Crisp, who included various saxifrages and irises; Messrs. M. Prichard and Son, in whose collection there were also some good blue primroses and many excellent saxifrages.

A GIANT WINTER ACONITE, ERANTHIS × TUBERGENII.

The earliest daffodils, shown by Messrs. Barr and Sons, seemed to fascinate many visitors with their tiny daintiness, and served to draw attention to the many other useful hardy border and alpine flowers, particularly to Petasites fragrans and some pure white hellebores. Among the many varieties of saxifrages, shown in small pots by Messrs. R. Tucker and Son there was an extra good batch of Saxifraga Brookside.

The large collection of polyanthuses and primroses contributed by Mr. G. W. Miller made a bright show, and he had some plants of the old-fashioned hepaticas. Primrose Pompadour along with Saxifraga Irvingii and S. Burseriana Gloria were prominently shown by Mr. F. J. Wood, while Mr. G. Reuthe included the uncommon Primula megasæfolia in his collection of shrubs and alpines.

Several nurserymen made low rockeries of moderate dimensions and utilised them to illustrate various plants. Messrs. William Cutbush and Sons had in their background a well grown little bush of Garrya elliptica bearing plenty of long catkins. Messrs. Pulham and Son, Messrs. Bakers Limited, Messrs. Skelton and Kirby, the Misses Hopkins and Messrs. J. Cheal and Sons also had informal rock gardens.

A number of shapely little conifers of the type valued for planting in the rock garden were contributed by Mr. G. G. Whitelegg and the Orpington Nurseries Company. A splendid bush of Berberis japonica Bealei bearing large numbers of its fragrant flowers was shown by the Hon. Vicary Gibbs, and Mr. Leonard Sutton sent from his private garden several plants of Primula calciphila with good spikes of lovely silvery lilac flowers.

Among the fruit exhibits the large pot plants of various citruses sent by Messrs. T. Rivers and Sons attracted much attention. These well fruited specimens included St. Michael's orange, large fruits of the citron of Paradise, Imperial lemon and several Japanese varieties of orange. A small collection of apples from Messrs. G. Bunyard and Co. were particularly firm and fresh, while most were of brilliant

MESSRS. RIVERS' ATTRACTIVE EXHIBIT OF CITRUSES.

Royal Horticultural Society Library

colour. The chief sorts were Sir John Thornycroft, Braddick's Nonpariel, Ballinora and Mannington Pearmain. Messrs. Shearns had quite a fruiterer's and florist's shop where they displayed high-class produce most attractively set out.

The only vegetables were one of the splendid collections which Messrs. Sutton and Sons set up so well. It contained practically every seasonable vegetable and salad of the highest merit. The most attractive seemed to be the Chinese rose-coloured radish, the variegated kales and the snow-white broccolis. The last named were compact heads of most tempting appearance, and the sorts were Sutton's Superb Early White, Christmas White and Winter Mammoth.

NEW AND RARE PLANTS.

COTONEASTER LACTEA.—In many ways this hardy evergreen shrub might be termed a more graceful Cotoneaster frigida bearing smaller, rounder and more brightly coloured berries. It is a useful addition to the berried shrubs in general use which continue to be ornamental throughout the whole of the winter. Award of merit. Shown by Mr. M. F. Stern.

CROCUS CHRYSANTHA BULLFINCH.—The flowers of this variety were somewhat squat, but this habit may be due to the cold weather. The broad cream-coloured segments make up a round flower which has a distinct orange centre and pale yellow filaments. Award of merit. Shown by Mr. E. A. Bowles.

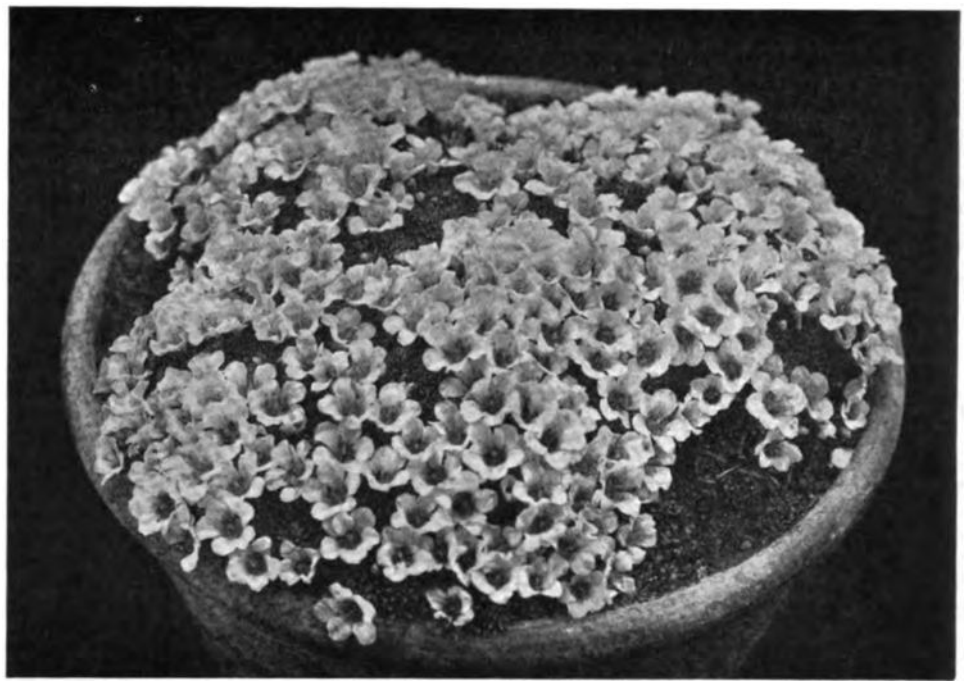
CROCUS C. MOONLIGHT.—The flowers of this variety were also short, but they were large and of a beautiful soft yellow colour stippled with brown on the back of each segment. Award of merit. Shown by Mr. E. A. Bowles.

CROCUS SIEBERI HUBERT EDELSTEN.—This is an exceedingly beautiful crocus and decidedly taller than the two previous varieties. The interior of the flower is lightly flushed, while the exterior is heavily stained with bright bluish purple. First-class certificate. Shown by Mr. E. A. Bowles.

ERANTHIS × TUBERGENII.—A giant among the winter aconites. The very large flowers are brightly coloured and in every way it is a highly desirable variety. Award of merit. Shown by Sir William Lawrence.

PRIMULA ROSSMARY BEAUTY.—This greenhouse primula is one of the nearest approaches to the old double white variety which thirty and more years ago was common in our greenhouses, though it now seems to have passed out of cultivation. The flowers were rather larger, not so double or so freely produced, but it is a very vigorous plant. Shown by Major-General Sir C. F. Hadden.

RHODODENDRON MUCRONULATUM.—Award of merit. Shown by the Director, Royal Botanic Gardens, Kew. [This is figured in our correspondence.—ED.]



A SPLENDID PAN OF SAXIFRAGA IRVINGII.

ORCHIDS.

AWARDS OF MERIT.

CYMBIDIUM CURLEW WESTONBIRT VAR. (Butterfly × Alexanderi), from Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt (gardener, Mr. H. G. Alexander). This plant carried an arching spike of seven flowers of greenish gold colour, the labellum having the side lobes and the apical area blotched with bright reddish crimson.

MILTONIA WILLIAM PITT VAR. THE PRINCE (Isabel Sander × Bleuana var. Reine Elizabeth), from Messrs. Charlesworth and Co., Haywards Heath. A handsome hybrid bearing a couple of large flowers, the segments flatly displayed and richly marked with crimson-rose.

ODONTOGLOSSUM XANTHIMUM (ardentissimum xanthotes × luteo-purpureum Vuylstekeanum), from Messrs. Charlesworth and Co. A very effective hybrid in which the semi-erect spike carried fifteen flowers, all the segments being marked with bright yellow blotches and spots.

CULTURAL COMMENDATIONS.

To Mr. Lewis Smith for a fine specimen of Cœlogyne cristata carrying no fewer than sixty-four sprays of flowers. This plant was one of fifteen almost similar specimens exhibited by Captain Maldwin Drummond, Cadland Park, Southampton, and to whom a silver-gilt Banksian medal was awarded.

To Mr. Macdonald, gardener to Sir George Kendrick, Whetstone, Edgbaston, Birmingham, for a superb example of Dendrobium Leeanum imported from Northern Australia.

THE QUESTION OF THE INBREEDING OF RHODODENDRONS

BY DR. R. J. D. GRAHAM.

THE extract which your correspondent quotes from Messrs. Standish and Noble's contribution to the Journal of the Horticultural Society for 1850 deals exclusively with hybrid rhododendrons. It is important to note that the observations were confined to hybrids and that the authors' subsequent remarks, including their warning, is derived from experience when inbreeding hybrids. They find on inbreeding a hybrid, caucasicum album, that in the third generation the progeny differ markedly both in stature and in ease of cultivation from the original hybrid. In particular, the inbred offspring are stated to lack constitution, and to this cause they attribute their failure to grow any of the plants to maturity. Judging from the fact that the inbred plants lived from two to eighteen months, may we not lay the reason for failure to faulty cultivation? One other important fact deserves notice. One good inbred plant, The Bride, resulted. What, then, is the evidence provided and the conclusion to be drawn from it? Surely, that inbreeding a hybrid results in a mixture of offspring which may differ both among themselves and from the parents. There was one plant that could be cultivated, The Bride, and many which could not be grown under existing conditions. Such occurrences happen daily in plant-breeding work. The reason for the phenomenon is that the original hybrid is a mixture of two species and their characters. Inbreed this hybrid and the mixture of characters asserts itself in various arrangements or shuffling of the characters, as in a whist-hand, among the offspring. So these experimenters found some of the progeny could be cultivated in the old way, others could not.

Often, in crossing peat-loving rhododendrons, the inbred offspring change in such a way that they become intolerant of peat. The direction of the change cannot be foretold, and must be determined for each individual by experiment. Further, each plant will not be alike. Some may take after the parents and prefer the old method of cultivation, and it was thus that Standish and Noble secured The Bride.

A further practical point may be mentioned here. The most difficult hybrids to raise and grow, frequently provide the best coloured and most

Digitized by Google

floriferous plants, thus repaying the extra attention demanded and expended on them. No textbook offers an explanation of this fact, and growers, according to their disposition, attribute it to contrariness of things in general or to the fact that virtue meets its own reward.

Turning now to the introduction of new species of rhododendrons from those floral paradises made familiar to many by the wonderful photographs and beautiful word pictures of Farrer, Wilson and Forrest, we have an entirely different proposition. Mark, in the first place, that we are dealing with species, not with hybrids. Let us, further, accept your correspondent's statement that the seed of these species is secured from naturally self-pollinated plants. These seeds will carry only the characters of the species, not a mixture of the characters of two species as in the hybrid, and, consequently, they will breed true to type. There is no mixture of characters to sort out in the first generation raised in this country, nor on inbreeding will there be any change, however long the process continues. Wheat has been inbred itself for countless generations and still remains the same. Rarely, a reshuffling of the characters may occur, and, possibly, this is one of the ways in which, during the ages, the different races of wheat have arisen.

Many of Forrest's new rhododendrons have been raised from seed in the Royal Botanic Garden, Edinburgh, and the fact that, when these flowered, they resembled closely the herbarium sheets is ground for confidence that the plants raised are true to type. These flowers have been inbred in Edinburgh and the progeny are as vigorous as their parents. There is nothing here to warrant the fears of your correspondent, nor is there in the history of the tried favourites among the species which have been in cultivation for over a century. Reference need only be directed to Moore's eulogy of ponticum, which has been grown from selfed seed since the latter half of the eighteenth century.

One further point perhaps deserves a word, namely, will the raising of a few plants in any way affect the issue? Many times the gathering of seed must be small and the number of plants raised in this country limited in number. In view of the above discussion the number of plants raised has, obviously, no bearing on the stability of the species either in nature or under cultivation. From a single seed of a species, or from a hundred seeds, the same general uniformity of character will result. Consider the introduction of an alien plant to a flora. In most cases the introduction is on a slender basis, but, provided the conditions are favourable, the alien has multiplied and has maintained its character. Consider the colonisation of an ocean island. The ocean-borne seeds arrived singly in many cases, certainly not in bushels, but the lonely arrival neither impaired the success nor the character of the species. Turn to de Vries and his work on mutations. His facts that the new forms arose in small numbers but were stable from the start may be accepted, whatever opinion one may hold regarding his deduction from the facts.

Even if, occasionally, seed of a natural hybrid, supposing such to occur, should find its way to this country in the collections, is there cause for despair? The betting, to follow your correspondent's phraseology, is evens on a good form resulting. There is an equal chance of the hybrid being good or bad. On inbreeding the hybrid again there is once more an equal chance of the progeny turning out well; but all the progeny demand equal attention, especially the weakly ones, if the best forms are to be secured. Forrest has remarked on one or two rhododendrons raised from seed sent by him to Edinburgh that he has not seen the plant in China. The origin of the new form is open to speculation. It may be a natural cross or it may have been a stray seed. The main point is that the plant is good.

To sum up, the evidence from growing rhododendrons shows that, as in the majority of species, inbreeding results in the production of as desirable forms from a horticultural viewpoint as was the parent. Inbreeding hybrids, on the contrary, results in the production of a multiplicity of forms, some of which are good, some not. The facts further show no loss of constitution as such, but indicate that the hybrid progeny when inbred require special cultivation, the nature of which can only be determined by experiment.

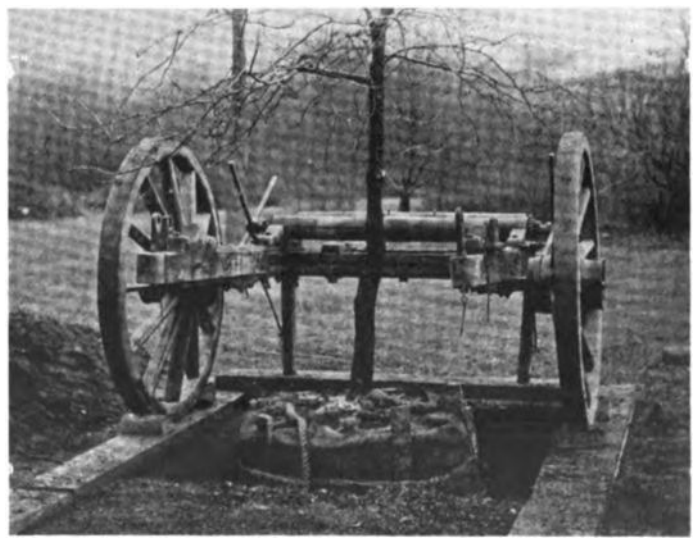
TRANSPLANTING TREES AND SHRUBS

BY A. OSBORN.

THE removal of trees and shrubs with soil attached to the roots is a common operation in the pleasure grounds and shrubbery borders. On the success or otherwise of this operation largely depends the future welfare of the tree or bush. Exactly how the mass of earth or ball of soil is dealt with depends on its size, and if large, the appliances and labour available for the work. In a general way the soil will vary from a few pounds in weight up to ten to fifteen hundredweights, or possibly a ton. It is only in exceptional cases that heavier masses of earth have to be dealt with.

To one of two reasons can usually be assigned the need for transplanting: (*a*) the tree or shrub has outgrown its position,

THE TREE ALREADY PREPARED FOR TRANS PLANTING TO ITS NEW QUARTERS.



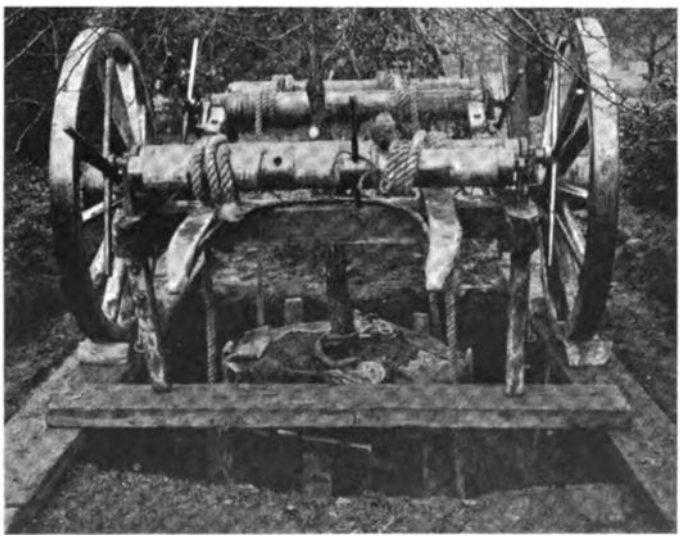
PLACING THE TRANSPLANTING MACHINE IN POSITION FOR LIFTING - THE FRONT ROLLERS REMOVED.

Digitized by Google

or (*b*) alterations in progress make it desirable to obtain an immediate effect, hence the moving of large specimens.

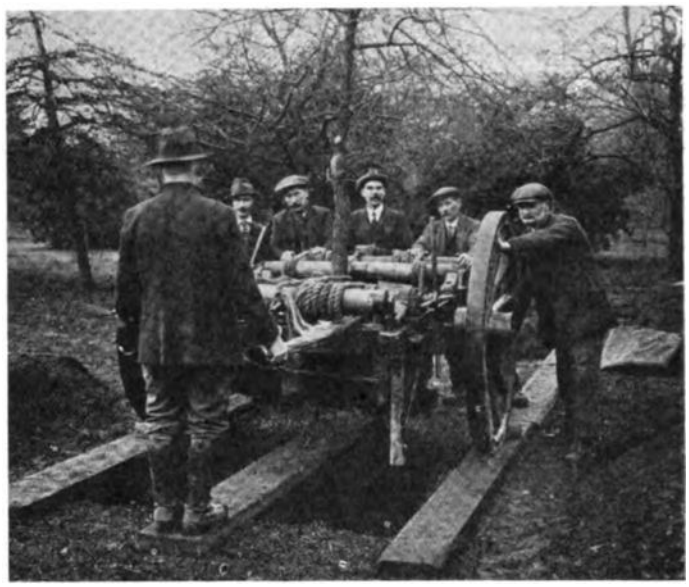
The best time for transplanting requires consideration, but when the specimens are moved with ample soil attached to the roots it gives the operator more latitude in his choice of time for the work, especially with evergreens. With deciduous plants it is desirable to limit removal between the falling of the leaves in autumn and about the end of March. There are exceptions: magnolias and hamamelis for example, transplant successfully during April and May. With evergreens, which are admittedly more difficult, it is a great help to be in a position to move them with ample soil and their root system practically intact. The normal, or shall we say the best, seasons for planting evergreen trees and shrubs are September or early October, and late April or May. With a machine such as the one illustrated, or some other method by which good balls of soil are transferred, such work can be safely carried on throughout the winter, and in exceptional circumstances during the summer. The rhododendron is perhaps the best example of all to quote as an easy evergreen to transplant with a good ball of soil in summer. We have, when occasion required, successfully moved plants in bud or flower with balls of earth weighing ten hundredweights and more. A very good example of moving hollies in midwinter successfully with a transplanting machine was seen at Kew during the winter of 1922–23. Of fifty specimens moved weighing from five to twenty hundredweights not one failed to grow.

Having decided on the plants for transplanting and selected their new stations, the first item of importance is to tie up the branches, if spreading. This will facilitate removal and prevent damage to the twigs during transport. The next business is to fix the size of the mass of earth to be moved with the plant. The hole illustrated is 6ft. square, the proposed ball is first marked out at 5ft. square. The intervening 1ft. of soil is then dug out all round to the depth of the roots, which will vary probably from 1ft. 6ins. to 2ft. 6ins. Next proceed to fork away the soil at the corners and gradually reduce the size required, making the ball round eventually, and if for a machine similar to the one illustrated it should not be more than 4ft. in diameter, this being the inside measurement of the frame. The careful forking away of the soil permits of the saving of the fibrous roots even beyond the actual diameter of the ball. Sometimes a thick root is unearthed, and this should be carefully cut off and the wound (cut surface) dressed with tar. Follow up this work by surrounding the ball with a thick canvas, fastening this round with two ropes,



ROPES FIXED IN POSITION READY FOR LIFTING.

one towards the top and the other round the bottom half. Between the canvas and ropes place five or six pieces of board, 2ins. to 3ins. wide, round the ball at equal distances to prevent the ropes cutting into the soil. To tighten up the ropes place a short stick in each and twist up, forming a tourniquet, holding firm by tying with string. The next process is to undermine the ball. When moderate in size a piece of stout canvas or matting may be used to transport it on. Gradually work the soil from beneath one side of the ball. When about halfway under, roll half of the canvas up and pull it under the centre of the ball. Next commence undermining the opposite side,



BRINGING THE MACHINE INTO POSITION OVER THE NEW PIT.

tip back the mass of soil on to the half of the open canvas and unroll the other half from the centre. Whether the plant is lifted out of the hole or drawn out on a plank depends on the weight. Details will vary considerably according to the actual work contemplated and the appliances available. I will explain the process necessary when moving trees and shrubs with the machine illustrated, leaving readers to vary the details to suit local conditions.

One item of importance is that the depth of the new hole should be several inches less than the old one to allow for wastage of soil from the bottom of the ball.

Several reasons can be advanced why good balls of soil should be moved instead of forking out the roots, as is done with nursery trees often larger than the one illustrated with the machine. Nursery trees are frequently transplanted, hence should have plenty of fibrous roots. To my knowledge the cratægus depicted in the illustration had not been moved for fifteen years. Thorns at this age are not among the easiest trees to transplant successfully. Many specimens we move with the machine would no doubt live if forked free from soil, but by using the machine the plants suffer little, if any, check, while without it they would take two or three years to recover. Commence by undermining the ball at the back and front until there is sufficient space to place two stout boards well under the ball and long enough to project several inches on either side. Round the ends strong ropes are passed connected with rollers on the framework of the machine above. Worked with cog-wheels, rollers and catches, the ball is gradually raised high enough in the transplanting machine to travel to the new position. Planks should be used for the wheels when moving the machine over lawns and cultivated ground. A small machine can be manipulated by four men, but for a machine lifting balls of soil weighing from seven or eight hundredweights upwards a minimum of six men is required, increased in proportion to the extra weight of the masses of earth to be transported.

Few private estates and public gardens have, perhaps, a sufficiently extensive collection of trees and shrubs to justify the purchase of a machine, but when extensive alterations are in progress the hiring of a machine will be found a great boon and add very considerably to the ultimate success in the growth of the specimens moved.

Failing a machine, two or three handy men with a few pieces of sacking or canvas, ropes, planks, levers, rollers, a jack and a low trolley can undertake a considerable amount of useful transplanting work.

CORRESPONDENCE

LIST OF PLANTS FROM WISLEY.

A VERY large number of your readers who are Fellows of the Royal Horticultural Society, will have just received the "List of plants and seeds for distribution," and will be making their hopeful choice of the many rare and beautiful things that it contains, but—should you consider the subject of sufficient general interest—may I be allowed to voice what I know to be the criticism of many of the Fellows?

Besides the desirable plants that are not, for one reason or another, easily obtainable, the list includes many others, such as Alyssum saxatile, Campanula persicifolia, Dianthus Mrs. Sinkins, Lupinus polyphyllus, Nepeta Mussini, etc., which can be had, mostly for sixpence apiece from any nurseryman, if they cannot be begged from a neighbour's garden, and moreover, are not very useful as single specimens. Could not such plants be omitted from the list without regret and their place taken by others, not necessarily of recent introduction, but such as are not easily procurable through the ordinary trade channels?

Very tentatively, the more tractable species of meconopsis, the species rosa and perhaps also the various species of crocus (that do so well at Wisley), might be suggested as examples, but no doubt Fellows of the Society would be willing to add others, perhaps more feasible and generally desired.—F. A. HAMPTON.

A NEW HEDGE PLANT.

THERE can be no doubt about the value of Lonicera nitida as a hedge plant. Apart from its utility, it is one of the most graceful shrubs that could be used for such purpose. Mr. H. Avray Tipping has done a good service in calling attention to this fine plant. Visitors to the Empire Exhibition at Wembley will see Lonicera nitida used as a hedge round the rose garden of Messrs. Dobbie and Co., Limited, of Edinburgh. An idea can be formed there of the grace and beauty of this lonicera when used as a garden hedge.—GEORGE M. TAYLOR, *Edinburgh*.

THE LABURNUM AND RABBITS.

THE statement made by Sir Herbert Maxwell (page 49) that rabbits devour young trees of laburnum and gnaw the bark of old trees is perfectly true. Early in the last century this was pointed out by J. C. Loudon, who stated that "hares and rabbits being remarkably fond of the bark of the laburnum, it has been suggested to sow laburnum seeds, in order to produce an undergrowth in plantations liable to be infested with these animals; for, though the plants are eaten to the ground every winter, yet they will spring up again the next season and thus yield a regular supply of winter's food for these kinds of game." This fact does not seem to have been acted upon to any great extent. On one game-preserving estate I have seen a wood underplanted with spruces, and not a head was left after the first snowstorm. In another rabbit warren I have seen the old beech trees painted with tar from the base for three feet upwards. The Scotch laburnum (Laburnum alpinum) used to be extensively grown in Scotland as timber for the turners and cabinet-makers before the art of staining wood was so well understood as at the present day. I have seen it in flower in the grounds of the Chelsea Hospital at the end of May, but that rarely happens, and even in that case the common laburnum maintained its priority and was quite out of bloom.—J. F.

RHODODENDRON MUCRONULATUM.

THIS is one of the most beautiful "heralds of spring" among the early-flowering rhododendrons. It is a close ally of R. dauricum, some authorities describing the plant as a variety of that species. For garden decoration R. mucronulatum is a superior plant, being more vigorous in growth, and having larger flowers. The leaves are less coriaceous than those of R. dauricum, up to about 3ins. long and 1¼ins. wide, approximately double the size of normal R. dauricum. The flowers are 1½ins. to 1⅝ins. in diameter.

R. mucronulatum is a native of Manchuria, North China, Korea and Japan. The first record of the plant is specimens collected by Dr. Kirilow near Peking about 1835. To Dr. Bretschneider belongs the credit of first introducing the plant to cultivation, he having sent seeds to the Arnold Arboretum in 1882. The group of plants illustrated are growing at Kew, and were raised from seeds received in 1904 from St. Petersburg (Petrograd) Botanic Gardens and Messrs. Regel and Kesselring in 1908. They range from 4ft. to 6ft. in height. In Korea where this species is very abundant, Mr. E. H. Wilson records plants 10ft. high. There is considerable variation in the colouring, from pale rosy-pink to a rich rosy-purple. A valuable character is that the flowers stand several degrees of frost. The ground was white with frost two mornings last week, but the flowers of R. mucronulatum suffered little if any damage. January and early February is the normal season of flowering. This year, in common with most early-flowering plants, it is ten days or a fortnight later than last year. There is scarcely need to suggest planting this useful rhododendron in a position sheltered from the east; the group illustrated is well protected from the east and south-east by a belt of arbutus.

RHODODENDRON MUCRONULATUM AT KEW. PHOTOGRAPHED FEB. 9.

While seeds form a ready method of propagation, the forms with rich rosy-purple blossoms are better increased by cuttings made of half-ripe shoots, which root readily about midsummer in a close propagating frame with slight bottom heat.

Exhibited by the Director, Royal Botanic Gardens, Kew, the Floral Committee gave this very useful early-flowering rhododendron an award of merit at the R.H.S. meeting on February 12th.—A. O.

WHY DELPHINIUMS?

THERE is an inexhaustible mine of legendary and historical buried treasure beneath many of our plant names. Those who have never undertaken any digging and delving below the surface have no idea of the interest and pleasure that such work provides. I wish every

Digitized by Google

had a sufficiency of books, or lived near enough to a large library, to undertake it in a serious way. Delphinium is a case in point. How came those beautiful blue blooms—which we know so well on their tall towering spikes, or when delicately poised on the low-branched stem of the lowly "Butterfly" race—to have had this name given them? There are two or three explanations abroad, the generally accepted one being that described by Gerard in his Herbal: "for (he says) the flowers, and especially before they be perfected, have a certain shewe and likeness of those Dolphines, which old pictures and armes of certaine ancient families, have expressed with a crooked or bending figure or shape; by which signe also the heavenly Dolphin is set foorth." They are going in very strongly for delphiniums in America. A quarterly (?) paper has been started at San Rafael, California, called *For Better Delphiniums*. The first number was issued in June, 1923, and the second in October, 1923. The delphinium is considered from a pictorial, mythological, historical, decorative, cultivational and imaginative point of view. It is all very interesting. We like to know something about what is taking place on the other side of the Atlantic; of the Vanderbilt hybrids; of Toole's Whites; of Hoodacres' splendid "Seedling 320"; then something about their ideals, "stately, slender, beautiful, with Pastel colouring"; then something about their trials and worries, and so on.

In the first number there is a long, unsigned "Ancient Note," in which the writer delves into the past and finds an entirely new derivation for the family name. Put shortly, it is that in Athens in ancient days there was a yearly festival of Apollo Delphinios, which took place at the time when the delphinium flowered, that is, on April 6th. It began by a procession, in which the Grecian maidens "adorned themselves with garlands of flowers of the favourite (deep blue) 'colour of the gods' (undoubtedly delphiniums at that period of the year) and with supplicating branches (olive) in their hands, formed a reverent and ceremonial procession to the temple 'Delphinion' in propitiation to Apollo on behalf of the seamen about to depart on the year trade cruises."

I have no book in my little library which throws any light upon the subject, but will not someone who knows Greece and who is well up in ancient Grecian history tell us if there is anything in the unknown writer's facts and deductions? The idea and derivation are new to me and may be new to others, and we would like information.

The only break-away from the orthodox explanations that I have found occurs in that curious book of quaint made-up moral tales which at once are explanatory fables and sermons, "The Compleat Florist," by the Sieur Louis Liger D'Auxerre (1706). My translation is bound up with the "Solitary Gardener" ("Le Jardinier Solitaire") which was "written in French by Francis Gentil . . . above thirty years Gardener to the Charter-House in Paris." This is the tale there: "Lark's Spur was a young Man of Portugal" who was keen on hunting and fishing. One day he fell in the sea and a dolphin saw him and rescued him. Some time after he saw that his friend the dolphin was very likely to be caught by fishermen in their nets. He managed to baulk their design, which so enraged them that they threw him into the sea. The dolphin when it saw his danger, popped him on its back and carried him to land. It was too late, the man was dead. He then asked Neptune, who in turn asked Flora, to turn him into a flower "which in some measure should resemble a dolphin." Hence delphinium.—JOSEPH JACOB.

NOTES FROM FRANCE.

OLD gardeners, in France, used to make great use of stevias. Now, however, as elsewhere, these plants seem to have dropped into unwarranted neglect.

They are mostly natives of Mexico and can be treated either as annuals or perennials. As annuals they come most readily from seed sown in gentle heat or in a cold frame in early spring and flower profusely the next summer and autumn. As perennials they require a slight shelter of dry material in severe winters and then make fine large bushes, flowering somewhat earlier than when grown from seed. All varieties are particularly useful for cutting purposes.

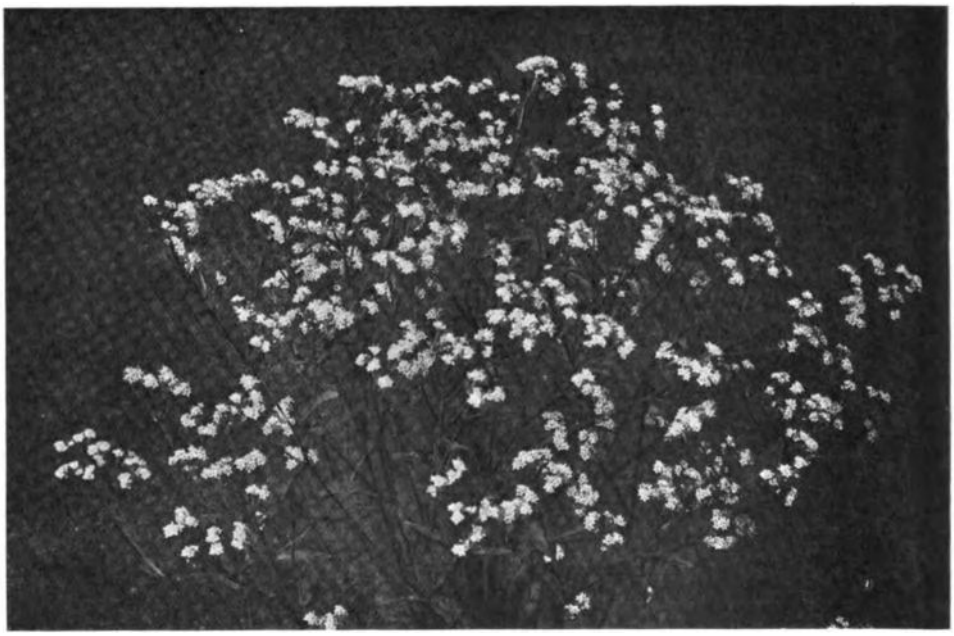
The growth of the plants is mostly rounded. The stems are erect or slightly curving on the sides, numerous and graceful, and bear, as the illustration shows, numerous small flowers, which continue over a very long period. These flowers are sweetly, though slightly scented. This perfume is, perhaps, not very appreciable at first, but if the flowers are cut and put into a room, the gentle, insinuating fragrance will be fully appreciated.

Two varieties of stevia are worth cultivating. Stevia purpurea, as its name implies, has purple lilac flowers. It grows to a height of about two feet. But the more interesting species is S. serrata, a white-flowered variety, reaching to about two feet. It is a strong grower and very free-flowering, invaluable for borders and decorative purposes of all kinds. In August and September, when the graceful and useful Gypsophila paniculata is over, the florist can use it as a substitute in all kinds of floral designs. As a flowering bush, it is a plant of perfect *tenue* that will give every satisfaction to anyone who tries it. It ought to be found in every garden, large or small.

Stevias grow in moderately rich soil. It is always advisable to give them plenty of room, in open and sunny positions.—CH. LERAY, *Paris*.

ASPARAGUS PLUMOSUS OUTDOORS

IN your issue dated February 9th, page 72, there is a letter on Asparagus plumosus as a window plant. My experience with it may be of interest to "C. T." and other readers.



STEVIA SERRATA A WHITE FLOWERED MEMBER OF THE COMPOSITÆ FROM MEXICO.

Some sixteen years ago I had a three-quarter lean-to house against a garden wall, part of which was kept as a stove and part as a greenhouse. In the warm division were several plants of Asparagus plumosus, and in the cooler some of A. Sprengeri. Having decided to discard artificial heat, the asparagus plants were bedded out at the foot of the wall. All were cut to the ground by frost, A. Sprengeri being killed. In the spring A. plumosus came up very strongly and did well year after year, the growths being often over 6ft. in height.

The only disadvantage caused by lack of heat being that each autumn very strong growths were pushed up which were unable to mature. I believe it would be worth while to try the experiment of growing this plant in a sheltered position out-of-doors, with some protection in winter.—R. C. BAYNE.

SOME OUT OF-THE WAY VEGETABLES

BY GEORGE GARNER.

IF cultivators who make a point of growing vegetables most commonly used for the table will add to their list some of the little known kinds, their interest and pleasure in vegetable cultivation will be increased.

There is, in the majority of gardens, small plots that should be devoted to the more rarely-grown kinds. But I would urge the necessity for good culture. The same high and generous cultivation should be applied to these as to the standard kinds, as without it success cannot be looked for.

THE CHINESE ARTICHOKE. — This vegetable will grow and increase freely in any ordinary soil, but the largest tubers are the result of good cultivation. The tubers are spiral in form, fully grown ones measuring about three inches in length and nearly one inch across the central or widest part. The tubers should be planted in March in well prepared soil moderately enriched with rotted manure. Plant them 1ft. apart in single rows, allowing 2ft. from row to row and cover with 3ins. of soil. The summer treatment is simple, the occasional hoeing of the soil between the rows being sufficient.

In October the tubers will be ready for cooking; they are best lifted from the ground as required. They should be boiled for twenty minutes, then fried in boiling fat till brown, carefully drained, and dusted with grated cheese. The correct name for this vegetable is Stachys tuberifera.

SPINACH BEET.—This is also called perpetual spinach. The roots are not used, but the leaves are available in late summer and early autumn. As fine, succulent leaves are the object of the cultivator the ground should be well enriched before the seeds are sown, first, early in March, then early in May, and about mid-July for the final sowing. The rows should be 1ft. apart and the resultant plants thinned to 9ins. asunder. When the leaves are fit to gather they should be cut off regularly, then more will grow and maintain a succession.

SILVER BEET.—A rich rooting-medium is essential to success and, in addition, some feeding will prove beneficial. Sow seeds in April in rows at least 18ins. apart and thin out the seedlings freely. The mid-rib is used, the leaves being pulled, not cut. The mid-ribs, carefully boiled, without soda in the water, are a very good substitute for asparagus.

CARDOON.—Rich soil is necessary and it should be deeply dug. In the case of light soils shallow trenches should be made, but level ground planting is best where heavy, retentive soils occur. Sow the seeds early in April in light soils and about the middle of the month in those of a clayey nature. The rows should be 3ft. distant and the seeds sown at 9ins. apart, finally to be thinned to 15ins. The summer treatment should be generous as regards feeding. The blanching process should begin at the end of August and may be carried out by wrapping stiff paper round each plant and earthing up. Straw or hay-bands serve the same purpose. The stalks of the inside leaves are the ones to use, either for stewing or for salads.

KOHL RABI.—Garden turnips are generally grown indifferently in some very dry soils. In such cases kohl rabi should be grown instead, as the roots of the later penetrate deeply into the soil. The cultivation is similar to that of the turnips; either the white, green or purple variety is of really good flavour. Although suitable for dry soils the plants grow splendidly in heavy ones. April is a good time in which to sow the seeds.

MAIZE.—The seeds in the form of green cobs are cooked and treated for table in the same manner as is asparagus. The essentials to success in its cultivation are a deeply dug, rich soil, and a sunny situation sheltered from strong winds. It is almost useless to attempt to grow fine plants and cobs in shallow soils and exposed places. In southern counties the seeds should be sown about the middle of April, and early in May in the northern. The rows should be 2ft. apart—6ins. more if there is room—and the seeds sown very thinly; the final thinning being done so as to leave the strongest plants not closer than 18ins. Water in dry weather and also apply a substantial mulch of littery manure.

SCORZONERA. — Cultivators possessing a poor shallow soil should not attempt to grow this vegetable, as poor specimens would result from ordinary treatment. Very fine roots may be grown in a deep loam. The best way to prepare the ground is to trench it two spits deep; add rotted manure to the lower portion of soil but none to the top. Sow the seeds in March and treat the resultant plants similarly to parsnips. Frequent surface hoeing during the summer months will help to stimulate growth.

The roots are ready for use early in the autumn. Before cooking, first place them in cold water for twenty minutes, squeeze in a few drops of lemon juice, then boil sufficiently and serve with white sauce. They are very palatable sliced when cold and fried in butter till nicely browned.

NEW ZEALAND SPINACH.—This is a true hot weather vegetable and may be grown very successfully in hot, light soils and in very warm positions. In the south sow the seeds early in May; in the north about May 20th. Deeply dig and enrich the soil with rotted manure. Where very clayey soil sobtain it is a good plan to use a peck or so of old potting or similar compost, to each plant to encourage early and free growth. Drop a few seeds 4ft. apart in the prepared soil and afterwards keep the ground clean. The habit of the plant is similar to that of the vegetable marrow; the leaves are almost of the same shape as those of the summer spinach, but much more succulent. Do not stop the rambling stems, but gather the largest leaves first from the base of each. Healthy plants grow rapidly and yield much produce.

SALADINGS.

In addition to those plants that are very substantial in the salad bowl, such, for example, as the tomato and lettuce, there are many more that are much appreciated when used simply to impart some variety to the flavour. Salads, in themselves, on account of the salts they contain, are very beneficial to all who eat them.

CORN SALAD.—Another name for this plant is Lamb's lettuce, and on account of its rapid growth in spring is valuable as a substitute for lettuce at that period. Plants may be grown in the summer, but the most satisfactory plan is to sow seeds in August in rather dry soil and to winter the plants after thinning them out to 9ins. apart and so have good leaves available early in the New Year.

CURLED CHERVIL.—Sow the seeds in spring in rich soil, not large breadths, but small ones. Make a sowing about every six weeks. The soil should be deeply dug and the plants watered well in dry weather. Thin out the seedlings as strong plants do not "bolt" to seed as quickly as overcrowded ones.

DANDELION.—When properly grown and blanched this salad plant is much appreciated. The soil intended for the crop should not be manured and the position should be a dry, sunny one. The young plants are difficult to transplant successfully so it is best to sow sufficient seeds in May in rows 18ins. apart and to thin out the resultant seedlings to 1ft. in the rows. The object is to secure strong roots and, like other root crops, summer cleanliness and frequent hoeing of the soil has a beneficial effect. In the autumn and winter the roots should be very carefully lifted—not pulled up—packed fairly closely together in deep boxes or pots, surrounded with fine soil and watered. Any cellar or darkened shed will answer the purpose for blanching. From February onwards, blanching may be done by covering the plants, where grown, with dry straw. In all cases the blanching should be well done.

NASTURTIUM.—The flowers of these plants are sometimes added to the other contents of the salad bowl, and the pods pickled like those of the radish.

SALSAFY.—A deep soil inclined to lightness is an ideal one for this crop. The ground should be well prepared before the seeds are sown so that there will not be any necessity for more disturbance of it in the summer time than that entailed in the destruction of weeds by hoeing. Manure the lower portion of soil, not the top. Sow the seeds in April in drills 18ins. apart and thin the seedlings to 1ft. distant. The roots, if lifted in November and December, should be stored in sand. The tender shoots, or chards, produced in spring from plants left in the ground throughout the winter are very nice and are cooked in the same way as asparagus.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Potatoes.—In sheltered gardens a small quantity of tubers may be planted which will, if all goes well, furnish an early supply. Choose mild weather for the operation and when the soil is fairly dry on the surface. Shallow trenches should be prepared 18ins. apart, and the tubers set out at intervals of 1ft. Cover them with old potting compost, leaf-mould, or any light dry soil that is available. An early variety should be selected and, if possible, the tubers sprouted.

Mushrooms.—Continue to collect material for another bed, and when sufficient is at hand it should be made up. The horse-droppings will need turning a few times to allow rank steam to escape; at the same time, remove all the straw possible. The bed should be from 18ins. to 2ft. deep at the back and about 15ins. at the front. Tread the manure firmly, and when the bed reaches a temperature of 80° Fahr. or so it may be spawned. The brick of spawn should be broken into pieces about the size of a hen's egg and placed in the manure at intervals of 9ins. or 10ins. It should be only just covered. A thin layer of sifted loam should be spread over the bed and made firm with the back of a spade. An old shed or stable where it is dark will be found suitable for mushrooms. During cold weather a load or two of long manure, which will be similar to a hot-bed, will maintain the required temperature of 60° Fahr. When water is required it should be warm and applied through a fine rose.

Winter Onions may now be planted out in lines 1ft. apart. See that the plants are made firm and not planted too deeply. Onions pay for generous treatment, so they should be given a well prepared piece of the garden. A dressing of soot on the surface will prevent worms from pulling the plants into the soil, and it will also be beneficial to the crop.

Jerusalem Artichokes should be planted at once in a well tilled plot, as they enjoy a long season of growth. They should be set in rows 2ft. to 3ft. apart and 1ft. between the plants.

THE FLOWER GARDEN.

Preparations for Bedding.—Having ascertained the number of plants required for the various beds, the work of propagation may be proceeded with. Heliotrope will root freely if given slight bottom heat, and the same remark applies to iresine, marguerites, salvias, ageratum and similar plants. Pelargoniums, if the stock is low, can also be increased by cuttings, and the rooted plants should be potted off singly, giving them every encouragement to make large healthy plants. The double forms of the blue lobelia can also be propagated by cuttings and division of the stock plants. Full use ought to be made of the propagating frames during the next few weeks.

THE HARDY FRUIT GARDEN.

General Work.—The propagation of bush fruit by means of cuttings should be completed at an early date, and the pruning of all kinds of trees brought to a conclusion. Directly the work is completed, collect the prunings and burn them, carefully going over the fruit quarters and digging up all deep-rooting weeds, such as dandelions, etc. Afterwards lightly fork between the trees and bushes, and make the whole as tidy as possible. Young trees in grass orchards may also receive attention.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Carrots.—For sowing now, on the open border early varieties should be chosen, such as French Scarlet Horn or Early Scarlet Horn. Select a sheltered position on a south border, and take out rows 12ins. apart and 6ins. deep, with a spade. Fill the rows with sand before sowing the seed. By doing this a crop of nice clean roots should be obtained.

Celery.—Where quantities of this vegetable are in demand, the main sowing should be made in boxes filled with prepared soil, and germinated in heat.

French Beans.—To have a prolonged supply of this vegetable it is necessary to grow one or more batches of plants under glass. Prepare 8in. pots by crocking and filling them with good potting soil. Five or six plants are quite sufficient to grow in each pot, but it is better to insert rather more than that number of seeds in each pot. Set the pots in a warm temperature. I have found Canadian Wonder a very good cropping variety.

Jerusalem Artichokes.—This vegetable is a species of sunflower, and sends up tall stems from the edible tubers; on this account the plants are often used as a screen or shelter for other plants. But, like most vegetables, they respond to good treatment. The two varieties in cultivation are known by their tubers, which are purple and white. These should be planted 6ins. deep and 12ins. apart in rows 2½ft. distant.

Peas.—Further sowings of the Pilot and Gradus varieties should be made.

Potatoes.—On a border with a south exposure and fairly light soil, rows should be taken out 2ft. apart and the sets—or tubers—placed in these 9ins. distant from each other. Leave all growths on the sets, as the young haulms when above ground are sometimes damaged by frosts. We grow first early potatoes between the lines of early peas. In the past we have found Epicure a reliable variety, and one from which tubers may be obtained early in June.

Turnips.—A few drills should be drawn out 1in. or so deep and 1ft. apart—on the same border as used for early carrots—and seed of Early White Dutch or Extra Early Milan sown therein.

THE FLOWER GARDEN.

Chrysanthemums.—These gay and decorative border plants repay, by their beauty and wealth of bloom, all who grow them. Where old shoots have been wintered under glass, cuttings from these should now be obtainable. These should be detached and dibbled into boxes filled with sandy soil made firm. Place the boxes in a moderate temperature and well water. Keep the cuttings shaded from bright sunshine until rooted.

Commelina cœlestis.—Blue-flowered plants are usually much appreciated, and the commelina, although not gaudy, is attractive, with its blue flowers and somewhat peculiar growth formation. If roots were kept throughout the winter they should be brought on in moderate warmth; seed, too, may be sown in heat, and the plants, when large enough, set out in the open when all danger from frost has gone. There is also a white-flowered variety of this plant.

Sweet Peas.—Plants raised from seed sown in boxes last autumn should be set out on a sunny border. After planting, dust the ground along each line of plants with lime or soot; this will help to ward off slugs.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Gebera Jamesoni, and the many beautiful hybrids and varieties originating from this species, are worthy of more general cultivation by every lover of choice plants. In the south and west, gerberas may be successfully grown in dry, warm borders at the foot of a wall, with a sunny exposure, but over the greater part of the country they must be regarded as greenhouse plants. A stock of plants is easily raised from seed sown at this time, and with good cultivation they should produce a few flowers during the autumn. However, they should be at their best the second and third year from seed. In fact, when planted out they last for quite a number of years. Their successful cultivation in pots is by no means easy. To grow them well they require large pots; pots out of all proportion to the size of the plants. Thus I advise anyone who wishes to grow them in quantity for a supply of cut flowers, to plant them out in a raised bed in a sunny, airy greenhouse. The bed should be well drained and filled with about 15ins. of sandy loam, to which a little fibrous peat or good flaky leaf-soil may be added, with enough clean coarse sand or old mortar rubble to keep the whole open and porous. Under such conditions they should grow and flower freely. White fly proves rather troublesome, and should be kept in check by some approved remedy. Aphis sometimes infests the flowers, but frequent light fumigations should prevent any trouble from this pest.

Ericas and other Hard-Wooded Plants. Where cuttings of these plants were put in last August and September, many of them should now be well rooted and ready for potting off. This should be very carefully done as their fine roots are so easily injured. The compost at this stage should consist of fine sandy peat, while thumb pots should be large enough for them at this time.

Forcing Plants.—Wistarias should never be given high temperatures or else the buds will drop. Viburnum Carlesii is best brought on in an ordinary greenhouse temperature. Crocuses should be grown perfectly cool or else they go blind. Most varieties of narcissi used for this purpose force readily, but tulips are by no means so easily managed, especially the Darwin varieties. Failure is generally due to using unsuitable varieties, and by placing them in too high a temperature. The large-flowered varieties of the Ghent azaleas are very popular for forcing. Their flowers, however, drop off very quickly, but this fault can readily be overcome by placing a drop of floral gum at the base of each flower. By this means it is surprising how long the flowers remain fresh on the plants. While most shrubby plants may be lifted from the open ground during the autumn and potted up, with more or less successful results, it is always best if such plants are pot grown. For example, a pot grown lilac will keep fresh for several weeks in a cool conservatory, while one lifted from the open ground will only last about a week. Plants, like rhododendrons, that have a fine root system may be lifted from the ground at any time and be successfully forced; varieties that flower early naturally being best for this purpose.

Jacaranda ovalifolia (syn. J. mimosæfolia).—This plant with its light elegant foliage is very useful for decorative work, and for grouping with other plants in the conservatory. It is easily raised from seed sown at this time in a warm house. Although generally used in the young state for decorative work it is worth planting out in a bed in the conservatory in hopes that it may produce its beautiful blue flowers.

BARRS' BEAUTIFUL LILIES, GLADIOLI, CANNAS, DAHLIAS, MONTBRETIAS, TIGRIDIAS, TUBEROSES, etc., for February to April planting. Descriptive Catalogue free.—BARR AND SONS, King Street, Covent Garden, London, W.C.2.

FIDLER'S NEW ILLUSTRATED GARDEN SEED GUIDE AND CATALOGUE FOR 1924 IS NOW READY, and a copy will be sent post free to any address on receipt of postcard.—Write at once to FIDLER AND SONS, Royal Berkshire Seed Stores, Reading.

BUY GARDEN FRAMES THAT LAST.—Flattering testimony is constantly being received concerning B. and P. high-grade Frames. They are a sound investment and last a lifetime. Prices from £2 19s. Carriage paid. Ask for catalogue.—G.116, BOULTON AND PAUL, LIMITED, Norwich.

SEWAGE DISPOSAL FOR COUNTRY HOUSES.—No emptying of cesspools; a perfect fertiliser; no solids; no open filters; perfectly automatic; everything underground. State particulars.—WILLIAM BEATTIE, 8, Lower Grosvenor Place, Westminster.

PERRY'S NEW SEED CATALOGUE now ready. Perry's new catalogue of Gladiolus, Montbretias, Lilies, now ready.—PERRY'S HARDY PLANT FARM, Enfield.

"BEAUTIFUL LILIES" for February till April planting. Speciosum rubrum (ex. large), 1/6 each, 16/- doz.; speciosum album (ex. large), 1/6 each, 16/- doz.; auratum (ex. large), 1/9 each, 18/- doz.; longiflorum giganteum, 9d. each, 8/- doz.; sulfurgale, the wonderful new hybrid, 3/6 each.—REUTHE, Keston, Kent.

HARDY ORCHIDS.—12 Hardy Terrestrial Orchids, all different, named, 10/- post free for c.w.o. List free. New Alpine Catalogue also ready.—BOWELL & SKARRATT, Nurseries, Cheltenham.

WE ARE SHORTLY ISSUING A NEW Catalogue of Hardy Plants (Speciality Rock and Herbaceous Plants), including many new and rare varieties. May we send you a copy?—B. TUCKER AND SONS, Brookside Nurseries, Headington, Oxford.

WATTS' GIANT POLYANTHS - PRIM-ROSES. First-class Certificate National Primula Society. Yellow, Dark or Mixed Seed, 1/- and 2/6 packet.—THE WELSH BULB FIELDS, ST. ASAPH.

ROCK PLANTS, best varieties, inexpensive. List free.—MARION GLENDINNING, Fardross, Clogher, Ireland.

EVENTUALLY, WHY NOT NOW?—You will find for quality and value it will pay you to send for my Lists of Annuals and Perennials and buy from REV. C. BARNES, F.R.H.S., The Garden, Worksop.

BOOKS.—Mr. E. T. Ellis, Horticultural Writer and Editor, The Firs, Wye, Kent, has for disposal about 100 Gardening Books, covering most branches. List post free. State wants. Mention THE GARDEN.

DELIGHTFUL for Border or Rockery, Cheiranthus Allioni, rich orange masses, strong plants, 4/- doz., post free.—MILNE, South Darley, Matlock.

WANTED, several thousands best quality young Hazel Plants about 2ft. high, bushy, with several shoots. —Write G. W. CHAPMAN, The Oaks, Tadworth, Surrey.

18 FOR 10/6, Car. paid. English-grown Roses. Ellison's Pedigree Seeds. Prices most reasonable. Government germination guaranteed; therefore grow ELLISON'S PEDIGREE SEEDS. When doing so you are buying from a firm established 1890. Regular exhibitor at the principal shows; 46 Gold Medals awarded. 64 page Catalogue free. SEEDS, BULBS, ROSES, FRUITS, FERTILISERS. Shallots, 14lb., 7/- car. paid. G. & A. Fertiliser, 5/- cwt. Broad-leaf Privet, 15in., 12/- 100. Scotch Seed Potatoes, 13/9 cwt. — ELLISON'S, Seedsmen, West Bromwich.

SUTTON'S LILIUM AURATUM

(The Golden-rayed Lily of Japan).

Undoubtedly the finest of Lilies, whether we regard its size, its sweetness, or its exquisite arrangement of colour.

We are able to offer the choicest bulbs at lowest prices.

Extra large bulbs, each 2/6; per dozen, 27/6.

Selected bulbs, each 2/-; per dozen, 21/-.

SUTTON & SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT A KELWAY Colour Border to include our world-renowned Specialities—Pæonies, Delphiniums, Pyrethrums, Gaillardias, Phloxes, etc., etc. Borders of any kind can be arranged. Write us with your ideas and we will quote. Please give this attention NOW.—KELWAY AND SON, The Royal Horticulturists, Langport, Somerset.

NOW IS THE TIME TO PLANT KELWAY'S

DOBBIE'S 1924 CATALOGUE AND GUIDE TO GARDENING: 130 Pages, over 160 Illustrations. Send to-day, mentioning "THE GARDEN," and you shall have a Free Copy per return post.—DOBBIE & CO. LIMITED, Seedsmen to H.M. The King, Edinburgh.

BATH'S SELECT SEEDS & PLANTS. New Illustrated Catalogue of Choice Vegetable and Flower Seeds and Plants is now ready and will be sent post free on application. Special terms to allotment societies. Dept. E, R. H. BATH, LIMITED, The Floral Farms, Wisbech.

RARE PRIMULA AND ALPINE SEEDS from one of the largest collections sold cheap. Lists free.—REV. J. F. ANDERSON, Glenn Hall, Leicester.

WELLS' CHRYSANTHEMUM CATALOGUE now ready. Post free upon application. W. WELLS AND CO., Merstham, Surrey.

LOWE AND GIBSON for choice Gladioli, Border Carnations and Bearded Irises. Our seed leaflet for 1924 just to hand and may be had on application. Pedigree seed of Gladioli, Delphiniums and Border Carnations only. New Gladiolus list.—Oakfield Gardens, Crawley Down, Sussex.

BARNARDS, LTD., NORWICH, for Garden Requisites of all kinds.

BARGAINS IN GARDEN WIRE ! ! !—Government Field Telegraph Cable, cost £35 per mile; our price less than a twentieth!! Great for training fruit trees, greenhouses, pergolas, arches, tomatoes, hops, beans, peas, loguns, chrysanths; tying, fencing, etc. Steel stranded; waterproof covered and several thicknesses, from 19/6 per mile (full 1,760 yds.). Small lots supplied. Secure a supply in readiness. Postcard to-day for free samples, and list of 300 bargains post free.—GREEN'S BARGAIN STORES, 468, Seymour Road, Lytham.

WHITE FOXGLOVES, nice plants, 5/- doz., post free.—MILNE, South Darley, Matlock.

CHOICE ALPINES.—A large stock of good things to offer. Send for fully descriptive catalogue containing much information about soil and suitable positions for planting. Special offer of Aubretias. 6 varieties for 3/6, carriage paid. Pleased to book for delivery now or later. Further offers of other species in preceding and succeeding issues.—THE BARNHAM NURSERIES, LIMITED, Barnham, Sussex.

TANNED GARDEN NETTING, small mesh, 45yds. by 1yd., 3/3; 45yds. by 2yds., 6/6; 45yds. by 3yds., 9/9. Extra stout Netting for gardens and tennis boundaries, 25yds. by 8yds., 50yds. by 4yds. and 100yds. by 2yds., 18/- each. All carriage paid. Tennis and Cricket Nets and equipment a speciality. Nets redressed and repaired immediately. Sports lists on application.—GALLOP, Net Manufacturer, Hastings

GREENHOUSE PAINTING AND GLAZING. —"Vitrolite," superior to White Lead Paint, 18/6 per gallon, cans extra. "Plastine," the Imperishable Putty, 32/- per cwt., kegs extra; 7lb. tins, 4/- post free; 14lb. tins, 5/6 each, carriage extra tins free.—Full particulars from W. CARSON AND SON, Grove Works, Battersea, S.W.11.

The Rose— the most beautiful flower

in all the world, with the delicate softness and symmetry of its petals, its gorgeous hues and tones—creates an atmosphere of delightful rest and seclusion in any garden.

The King's Acre Nurseries—famous since 1785 for the stamina and vigour of its roses—have hardy and reliable

STANDARDS, BUSHES and RAMBLERS

in a wonderful, almost endless, variety, which they are offering at prices considered by experts and amateurs to be beyond competition.

PEONIES

ON the opposite page will be found an article by Mrs. Edward Harding on the subject of Peonies in the British Isles. Mrs. Harding is one of the greatest of experts on this fascinating subject. In the United States, where she lives, she has made practically a life's work of the introduction and the popularisation of the peony. As she also has an extensive knowledge of English gardens, she writes with authority on the question of their cultivation on this side of the water.

On reading her article it will be noticed that she emphasises one point: surprise that the peony is not more popular in the British Isles. This is true, and all the more remarkable owing to the constant mention of the peony in old MSS. and printed herbals, which prove over and over again that it was in common cultivation in this country in very early times. Miss Rohde in her book on "The Old English Herbals," says that the peony throughout the Middle Ages was held in high esteem for its protective powers, and that even during the closing years of the last century country folk hung beads of its roots round children's necks. Gerard also states that "The black grains to the number of fifteene taken in wine or mead is a speciall remedie for those that are troubled in the night with the disease called the Night Mare, which is as though a heavy burthen were laid upon them and they oppressed therewith, as if they were overcome with their enemies, or overprest with some great weight or burth and they are also good against melancholie dreams." Probal peonies were only grown for their supposed magical and me cinal properties, but many of our finest garden plants start from the same humble beginnings.

There are several other curious points about this lack interest. Peonies may be classed as large herbaceous plan along with delphiniums, gladioli and hollyhocks, and ov all these plants there is great enthusiasm in this countr New delphiniums of the most brilliant shades come alo with amazing rapidity; gladioli are much sought after f delicacy of colour; hollyhocks increase in stature and br liance every year. Yet if peonies are mentioned, it is on to say that there are a few in the garden, usually not named varieties, and that they make a fair show; but that all; there is little or no enthusiasm.

Apparently there is no reason for it; they are perfect hardy and certainly as easy to cultivate in this country as the United States and Canada, where they are among the mo popular of garden plants. For richness of growth and conto and for magnificence of colouring there are few plants to equ them.

It is rather sad that there is little literature in the Britis Isles on the subject of peonies, and that we have to go America for our information.

Mrs. Harding has written an admirable book on th subject—"Peonies in the Little Garden," published b the *Atlantic Monthly* Press, Boston. Although short— it is only ninety pages—it covers the subject from A to Z It goes into varieties, French, American, and English, locatio and soil, planting and fertilising, root division and seedling and peony diseases. She knows how to temper her enthusiasm and her criticisms of different varieties are remarkably fran and just. Even without illustrations it is easy to judge c the value of a particular variety from her descriptions. Th only criticism that can be made of her book is that it doe not go far enough. There are no descriptions of any of th peony species which interest many people and, althoug not so brilliant in colouring, are often more graceful in growth She also leaves out mention of tree peonies, which appear t be more popular in this country than in America. As ha already been announced in the horticultural Press and in th R.H.S. notices, Mrs. Harding is presenting a silver cup durin 1924, 1925 and 1926 for the best exhibit by an amateur o three flowers each of six varieties of peony. This year th award will be given on June 11th. The conditions are no severe, and it is hoped that many amateurs will exhibit. A any rate, we have to thank Mrs. Harding for a much-needed fillip to the cultivation of the peony in the British Isles.

THE NEXT IS OUR SPRING NUMBER
AND AMONG ITS CONTENTS WILL BE:

GLADIOLI, by Major Churcher.

NEW AND RARE CONIFERS, by E. H. Wilson of the Arnold Arboretum.

SWEET PEA CULTURE, by Donald Allan.

HERBACEOUS PEONIES IN ENGLISH GARDENS

BY MRS. EDWARD HARDING.
AUTHOR OF "THE BOOK OF THE PEONY" AND "PEONIES IN THE LITTLE GARDEN."

"CANON ELLACOMBE held that no garden could flourish which was not constantly giving." The quotation is from the delightful memoir of Henry Nicholson Ellacombe, published by *Country Life* in 1919. Although in this particular instance Canon Ellacombe clearly had in mind the gift of plants, he undoubtedly meant also the gift and exchange of thoughts and experience. "Gladly wolde he lerne, and gladly teche." His whole gardening life was an example of both.

To these ideas every true gardener will cordially subscribe. Despite governmental quarantines and official difficulties imposed these days upon the import and export of plants, there are, happily, no limitations upon the exchange of reports and ideas.

As each of us could ill spare the wealth of help and inspiration contained in the world's horticultural magazines, so, instinctively, each one of us searches therein for the record of his own especial favourites—their behaviour, their successes, and their failures—in other gardens than his own. On looking over the index of THE GARDEN for last year I find that only one article on the peony was printed. That article was on the tree peony.

It has always surprised and puzzled me that the beautiful modern hybrids of P. albiflora are so little grown in the land of famous gardens. The marvels developed by the French growers are at England's door, to be secured with far greater ease of transportation, and because of that and various other reasons, at a far more modest price than we have to pay for them in America.

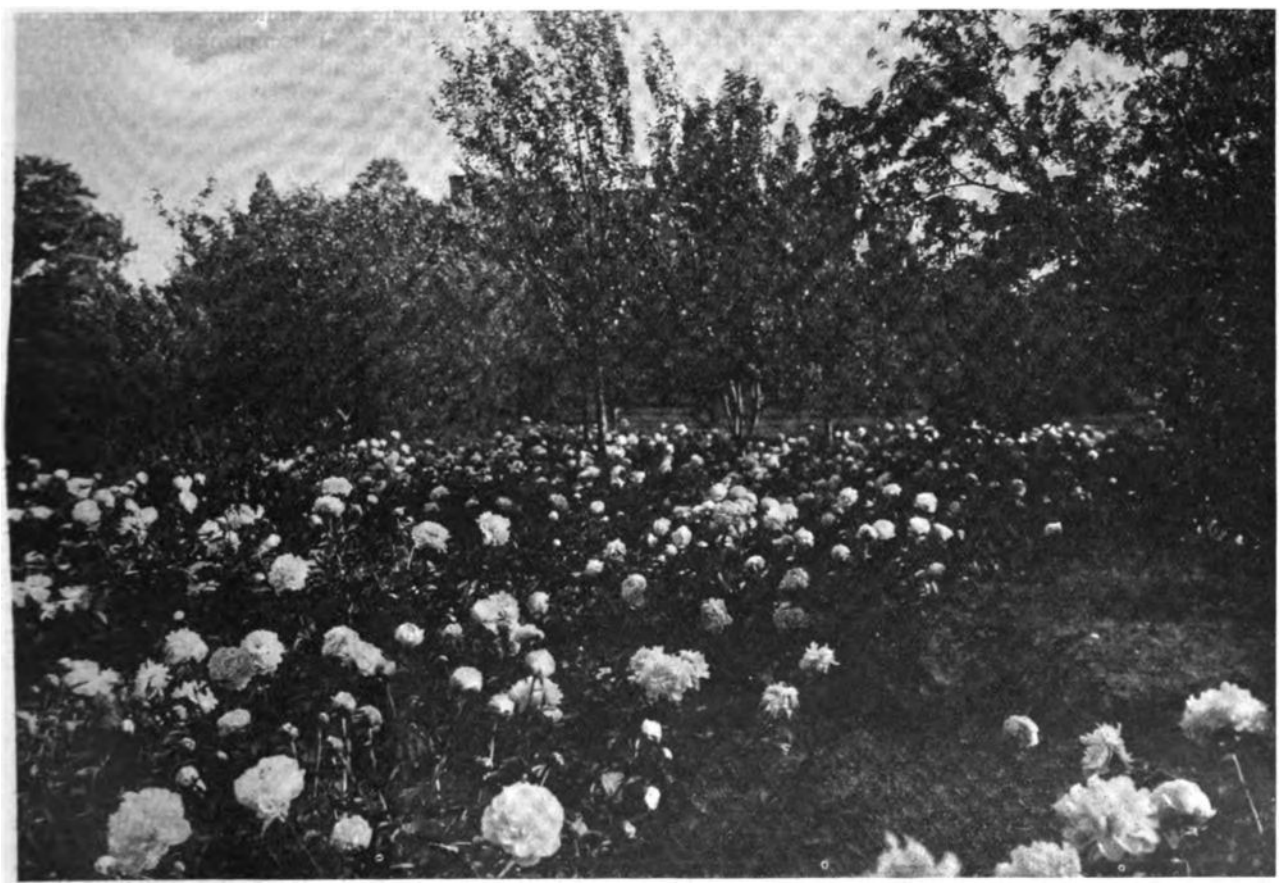
Nevertheless, few are to be found in English gardens. The varieties advertised by English nurserymen are usually limited in number. When in 1921, inspired by my enthusiasm for this flower, I offered three cups to the Royal Horticultural Society to be given as prizes for exhibits of peonies grown by amateurs, the Committee in charge asked me whether I would not prefer to give them for the iris instead. The Committee were of the opinion that there would not be enough peonies available to make a showing.

Yet the peony has a place in English horticultural history as in English literature. It was known in England earlier than the fourteenth century and must have been familiar to and grown by even the very humble. In Langland's "Vision of Piers Plowman," written about 1375, a poor woman is asked by a priest:

> "Hast thou ought in they purs," quod he,
> "any hote spices?"
> "I have pepper and piones" (peonies) quod she,
> "and a pound garlike,
> "A ferthyn worth of fenel seed for fasting days."

Who knows but what the poor woman had bits of P. corallina, that peony once reputed to be native of England in the valley of the Severn! The many allusions to P. officinalis in the old herbals show that there was some general knowledge of the peony at an early date. The materia medica of the Middle Ages included P. officinalis as a cure for many ailments.

On through succeeding centuries, under quaint folk-names, such as pie nanny, nan pie, chesses and hundred bladed rose, the peony held its place in English borders or "knottes." The most enchanting popular name of all was "sheep-shearing rose"—the peony bloomed at or near the time when the sheep were sheared. Not only the humble cared for it, but those of higher rank had an interest in it.



PEONIES IN MRS. HARDING'S GARDEN AT PLAINFIELD, NEW JERSEY.

Digitized by Google

The Earl of Danby, Sir Joseph Banks and the Earl of Sandwich, held it in sufficient esteem to place it in a botanical collection, to inspire a world-wide search for it, and to plant it in a famous private garden.

But to-day, alas, most of England's gardens know not the modern herbaceous peony. Perhaps we, who are so deeply indebted to England for her fine examples of good gardening, may yet happily and in turn inspire our English fellow gardeners with the love of this flower. The country that gave the rose her radiance—so that the very word rose means England—the country at whose feet we sit to learn of rock gardening, of the secrets of lily culture, of the mysteries of her contributions to the wonderful iris of to-day, may then share our delight in this joyous bloom.

A FINE SINGLE PEONY, P. ALBIFLORA THE BRIDE.

In the United States our great enthusiasm for the peony is manifested in various ways. There are many fine private collections, a large number of them embracing well over a hundred varieties of the species P. albiflora. Each year there are exhibitions given over entirely to the peony. Some of the horticultural magazines devote regularly a certain amount of space to peony news. And to supply the material for all this interest there is an ever increasing number of nurserymen and dealers who grow and sell only this especial plant.

In a recent letter to me, Mr. Dykes said that " gardeners in the States seem to be much more enthusiastic than the majority of people in this country " (England). Perhaps we do flame into enthusiasm more quickly—but I think that we American gardeners share the Anglo-Saxon trait of tenacity of purpose, and that we shall have as lasting a love for the peony as the English people have for the rose.

A recent letter from an English friend suggests that the expense of the plants as well as the supposed difficulties of cultivation make a two-fold reason for the neglect of the peony.

In the matter of expense, it may be pointed out that it is only the first step that costs. After that, the natural increase is so steady that visions of unlimited barter and exchange arise. Indeed, the peony may be regarded as a good investment and reliable source of garden income, not for a brief time only, but for years. So hardy that it is not easily killed save by positive abuse, a properly tended plant may bear interest in the form of new iris, choice dahlias, rare and coveted bits of plants not to be bought by mere money, but gladly given in exchange for the peony's beauty; while, with every division of the plant, one's own garden is extended and beautified.

The cultivation is a simple matter if a few fundamental rules are observed. In the United States we have such a wide variety of climate that difficulty attends the culture of the peony in some places. It is a plant for northern countries, and in this respect England is assuredly well located. Even the fogs, if they are not too constant, may be advantageous.

In New Brunswick, Canada, and around the Bay of Funday, peonies grow superbly in the sea-dampened atmosphere. On the Sussex Downs of England they do extremely well in spite of the excessive lime in the soil.

LADY ALEXANDRA DUFF, BEAUTIFUL IN SHAPE AND COLOUR AND SWEETLY SCENTED.

I have never had personal experience in growing peonies in England, but in this country I have learned that they require sunlight for at least a part of the day. For that reason I am at a loss to understand the advice of some English books and periodicals to plant peonies in a shady place. Is it not possible that the results of such advice have done something to discourage the gardeners? With enough sunlight, good drainage and a little attention to the composition of the soil, it would seem that the peony should bloom gloriously in England, and add to gardens already full of charm and dignity the distinction of its frankly exuberant gaiety.

The well known devotion of the Englishman to his roses and his rock garden sometimes gives rise to amusing misconceptions of his interest in other plants. A few days ago a vivacious friend dropped in to see me. " What are you doing now," she enquired plaintively, gazing at my desk.

Digitized by Google

"Come out and play." "I cannot," I replied virtuously. "Many moons ago I promised THE GARDEN that I would write a few words on peonies in English gardens, and at last I am fulfilling that promise."

"Peonies in English gardens!" she exclaimed. "Why, my dear, they will never be grown there. The Englishman cannot raise his eyes above his precious rock garden long enough to *see* a peony or any other flower!" "But you will admit that he raises roses with devotion and success," I protested. "Ah, roses, yes," she replied, "but there you go beyond gardening. You enter the realm of history, of inheritance, of civic decency and national pride. The rose is more than a flower in England. It is a symbol, a fetish, an idol, a legend and a religion!"

Notwithstanding that half-laughing and half-serious prophecy, I still wish so keenly to share my pleasure in the peony that part of the yearly overflow of my garden goes often to gardens abroad as well as at home. To England I have already sent many of these flower ambassadors charged with the duty of obtaining closer horticultural relations and understandings between the gardeners of the two countries. Wisley has a small foundation collection which I sent in 1921. It should be in good flowering condition this year. Last autumn I sent roots to Shakespeare's birthplace, Stratford-on-Avon, and to the Royal Botanic Gardens at Edinburgh. At Chertsey, Surrey, Frank Galsworthy, the artist, has some of the peony roots from my garden. When the plants are sufficiently established to bear typical flowers of full beauty Mr. Galsworthy will put their loveliness into enduring form.

I would like to see our finest American peony, Walter Faxon, in every English garden. There, too, I would like to see many of the other peonies for which we Americans have a passionate admiration: Lemoine's Solange, Le Cygne, Mme. Emile Lemoine and Primevere; Dessert's Souvenir de Louis Bigot, Mme. Jules Dessert, Suzette and Therese; Crousse's Asa Gray, Marie Crousse, Albert Crousse and Avalanche. Many, many others are worthy of a place. In Somerset, Kelway has three of the world's choicest varieties—Lady Alexandra Duff, Kelway's Glorious and Kelway's Queen. I would like to see the wonderful gardeners of Great Britain take the peony whole-heartedly into their lives. And after they had lived with it a while, I think they would agree with me that the modern herbaceous peony is indeed—

Beauty's child, which Nature gat,
For men to see, and, seeing, wonder at.

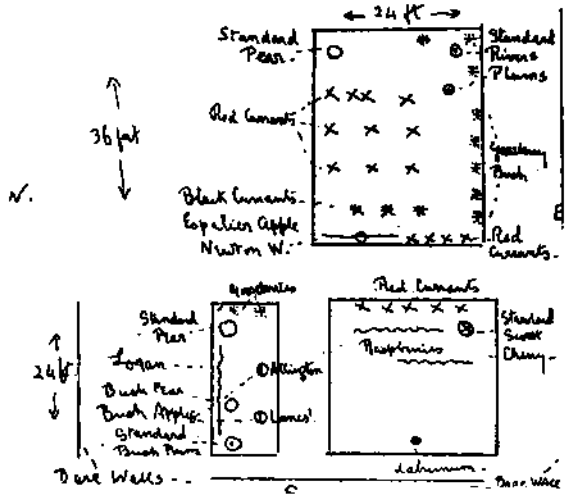
FRUIT-GROWING IN SMALL GARDENS.—II

BY RONALD G. HATTON, M.A.,
OF THE EAST MALLING RESEARCH STATION.

I NOW want to develop more fully by illustrations my eight maxims.

BAD PLANNING.

It is impossible to give an ideal plan for fruit growing in a small garden, because the shape and dimensions of the small garden vary so greatly, but it is possible to enunciate certain general principles of planning and planting, and there is no better way of doing this than by illustrating two actual gardens in close proximity in the same small town and much about the same size, some six rods apiece, by means of ground plans.

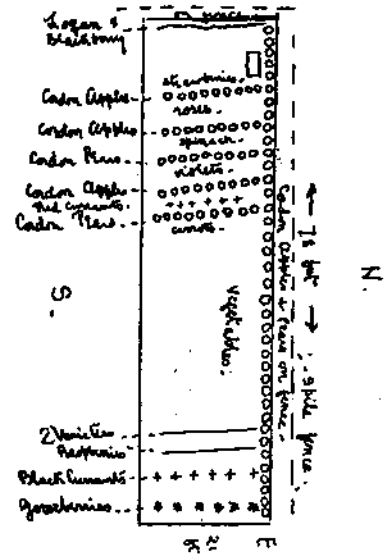


A BADLY PLANNED FRUIT AND VEGETABLE GARDEN.

The first will show you what I call the typically badly planned garden—or rather the garden without plan. The fruit trees have been dotted about here and there without forethought as to ground space or aspect. The result is that there is only one small patch in the garden that will grow good vegetables in freedom, light and sunshine. Elsewhere the vegetable crops are drawn up, spindly and pallid, decreasing in size and vigour as they step in serried rows within the root-range and branch shade of the trees.

The varieties in this garden are badly chosen and, with three possible exceptions are of an unsuitable variety, unsuitably grown. Just pass under review the list:

Two standard River's Early Prolific plums, one of which, if it were a regular cropper, would supply all the early plums



A GARDEN WHICH UTILISES ALL AVAILABLE SPACE TO GOOD ADVANTAGE.

required, but these two trees have only too often raised expectations in vain.

One standard Kent Bush plum, poor in quality, very vigorous and thick in growth—a typical pirate which the commercial grower relegates to the windbreaks. In this garden it holds the strategic position to the south, and glories in the sun bath of which it robs its neighbours.

One standard sweet cherry—probably Kent Bigarreau—spreading its handsome wide arms and still wider roots over a patch of ground 24ft. square. Even in orchards its neighbours give it a wider berth. It contains a perfect feast for the birds and is a grand rendezvous for further depredations upon the struggling vegetable and small fruit crops.

Digitized by Google

One standard Pitmaston Duchess pear. True, a fruit to attract the greedy eye by its size, but mediocre in quality, strong in growth and a bearer only when it approves of its situation.

One standard Doyenne du Comice pear. What can one say before this queen of fruits, except that it requires the courtship of special mates, from which it is here exiled, and that it is most illusive in its favours and fickle in constitution?

These six standard trees would all necessitate the hire of a twenty-stave ladder for a considerable portion of the year to harvest the crop and thin the branches. If they needed spraying, they could not be dealt with effectually without a power machine!

One espalier-trained Newton Wonder apple stands ostentatiously spreading limbs against the sun to screen an otherwise eligible piece of vegetative ground. It is proud to be the only representative garden tree amid such a motley crowd, but is somewhat impatient of its training, for it is in a soil and probably on a root stock on which it resents restrictions.

Two bush apples, Lane's Prince Albert and Allington Pippin, both of which should find a proper place in the small garden, struggle with a bush William's Bon Chrétien pear on a patch of ground 9ft. by 24ft., already occupied by two standard fruit trees! Moreover, these bushes are of the old type with branches radiating from the ground level, thus challenging all attempts at cultivation.

It is impossible to describe the planting of the small fruits, though they are like the youngsters among a crowd of elders, jostling on the kerbstone, peering between their legs and arms at some passing pageant. What a motley crowd of rag-a-muffins!

Three black currants, fifteen red currants and thirteen old gooseberries all of single variety, two invading rows of blatant Red Cane raspberry (Bath's Perfection), that noted cane-maker and bearer of fruit fit only for the whosesale jam boiler! Bindweed and water grass are curling round the old gooseberries grown as stools. Red and black currants alike knew little pruning until recently.

Finally, this garden is walled on three sides, there is a north wall, an east wall, and a west wall—bare but for one bemildewed rambler rose and the tentacles of a neighbourly but inquisitive virginia creeper.

GOOD PLANNING

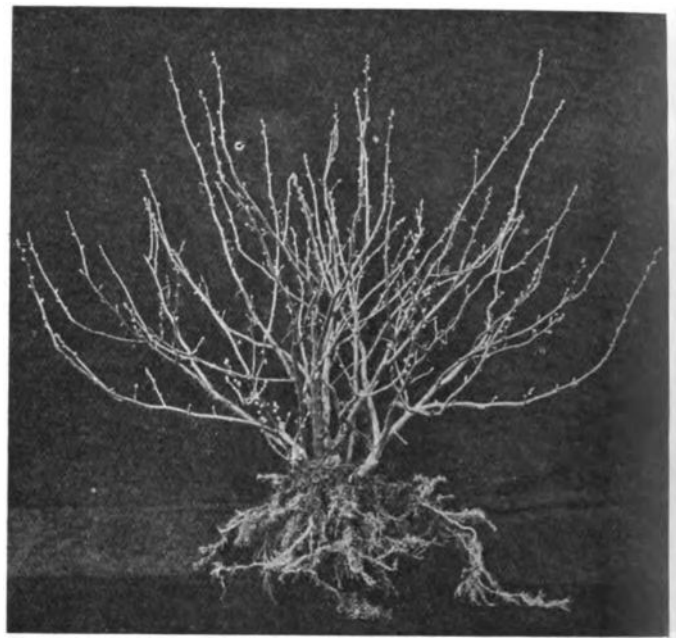
Let us now take the second garden, although not ideally planned in every detail, yet it is well thought out in principle. Along a spile fence to the north, sloping cordon apples and pears, at 3ft. apart, are trained. They help to break the winds for the more tender crops in front, and, in blossom and fruiting time, form a picturesque screen.

To the east end, where the house throws some slight shade, are relegated in neat rows, running south and north, six black currants, six gooseberries and two rows of raspberries. The gooseberries are chosen sorts, two May Dukes for picking early green or ripening red, two Lancashire Lads mid-season reds, Leveller, a large dessert yellow, and White Lion, a later and large dessert white. These latter are cautiously thinned as soon as the fruits are sizable for cooking. All of their type are chosen for compactness, and are grown on a short leg. These bushes are capable of yielding an average of 5lb. or 6lb. apiece and should supply all the household needs. The six black currants are of two varieties, planted two and one, four of the dwarf heavy-cropping Baldwin type, suitable for puddings and jam, two of the erect Goliath breed, with fruits extra large, and sweet enough to tempt the thirsty on a hot July day. The sprawling uncertain Boskoop Giant, and the jam makers' acid French varieties are wisely avoided.

Next come two rows of raspberries. One is Pyne's Royal, sturdy, but not profuse of cane, bearing a magnificent show fruit of superlative type. The other row is Norwich Wonder, again none too rank of cane, but in this garden ground thriving and justifying its place by flavour. Note how these small fruits are concentrated together within reach of the house and easy of protection from birds.

Beyond this, an open space is left for general vegetable culture. The southern boundary of the garden lies open to the sun with narrow flower border, but no sheltering trees.

Towards the western end of the garden, rows of trained cordons are planted, running south and north, so that the sun beats down the rows. These make a mystery of

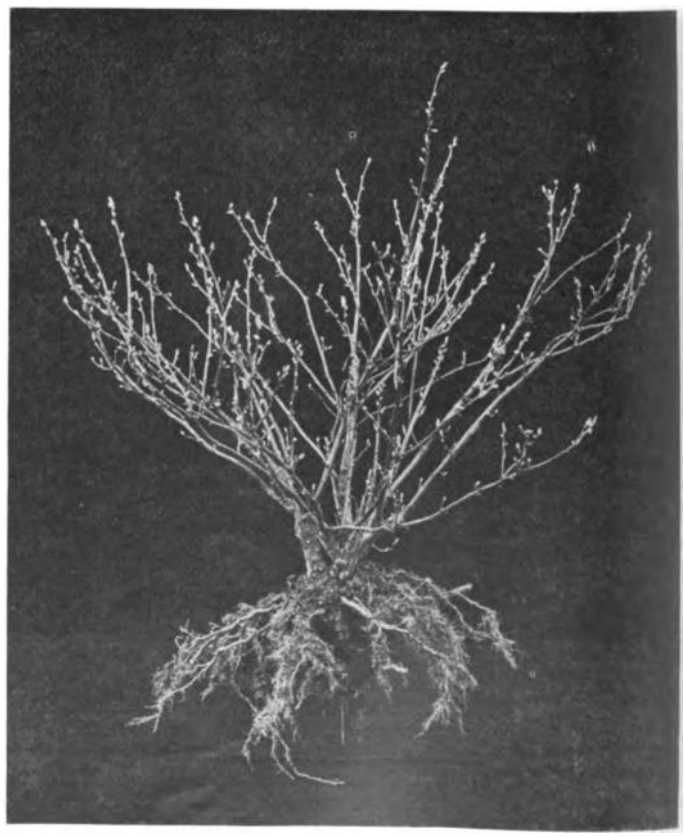


THE SPRAWLING, UNCERTAIN BOSKOOP BLACK CURRANT.

garden ends, indeed suggest that there is no ending, and, as one glances latitudinally down the neat rows, they give a pleasurable effect of vista in a breadth of but twenty or so feet!

Between the rows of trees, 2ft. by 5ft., are here a wonderful assortment of small crops. Carrots, violets, spinach, dwarf roses, strawberries, and here a row of red currants, three dwarf heavy cropping compact Fay's Prolific, and three Laxton's Perfection, a recent and choice contribution.

Pursue the garden to the end; beyond the cordons is a warm corner for the never sightly forcing frame, and, on the western fence, the profuse-caned logan and Laciniatus (cut-leaved blackberry) entwine their branches in a leafy screen.



THE COMPACT, HEAVY CROPPING BALDWIN BLACK CURRANT.

NOTES ON LACHENALIAS

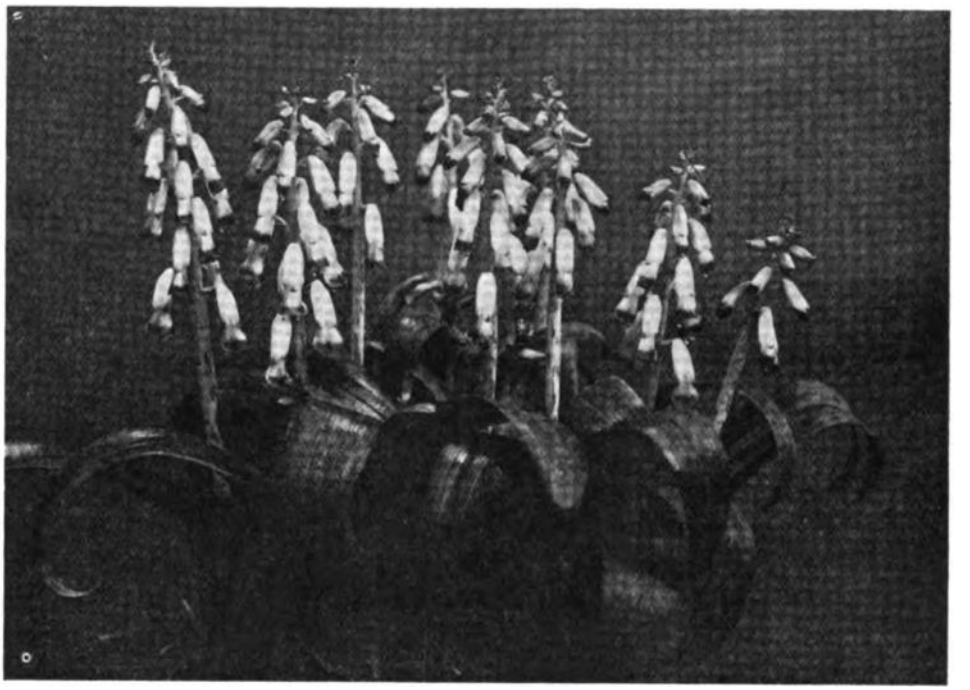
BY THE REV. JOSEPH JACOB.

SURELY one of these days lachenalias will wake up and find themselves famous. Might I have added "again"? This I do not know. I have no data to tell me whether the many pictures of different species that appeared in various botanical and garden publications of the early part of last century were an index of a widespread popularity; or if the new hybrids of Nelson and Moore of a much later period ever caught on to any appreciable extent, with the sole exception of the beautiful yellow Nelsoni, which in these present days may be termed the show child of the family. There have been times when lachenalias were grown in gardens here and there, where homes were found for the out of the way and the interesting in contradistinction to the brighter-looking and more ordinary flowers. But "As good be out of the world as out of fashion"; and so it has been with lachenalias.

Thanks to the advice of my good friend Sir Frederick Moore, who furnished me with the greater part of my first stock-in-trade from his collection at Glasnevin, I have been engaged for a number of years in raising seedlings, and although it was with the greatest difficulty I got through the trying times of the great war, I think I may say I am getting into my stride again. It must be at least ten years since I sent a box of blooms to Lady Moore to ask her opinion and got as answer back the greatest compliment a worker could have had paid him, "Never, Mr. Jacob, come to Glasnevin again for lachenalias; we are coming to you." I am better now than I was then. I have got more substance, size, strength and strangeness of colouring into many of my latest varieties. Hence I ventured upon my opening remark, "One of these days lachenalias may find themselves famous." *But more workers are wanted.* I see visions of future developments which, if they could be proved possible, would revolutionise everything. What, I wonder, would happen if the sweetness of glaucina or the even greater sweetness of the newly baptised convallariodora (*Botanical Magazine*, New Series, Plate 8955) could be given to my beautiful Siam—for whose character I refer readers to Mr. William Mauger of Guernsey—or, even better still, to what might so easily be a favourite Christmas stand-by: the red pendula? Suppose someone were to work on L. pendula alone or (as I find I did) in conjuction with aureliana, which is said to have been found growing wild in Provence (*Revue Horticole*, 1890, p. 396), but which is in all probability just a seminal variety of pendula? There are great possibilities, as Mr. "Capability" Brown would doubtless have said, had he seen, as I did, a second generation brought to its flowering. Or, again, Marvel's Mower* notwithstanding, suppose a cross could be made between a lachenalia and some near relation, say, a veltheimia, what then?

Lachenalias should always be exhibited in a growing state in their pots, but how seldom do we come across them like this. Even if we do, are we looking at the stumpy prehistoric forms that might have passed muster in the days of the ancient Mower about 1650, but which are back numbers according to the taste of 1924?

Lachenalias are the very plants for a *cool* greenhouse. Bob Short, the tabloid rule-maker, might sum up their requirements thus: No frost, no cold draughts, no hard forcing, plenty of air, light rich soil, August potting, thorough ripening, cool growing. We start our bulbs about mid-August. They begin life in a coldhouse or frame and are given all the air possible. When frost comes they are brought into a greenhouse and sufficient fire is provided to keep a minimum night temperature of 35°. We give them doses of "Clays" and weak soot water once a week from about January onwards until the foliage turns yellow, just omitting the period when they are in flower, which with our cool-house treatment is February and March. After flowering, the plants receive the same attention as they had before that time, until the yellowing of the foliage shows that their period of rest is coming on. This will probably be about the middle of May. From this time onwards the bulbs should be kept dust dry in their pots and baked until starting time comes round once more. I strongly advise pans or low flower-pots to be used. In these we put six bulbs in a 5in., seven or eight in a 6in., and fourteen or fifteen in a 9in.



LACHENALIA ROSEMARY, YELLOW BELLS WITH DEEP CLARET EDGES

SEED SAVING.—Hand fertilisation is necessary. The anthers should be taken away before the flower is really open, as they dehisce in an early stage. Seed should be sown *very* thinly in pans in August—½in. between each seed is about right. The pans should be put in a coldhouse. Germination takes place in five or six weeks. The young seedlings are grown on exactly like the old bulbs, and with them are turned out in July and put in small paper bags ready to be graded and potted in August. Some of the larger ones will bloom the following year. All will flower the year after that. Thus, some seedlings from seed sown in 1924 will bloom in 1926 and all in 1927.

Lachenalias follow a very general rule. The nearer the seed stage, the stronger the plant. Eight or nine inch pans full of first-time flowering seedlings are enough to melt the hardest heart and to convert the most obdurate. There is no fear of any jarring of colours. Pendula seedlings excepted, all the others harmonise with one another. They will be all of them of some shade of yellow or orange, with or without claret-coloured edgings to the petals, and with yellow, orange or red tops to the spikes. These are the colour notes with which the floral harmonies of all lachenalias are composed, with the exception of certain species like racemosus, glaucina and convallariodora.

* The pink grew then as double as his mind,
The nutriment did change the kind;
With strange perfumes the roses he did taint;
And flowers themselves were taught to paint.
—"The Mower Against Gardens," by Andrew Marvel.

NEW AND RARE CONIFERS

BY E. H. WILSON,
OF THE ARNOLD ARBORETUM.

[We have received from Mr. Wilson notes on a few rare conifers which have come into cultivation within the past few years. All the photographs have been taken by Mr. Wilson, and it is the first time that these trees have been illustrated in any periodical.—ED.]

AMONG the many surprises of the Chinese flora not the least is its richness in conifers. A large number of species of picea and abies have been described in recent years and many are now in cultivation in America and Europe. I have introduced some thirteen species and two varieties of picea and seven species of abies, all considered new. Patience is very necessary in raising conifers from seeds, and still greater patience in waiting until they develop their true character and prove their value as garden plants. In 1902, and again in 1904, I secured seeds of a few species for Messrs. Veitch, but it was not until 1910 that I made a real haul of seeds. The fruiting of picea and abies is intermittent, and depends very largely on weather conditions in the spring when the flowers are open. A late frost may ruin everything. In 1910 the fates were propitious and the conifers of western Szechuan fruited abundantly. These seeds were sent to the Arnold Arboretum and by that institution distributed widely in Europe as well as in the United States. They germinated freely, and now, after thirteen years, it is possible to tell a little about the plants.

The climate of Massachusetts is both rigorous and changeable, and plants—evergreens especially—have to be tough in constitution to withstand its severities. This will be better understood in England when I say that none of the conifers of western North America—that is, the region west of the Rocky Mountains—can be grown in the Arnold Arboretum. The form of Douglas fir grown here is that from Colorado and that of the giant thuya (Thuya plicata) from Idaho. Of the firs from China, Abies Fargesii, A. chensiensis and A. recurvata promise to be hardy and useful species in the Arnold Arboretum. The spruces, with the exception of the flat-leaf species, have proved even more adaptable, for all introduced are thriving and it appears probable that several will be of great value to the gardens of New England and elsewhere. There are three very promising new species, Picea Balfouriana, P. Wilsonii and P. asperata. The appearance of P. Balfouriana, when 6ft. tall, may be gauged from the accompanying illustration.

PICEA BALFOURIANA IN WESTERN SZECHUAN.

A SIX-FOOT SEEDLING OF P. BALFOURIANA AT THE ARNOLD ARBORETUM.

PICEA BALFOURIANA.

As we know it under cultivation, Picea Balfouriana is dense in habit, with arching, overlapping branches and acute, dull green ½in. long leaves, pointing forward and downward with prominent stomatic lines on the under surface. The shoots are slender, pale grey and pubescent; the winterbuds chestnut brown, ovoid, non-resinous, with closely imbricated, puberulous bud-scales. In its adult stage this spruce is a tree upwards of 100ft. high and among the tallest of the Chinese species. The trunk is mast-like, with short, spreading branches which give a spire-like appearance to the tree. It has grey, deeply furrowed bark and handsome, violet-purple cones with membranous, flexible cone-scales, undulate and laciniate at their

Digitized by Google

apices. The wood is resinous, close-grained and easily worked, and the timber is valued for general construction purposes.

This species is a common constituent of the high-level forests of the Chino-Tibetan borderland between elevations of 10,000ft. and 12,500ft., and is the most alpine of the Chinese spruces. It was discovered and introduced by me in 1910 and is named after Mr. F. R. S. Balfour of Dawyck, Peeblesshire, a lover and enthusiastic planter of trees.

(To be continued.)

FLOWERING SHRUBS FOR A MODERATE-SIZED GARDEN.—III

BY W. J. BEAN.

CISTUS AND HELIANTHEMUM.

FOR a sunny spot or a hot gravelly slope the rock roses or cistuses are very well adapted. The genus is a large one, but, unfortunately, the great majority of the species are not hardy with us. I would recommend the following: Cistus cyprius, a hybrid and the finest of the tall kinds, hardy, and inheriting much of its beauty from C. ladaniferus (one of its parents), its blossoms having the same white petals with a crimson blotch at the base of each; C. Loreti, another hybrid from ladaniferus, with flowers 2½ins. wide, white, similarly crimson blotched; C. corbariensis, a very hardy sort, also a hybrid, growing 2ft. or 3ft. high, very bushy and leafy, flowers pure white except for a yellow stain at the base. C. purpureus is a singularly beautiful plant with reddish purple blossoms conspicuously blotched at the base with dark red, but it is too tender to be relied on near London.

The sun roses, or helianthemums, are closely related to the cistuses and also like full exposure to sunlight. If restricted to one species, I would grow H. formosum, a low, spreading shrub, very hardy, whose brilliant yellow flowers have brown-purple stains near the centre. All these cistuses and helianthemums are easily propagated by summer cuttings. Their flowers see the sun rise once only and usually fall soon after midday, but Cistus Loreti keeps them open a few hours later.

SPIRÆAS constitute a large group and they have hybridised so much that they have become rather bewildering. One section of the genus has pinnate leaves and large panicles of small white flowers borne at the end of the current season's leafy shoots. Spiræa Aitchisoni and the new S. arborea from China may be selected to represent it. Another section of the genus bears small, flattish or rounded corymbs of white flowers, and of this section I would grow SS. canescens, Veitchii and Van Houttei. S. discolor is a very graceful shrub up to 10ft. or 12ft. high, producing large panicles of creamy white blossom in July. S. arguta, one of the very best, has pure white flowers clustered on its leafless twigs in April. Finally, there is the late-flowering group of which the flowers come in panicles or flattish trusses terminating the leafy shoots from June to August; one of the best is Anthony Waterer, a form of S. Bumalda with bright rose flowers; another is S. Menziesii triumphans with reddish purple ones. These few species will represent a large genus in most of its sections.

THE JAPANESE SNOWBALL TREE, V. PLICATUM, STILL HOLDS FIRST PLACE AMONG VIBURNUMS FOR SHOWINESS.

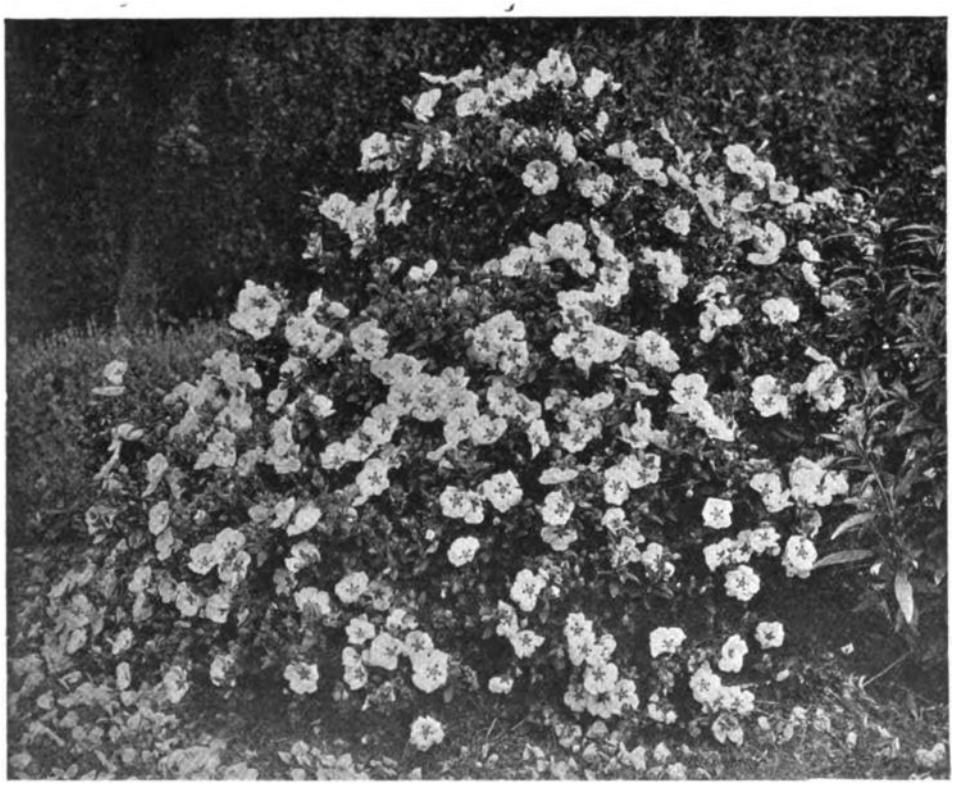
CEANOTHUS.—Many of the ceanothuses are tender and need wall protection. If wall space can be spared, the evergreen CC. rigidus, papillosus and Veitchianus should be grown; while in the open, C. thyrsiflorus and the hybrid Gloire de Versailles may represent the genus. All these have bloom of some shade of blue, the most uncommon of all colours among trees and shrubs, but some hybrid ceanothuses like Ceres and Perle Rose have pink ones. Two other blue-flowered trailing shrubs may be mentioned here, Vinca major and V. minor, both evergreen and both useful as a ground cover and not averse to a moderate amount of shade.

ERICACEÆ.—I will not venture on the subject of rhododendrons here: like that of the roses, it is so big that it can only be treated separately; but there are a goodly number of shrubs belonging to the same family—the Ericaceæ—which should not be left out of any garden the soil of which is free from lime. The best of the ericas, or heaths, have already been referred to. The arbutuses are excellent evergreens, luxuriantly

Digitized by Google

leafy, flowering in autumn and spring. A. Unedo, the strawberry tree, is also handsome for its crops of orange-red fruits. A. hybrida in numerous forms is useful for giving background and shelter, attractive also for its flowers and red-brown bark. A. Menziesii, the Madroña of the Californian woods, is rather difficult to obtain and requires care to establish, but if possible

SPIRÆA ARBOREA, A GIANT FROM CHINA.



CISTUS LORETI, WHITE WITH CRIMSON BLOTCHES.

it, too, should be grown for its cinnamon-coloured branches. It does not bear transplanting well and should be obtained from nurserymen in pots and put in its permanent place while still small. Two species of Kalmia, glauca and latifolia, are pleasing evergreens with more or less rose-coloured flowers; and so are the two commonly grown species of Pieris (or andromeda), japonica and floribunda, with white ones. Enkianthus campanulatus is deciduous, and besides the charm of its abundant bell-shaped blooms it is one of the most exquisitely coloured of all shrubs in autumn. Clethra alnifolia is also deciduous and valuable in blossoming as late as August; the white flowers are in erect racemes and spicily fragrant. For the beauty of its fruits late in the year—and they vary in colour from pure white to pink, lilac and crimson—Pernettya mucronata is always worth a place.

VIBURNUMS.—Chinese exploration has added much to the variety and interest of the viburnums, especially in regard to beauty of fruit. In this respect none surpasses V. betulifolium and V. lobophyllum, both of which carry heavy crops of bright red berries. For flowering I would still give first place to V. tomentosum, especially var. Mariesii and the sterile form, plicatum. The pink-tinted flowers of V. Carlesii are both beautiful and alluringly scented, but are too often spoiled by spring frosts in the open. The old guelder rose, V. Opulus, is still one of the best of viburnums for beauty of fruit, as its variety sterile, the snowball tree, is for beauty of blossom. V. Tinus, commonly known as laurustinus, is, and for centuries has been, one of the indispensable evergreens of gardens, belonging to the same useful class as Berberis stenophylla. Its dense habit and richly green foliage is admirable for shelter and as a screen or a background. It is always cheerful-looking, and flowering as it does at any time in winter and spring, as the weather goes, it is, on the whole, scarcely exceeded in value by any other shrub.

MOCK ORANGES (PHILADELPHUS).—So much alike are these that the names of the best will almost suffice without further remark. Of the true species I would select PP. latifolius, Lewisii and grandiflorus among the tall growers, and the richly fragrant P. microphyllus among the dwarf ones. From the last named, crossed with P. coronarius, was raised P. Lemoinei, one of the best of all hybrid shrubs. Of the other numerous hybrids, Virginal, Pavillon Blanc and Manteau d'Hermine are excellent. All are easily grown in rich loamy soil and easily propagated by cuttings.

LILACS.—A considerable number of lilacs have been added to our collections by recent collectors in China, and several of these new species are very handsome. Most of them, too, flower in June, a few weeks after the ordinary "lilac-time." One of the best is Syringa reflexa, very distinct in its cylindrical, pendulous or arching panicles, densely packed with purplish red blossom. But none of them can compete in attractiveness with the improved forms of the old, well loved, May-flowering, common lilac. The French nurserymen continue to send out new varieties of their own raising, but many of these it is difficult to distinguish from older ones. I would still grow Marie Legraye, Mme. Lemoine, Souvenir de Louis Späth, Ellen Willmott and Francisque Morel. Still full of charm, too, remain the old Persian and Rouen lilacs.

DIERVILLA (or "Weigela," as the genus is still often called) contains some splendid flowering shrubs, of which again the

Digitized by Google

most ornamental are of hybrid or garden origin. Abel Carrière with rosy carmine flowers still holds its place, although raised a good many years ago. Mme. Lemoine, too, is good, with flowers at first white and then pale rose. A very distinct and handsome sort is Eva Rathke, its blossoms dark crimson. Of the true species D. florida (frequently called Weigela rosea) is, perhaps, the one to be relied on for good looks and happy disposition, just as its variety candida remains one of the best white-flowered sorts.

DEUTZIA.—Of deutzias a number of new species have recently come from China, and French nurserymen keep on sending out new hybrids. In both groups there are many undoubtedly beautiful things, although I am, perhaps, prejudiced against them through the flowers being almost invariably destroyed at Kew by spring frosts. There, however, the situation is low and flat and, in more favourable or elevated localities, the deutzias are well worth growing. D. longifolia, and more particularly its var. Veitchii, is in my experience the best of the new Chinese kinds, but none, I think, is on the whole so valuable as the old D. scabra (or crenata), introduced over one hundred years ago, especially the variety called "Pride of Rochester," of which the petals are suffused outside with rose, and the var. candidissima, with pure white flowers.

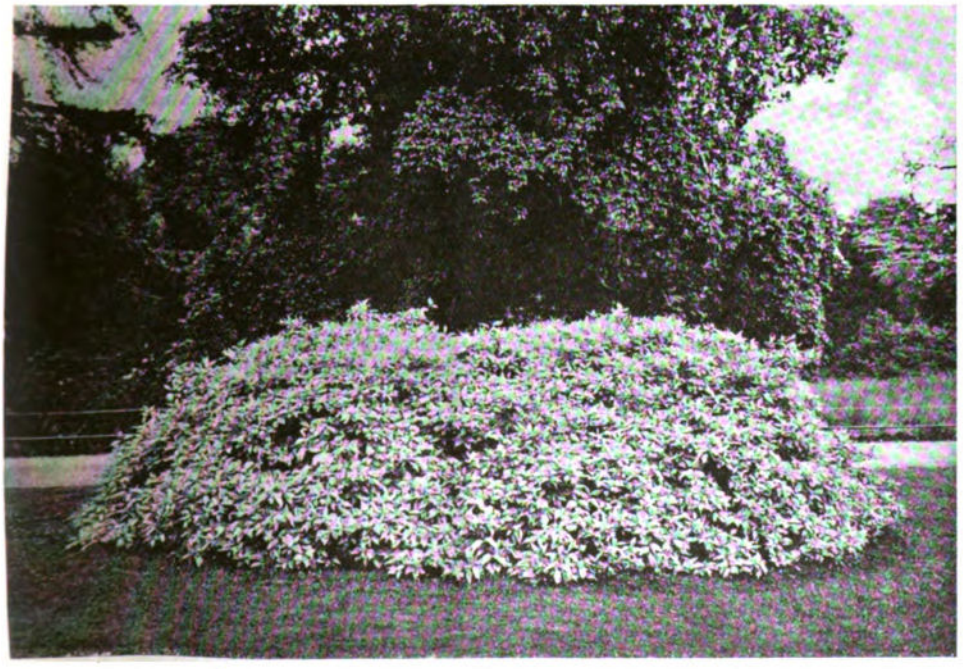
ARBUTUS UNEDO, THE STRAWBERRY TREE.

RABBIT-PROOF PLANTS

BY SIR HERBERT MAXWELL, BART.

THE following remarks must be taken subject to this limitation: they are founded on observation in a district where winters are usually very mild.

Seven-and-twenty years ago, thinking to render some slight service to fellow sufferers from these irrepressible rodents I published such a list in a volume of open air notes.* From that distant day to this present, correspondents, known and unknown, write to me expressing incredulity or indignation—sometimes both—describing how, relying on my warranty, they have planted this, that or the other, only to find it stripped and destroyed in a night or two. Yet methought that I had not written without good material for opinion. Many years ago my father made a resolute effort to put down rabbits upon that portion of his land on which he kept the shooting in his own hands, the remainder being let. The result was that, on 8,000 acres, 22,300 rabbits were killed in eight months, besides those—number unknown—killed by the tenant farmers. Rabbits have never been so numerous since; but it requires incessant attention to keep them within reasonable limits.



CORNUS ALBA SPAETHII, CONSIDERED TO BE RABBIT PROOF.

No doubt plants are more liable to suffer injury from rabbits in cold inland districts, or even on the east coast, where vegetation is less luxuriant than in the milder west where my experience has been gathered. But even here we have to protect many newly planted things which may safely be left unprotected after they have become established. A case in point occurred here last year. In a certain wood much frequented by rabbits there had grown for as long as I can remember (and that is a precious long time!) several large clumps of Turk's cap lilies—L. pyrenaicum. Even the most depraved or malignant rabbit never set tooth to them; they flowered and flourished luxuriantly, until the wood grew so thick—the shade so dark—that I had the bulbs lifted last spring and replanted in the open, never dreaming of protecting them with wire netting. They grew away freely until about a foot high, when almost every stem was stripped

* "Memories of the Months." First Series, pages 91–4. Second Series, pages 48–9, 293–5.

Digitized by Google

of leaves, several stems being gnawed right through. Next spring I shall remove the wire netting which has been put round them, and shall be surprised if any notice is taken of the lilies, which by that time will have become thoroughly established.

Among forest trees there are only three species which we have found it quite safe to plant without protection, namely, Sitka spruce (Picea sitchensis), which defends itself by its armature of sharp needles; the monkey puzzle (Araucaria imbricata), which is effectively sheathed in plate armour; and the Corsican pine (Pinus Laricio). This pine presents a puzzling case. Most botanists regard it as being of the same species as the Austrian pine; yet Austrians will be devoured as fast as they are planted, whereas Corsicans are left severely alone. All deciduous forest trees invite, and usually suffer, attack when first planted, though I do not remember having seen alder or hawthorn disfigured; but three or four years' growth after planting renders all of them safe, except ash, holly and laburnum, which are often barked even after reaching maturity.

Now as to shrubs, we have found that the following species require no protection, except those marked with an asterisk, which should be guarded with wire-netting until well grown:

Rhododendrons (including azalea), all species and hybrids, except those with small leaves, such as RR. glaucum, Augustinii, præcox, etc., which should be wired in till well grown.

Kalmia latifolia.

Mexican orange (Choisya ternata).

Honeysuckle (Lonicera), all species, both bushes and climbers.

Butcher's Broom (Ruscus aculeatus).

Box (Buxus sempervirens).

Spurge laurel (Daphne Laureola).

Snowberry (Symphoricarpus racemosus).

St. John's wort (Hypericum), all species.

*Spindlewood (Euonymus europæus and E. latifolius).

Guelder rose (Viburnum Opulus, lantana and *Tinus).

Syringa (Philadelphus), all species.

Lilac (*Syringa), all species.

Fuchsia Riccartoni and F. globosa.

Dogwood (Cornus sanguinea, C. Kousa, etc.).

Sea buckthorn (Hippophæ rhamnoides).

Rose (Rosa), all species.

Spiræa, all shrubby species.

*Deutzia, all species.

*Staphylea colchica, S. holocarpa, etc.

Red-berried elder (Sambucus racemosa).

Rhus, all species.

Hydrangea hortensis, HH. paniculata and vestita.

Ribes, all species.

*Arbutus, all species.

*Escallonia, all species.

*Diplopappus (Cassinia) fulvida.

Bamboo (Arundinaria, Bambusa, Phyllostachys, etc.).

*Erica arborea, EE. alpina, lusitanica, etc.

All species of barberry, except those of the Mahonia section, are specially liable to be eaten when young, but are pretty safe when they have grown strong. Shrubby veronica, olearia and senecio are vulnerable at all ages.

PAMPAS GRASS WHICH IS TOO TOUGH FOR RABBITS.

Among herbs, we have found that most of the strong-growing Composites, such as aster, buphthalmum, inula, petasites, etc., can take care of themselves in the open. The milky juice of most of the bell-flowers (campanula) presents irresistible attraction to both rabbits and pheasants, yet the noble native C. latifolia and the Caucasian C. lactiflora spread freely from seed in our woods, although these are populated with ground game. All species of narcissus are immune from attack by browsing animals in virtue of the presence in their roots and leaves of innumerable bundles of crystallised calcium oxalate, technically known as Raphides. Snowdrops and snowflakes, also belonging to the Amaryllis Order, enjoy the same immunity, but I do not know whether that is owing to the presence of Raphides in their tissues. The crocus, belonging to the Iris Order, is destroyed at once if unprotected, while of the genus iris I have found that, while bulbous species are devoured by rabbits, the flag section is left alone. In the Lily Order most species are never attacked, colchicum, kniphofia, polygonatum, funkia, convallaria, scilla, trillium, asphodelus, hemerocallis, ornithogalum flourishing unhurt in our woods and lawns; but fritillaries, tulips and grape hyacinths are esteemed as delicacies by the furry foe. The dog-tooth violet (erythronium) may spread its beautiful mottled leaves with impunity; but if there are pheasants about they will not spare you a single bloom. Of the genus Lilium, LL. pardalinum, martagon, superbum, pyrenaicum, tigrinum and a few others are fairly safe in woodland when well established, but should be well protected when first planted. The great shining leaves of L. giganteum might be expected to attract rabbits, but I have never known them to be touched.

The following herbs may be pronounced safe from attack:

Periwinkle (Vinca), all species.

Gentian (Gentiana), all species, especially the willow gentian (G. asclepiadea), a fine plant for naturalising.

Mullein (Verbascum), probably all species.

Foxglove (Digitalis), all species.

Windflower (Anemone), all species, but pheasants destroy the leaves of garden varieties.

Primrose (Primula veris), but the coloured garden varieties are sure to be eaten down when first planted. PP. japonica, pulverulenta, helodoxa, etc., are easily naturalised, but sometimes suffer where rabbits are numerous.

Globe-flower (Trollius europæus). I have not tried the Asiatic species without protection.

Meadow-sweet (Spiræa), all herbaceous species.

Saxifrage (Saxifragas umbrosa, granulata and a few other species), but not the Megasea section.

Stonecrop (Sedum).

Monkshood (Aconitum Napellus and others).

Winter aconite (Eranthis hyemalis).

Pampas grass (Cortaderia).

Arundo (Arundo Donax and A. conspicua).

Zebra grass (Eulalia zebrina).

Crane's-bill (Geraniums phæum, pratense, armenum, etc.).

Orchis, all hardy terrestrial species.

New Zealand flax (Phormium tenax and P. Cookianum).

Digitized by Google

PRUNING ROSES

BY HERBERT L. WETTERN.

So many books have been written on roses, each with at least a chapter on pruning, that there is apparently little to add to the prescribed formulæ and methods of operation, but *experientia docet*, and everyone's experience seems to differ in some respect—hence a few additional notes on HOW, WHEN and WHERE to prune our plants.

Some books tell you to prune hard "the first year after planting." This is not quite clear to the novice, and might be expanded so as to be self-explanatory. For example, roses which were planted last autumn and during this winter should be cut back very hard during this month. If, however, planting has been delayed until March itself—then prune immediately after planting.

This first pruning must really be very hard—almost down to the ground. The second year, that is after the first year's growth, is the critical time for the future of the plant as regards appearances and health. If the first good new shoots are not pruned sufficiently and thus left too long, the plant will probably and for ever after be leggy. Try, therefore, to keep a good bushy shape, and gradually build the plant up year by year, and then, when the older shoots are worn out with age, new shoots will have come forward and be undergoing similar treatment.

In pruning, take a good look at the plant before commencing operations, and deciding what to cut away, treat it individually and be sure of your objective before commencing. On no account start indiscriminate hacking off. You may find yourself at the finish with a ruined plant.

Cut out all dead wood first, then small thin growths which can never bear full-sized flowers. Also cut out ingrowing shoots, *i.e.*, shoots which have tended to grow across the centre of the plant, for rose trees grow better with open centres where light and air can get at them, just the same as fruit trees.

If any old wood is found discoloured brown in the centre, cut it clean away until normal colour is reached, for it is dead, even though the sap may continue to flow up to the new shooting buds. If there are black blotches on new wood, cut right back below them, for they indicate frost bite and cannot thrive. Perhaps some of the new shoots which came late last autumn have never ripened and appear soft and sappy; cut them also clean out to their bases.

You need not expect to find all these defects on one plant, but in the course of pruning a number of rose trees you will doubtless come across many examples of each type on which the knife must be used unsparingly. Having eliminated these, you should now only have the good growths to operate upon, which you will do "according to instructions."

Never do your pruning to mere mechanical measurements, but work to buds. The buds of Lady Plymouth sometimes run four inches apart, while those of Mme. Ravary average a half inch apart, so your pruning can only be according to the buds themselves; and always try to prune to buds pointing outwards.

A. A HYBRID TEA UNPRUNED.
B. OLD WOOD AND WEAK SHOOTS REMOVED.
C. PRUNING COMPLETED.

The late Mr. George Prince, the well known Oxford rose grower, used to tell of a lady who asked advice as to pruning, and was, unfortunately, instructed to "cut the plants down about two-thirds," so she promptly cut a new lot of *standards* down to about one-third their height from ground level!

Upon the ever vexed question of knife *v.* secateurs, the former undoubtedly makes a cleaner cut, and with pruning roses a clean cut is as essential as in a surgical operation; but for speed the secateurs are preferable, and provided they are sufficiently sharp to make a close cut, the risk of injury to the bark is negligible.

Here at Oxted we have to rely upon secateurs, for, with nearly ten thousand rose trees of all ages to operate upon, we could never complete our work in time. The expensive novelties are, however, treated to the more tender mercy of a razor blade.

With climbers, which throw new shoots from the base, such as the Wichuraianas, we find it best to cut out all the previous year's wood, provided, of course, there are new base shoots for the current year's flowering. Erect growers, such as Blush Rambler, American Pillar, etc., which throw new shoots from the base and from existing shoots, we cut back as hard as possible, *i.e.*, take away the old wood above such new lateral shoots.

Bear in mind that, in pruning, the same argument applies to such climbers as to dwarfs, namely that if you want good blooms or good trusses of bloom, you must prune reasonably hard. Look at the paltry blooms on an *unpruned* plant, say, of Dorothy Perkins as compared with the big trusses with long stems with which you are rewarded when the blooms are on new wood only.

We have never had the heart deliberately to prune the new wood of a Wichuraiana down to three or four feet, but a year or two ago, by accident, we broke a long new rod, with the result that the two feet which remained of it produced a few enormous trusses of bloom on long stems, which we exhibited at a suburban show. The raiser of the rose, who was present, remarked that he had never seen such wonderful trusses of bloom.

As to *when* to prune, this month of March is always reckoned the time for hybrid teas, etc., and early April for teas, but a good deal depends on the season.

Here, where we have in many cases thirty to forty plants of one variety in a bed, we never prune all at once, but spread the pruning over three or four weeks, with the idea of prolonging the first blooming season. In a normal year, without extremes of temperature, this plan is successful, but if the growing months

Digitized by Google

continue cold, followed by a sudden rise in temperature in May, the sap rushes up and little advantage is gained in the way of prolongation of blooms.

With exhibition roses we prune a few of each variety every week from the middle of February until about April 20th, to try to ensure having some blooms for all the shows from the middle of June to the middle of July.

Climbers, hedge and shrubbery roses we prune during the winter and spring as time and weather permit. By way of conclusion remember, when pruning, you "must be cruel to be kind." The golden rules must be evolved and framed by the individual gardener in the light of the results for which he is striving.

As an artist, handling the most wonderful colours of all Nature's palette, through her most glorious medium, the rose, he can work to his end either for masses and broad effects, or for "cameos of swooning beauty," but he must not hesitate.

To the rose lover the pruning knife is more than the surgeon's lancet, cutting not to cure, but to give life and health and beauty.

Remember, too, as you use this lancet, each plant has its individuality and a separate character, which should be studied, humoured and treated for this alone. So only shall you reap the full reward of your skill and labour.

CORRESPONDENCE

ALPINES FROM THE PASS OF MONT CENIS.

RECENT articles by Mr. Lofthouse and Mr. E. Enever Todd on this subject have prompted me to reply, as the latter asks, regarding the Campanula linifolia found at Mont Cenis by the former, and he says that Flahaut gives C. linifolia as a species found in the Alps of France, and that the linifolia of Scopoli (C. carnica, Scheide) referred to by me as being found in Carinthia is an entirely different plant, though we both speak of something akin to C. rotundifolia. I have not Professor Flauhaut's small book by me, and except for the stated resemblance to the common harebell (doubtless a slip), I take it that Flahaut was speaking of C. linifolia of Lamarck as figured by the former and by Coste, and which Mr. Todd (page 73) rightly says is closely related to C. lanceolata, Lap. In my "Sub-Alpine Plants" I was more careful than in 1911 to add that C. linifolia, Scop., is not the plant of Lamarck ("*non* Lamk."), and in that volume I added Carniola to Carinthia. I now find it recorded also from Tyrol, the Trentino, Lombardy and Transylvania.

John Ball* gives "C. rotundifolia var. (C. carnica)" from his district 8: "Mont Cenis—Susa—Col de Clairée;" so it is quite possible Mr. Lofthouse found the same thing higher than Ball at Mont Cenis; or he may be referring to *C. linifolia*, Hake, which is given in Arcangeli's "Flora Italiana" as a form of the well known C. Scheuchzeri, which does grow at Mont Cenis and resembles a large-flowered harebell. The latter has a wide distribution at high altitudes from the Pyrenees to Arctic Russia, but it is rarely seen true in gardens. Arcangeli actually places C. linifolia, Lamk. as a variety of rotundifolia and, indeed, Grenier and Godron call it "Plante intermédiaire aux C. rotundifoliæ et rhomboidalis."

It is just possible Mr. Lofthouse saw at Mont Cenis the very different Campanula described and figured by Coste ("Flore de la France") as C. linifolia, Lamk., found in the Pyrenees and other mountains of France. I gathered this species 2ft. high in woods above Vernet in the Eastern Pyrenees at 3,000ft. altitude only. My specimens have thick fusiform roots. That there has been much confusion over these campanulas is evident.

Mr. Todd's recollection of Johns' comment on the specific name rotundifolia for the harebell as being a misnomer has some, but only slight, foundation; for in the first edition of Johns' "Flowers of the Field" in two little volumes (the only edition I have at present) he said: "The specific name . . . is far from being descriptive of the leaves which accompany the flower, as they are long and narrow, but is peculiarly applicable to the root-leaves as they appear in winter or early spring, at which season Linnæus is said to have first observed them on the steps of the University of Upsal." (sic.)

It may be mentioned here that the most comprehensive account of the flora of the Mont Cenis district was written by Professor Mattirolo of Turin under the title "La Flora Segusina, 1907." No fewer than 2,203 species and 279 varieties of Phanerogams and ferns were recorded from the district of Mont Cenis and Susa by April, 1907, and in July of that year I collected 180 of these growing above 8,000ft. or 2,440m. in a decidedly confined part of the district.

Should any reader be visiting Mont Cenis in the summer, he will be doing a service if he tries to find a small glabrous rose-coloured galium in a steep ravine or gully a few hundred feet above the Hotel de la Poste, because the only specimen which I got there in 1907 and which Dr. Briquet described as a new subsp. of G. asperum was divided between the herbaria at Geneva (Conservat. Bot.), British Museum and Edinburgh.

I am glad Mr. Lofthouse recommends for the garden the violet-blue flowered Scutellaria alpina and draws attention to the brilliant colour of the Calamintha alpina. I have repeatedly encouraged the cultivation of these two beautiful plants, and in *Journ. Bot.*, 1907, 345, I pointed out how very variable in colour the scutellaria often is particularly in the Mont Cenis district.

* "On the Distribution of Plants on the S. side of the Alps." Edited by Thiselton Dyer in Trans. Linn. Soc. 1896.

One specimen was entirely a rich rose colour, with bracts of the same shade, and three large clumps had pure white flowers, all the bracts being a uniform pale green instead of the normal purplish green. Actually, the flowers vary from a light mauve or lilac through every shade of purple to a deep violet.

Among the attractive flowers at Mont Cenis there was little that seems to have escaped the notice of Mr. Lofthouse, unless, perhaps, it was the dusky Swertia perennis (?). As usual, it is very local there, but a fine colony adorns a damp slope on the French side of the Pass. He mentions the two very rare British plants, Lloydia serotina and Lychnis alpina. The latter is extremely uncommon in the Alps, and I never saw it growing so well as on the Italian frontier slope referred to by your correspondent, though even there it was somewhat confined.

Reference was made to Gentiana bavarica, "one of the most difficult moraine plants occurring here in very boggy ground." Actually, this superb and very common alpine gentian is hardly a plant for the moraine, for in nature it almost always thrives best in wet, boggy ground among plenty of short vegetation, but not among stones or gravel. On page 662, "G. bavarica, or more possibly its higher form, G. imbricata," was growing "on the moraine thrown up between two torrent beds," whereas "true G. bavarica was fairly plentiful down at the Mont Cenis Lake." That's just the difference! In the swamp by the Lake G. bavarica grows in the company of Carex microglochin, which was discovered last year in Scotland and is a species new to the British Isles.

The fine spikes of Campanula spicata I, unfortunately, did not see at Cenis. Might it not be more correct to speak of this as biennial than annual? The form of Silene acaulis with large flowers on lengthy stems and with a looser habit is the variety elongata *DC.* (S. elongata, Bellardi), and I think this was an extension eastward of its known distribution when I found it in the ravine above the Hotel de la Poste. I regret to read that this glorious hunting ground among the mountains is still desecrated on Sundays (or on any day) by motor enthusiasts from Susa. But we Britishers "must not cast stones"; nay, not even from the top of Cheddar Cliffs!—H. STUART THOMPSON.

CROCUS IMPERATI.

THIS charming crocus, the earliest of the race, is in full bloom early in February, and even here in Scotland flowers have often appeared on New Year's Day. Although a native of southern Italy, it is quite hardy, and seems to enjoy the light soil of the rock garden, where it blooms freely and increases fairly rapidly.

The photograph, taken on February 7th while the sky was overcast, shows the flower closed, and displays to advantage the beautiful feathery markings on the back of the outer petals; these three delicate veins are purple, and form a pleasant contrast to their soft buff-coloured background. The flowers, when opened wide, display their lovely lilac-purple lining and brilliant orange anthers. Crocus Imperati ought to be in every garden where early flowers are appreciated; its beauty, hardiness and delicate fragrance should ensure its welcome; and, as a further recommendation, its cost is moderate.—I. S. T.

THE BEAUTIFUL COROLLAS WITH THEIR FEATHERY MARKINGS OF C. IMPERATI.

PREPARED HYACINTHS.

FROM communications received, the article on "Prepared Hyacinths," which appeared in THE GARDEN for January 12th, has created considerable interest. A friend in Holland has written to say that although the experiment of sending bulbs to the south of France was tried when "preparing" was a new thing, no Dutch firms send any there now. They "prepare" their own. There are, it is true, firms in the south of France who offer much the same thing, but from lists which I have been permitted to see their bulbs are considerably dearer than those grown and prepared in Holland. The treatment of the bulbs in preparing will surprise many. No one in cold blood would imagine it would bring about the desired result. About six weeks before the usual time of ripening and while the foliage is still green, the bulbs are lifted and, when partly dried, are then put into a high temperature of between 70° and 80° Fahr. for five or six weeks to finish them off. This is, in a nutshell, the system of preparing. It was found out by mere chance. Some hyacinths which were planted in a hot, dry corner of a Dutch nursery were observed to dry off every year earlier than the others, and in the following spring to start growth and flower sooner than others. Experiments then took place after this hint, and finally the system described above was found out. As practice makes perfect, year by year the system has been organised, so that anyone buying "prepared" hyacinths now from reputable firms may be sure that they will flower at the time which is stated in the dealers' lists. It is up to the dealers to make it quite plain which are the hyacinths which are "prepared" and which are those ripened in the old ordinary way. I know from letters received that mistakes are made by purchasers. Cynthella hyacinths, except "*prepared*" *Cynthellas*, will not bloom earlier than ordinary hyacinths. "Prepared" are what should be asked for if flowers are wanted at Christmas time. Of course, larger-sized hyacinths do equally well if they have been "prepared"; but modern taste is, I feel, all in favour of the more graceful Cynthellas. For those who can command sufficient heat there is no need to bring the pots into a greenhouse as early as I do. If a bottom heat of about 70° Fahr. and an air temperature between 70° and 80° Fahr. can be continuously given, the pots may remain outside until the third week in November and good results be obtained for Christmas. I cannot give this heat in my houses, so I bring the bulbs in about a month earlier and put them on staging which is over the hot-water pipes, which is my best substitute for "bottom" heat.

I hope that this letter will supply the necessary information.—JOSEPH JACOB.

NOTES FROM CONTRIBUTORS

KING ALFRED DAFFODIL.

MANY have seen in past springs Carter's exhibits of this magnificent daffodil in mass formation. Some have bought, have had one glorious display, have hoped for even better things the next season, but, when that time has come, have experienced a great disappointment. Wiser people have sighed, and asked the man in charge if he sold any Cornish atmosphere to go with them, as without it, or one very similar, King Alfreds were useless. The truth is, this fine variety is fastidious. I have tried lots of dodges in times past to get it to grow out of doors, but all in vain. In 1920 I had two bulbs sent as a present, and I resolved to try my luck with them in pots in a cool greenhouse. The result is three 7in. pots full of healthy foliage and buds. Usually, daffodils after they have flowered have been put in some odd corner outside to finish their growth. My King Alfreds have always remained under glass all through their life cycle, from their being potted until potting time has come again. This I believe to be the secret of our success. Although it has been in commerce so long, it is still an expensive daffodil to buy and throw away as soon as it has flowered. Hence this note of its behaviour at Whitewell may be of use to others who cannot grow it in the ordinary way out of doors as they grow Emperor, White Lady or Barrii conspicuus, but who are able to devote a small space under glass for a few potfuls.—JOSEPH JACOB.

ABORTIVE BUDS OF AMARYLLIS BELLADONNA.

AT this time of year, when the young foliage of the belladonna lily is coming up strongly, one often finds a number of abortive flower-buds being pushed up also. These are evidently buds which would have produced flowers at the normal flowering season (September) had the weather conditions not been unfavourable at that time. To produce a really generous harvest of blossom two factors are essential. First, a thorough ripening of the dormant bulbs in June and July; and, secondly, a period of mild sunny weather in September, when the flower-buds should be just pushing through the soil. If the first factor is lacking, no buds will be formed at all; if the ground becomes sodden and cold before the buds have come through they cannot develop properly and appear only with the leaves in early spring in the form of abortions. After a good flowering year (such as 1921) very few, if any, of these abortive buds appeared in the following spring, but there are always a number after a poor flowering season (such as 1922 and 1923). Last summer was remarkable for the short period of intensely hot weather early in July; this was sufficient to ripen the bulbs thoroughly, but it was succeeded by a long period of such dull sunless weather that very few buds had the strength to complete their development, hence the number of abortions seen now. However, in those gardens where the belladonna lilies had been planted in the ideal situation—a narrow border alongside a greenhouse with hot-water pipes behind them—they flowered magnificently several weeks earlier than bulbs of the same variety planted at the foot of garden walls either with southern or eastern aspects. The books always lay stress on the importance of planting the bulbs very deep, but one wonders if this is really advisable. If the top of the bulb is only 3ins. below the surface of the soil instead of 6ins. or 8ins., it would surely receive much more warmth from the sun's rays and be better fitted to develop a normal flower-stem. Deep planting may be essential in cold districts, but the belladonna lily is rarely injured by frost in the south and west of England. In Guernsey it flowers profusely in open borders and the bulbs are sometimes left to form huge clumps with their tops barely covered by the soil. A certain amount of moisture at the roots at flowering time is no doubt advisable (this usually coincides with the autumn rains), but I doubt if it is desirable to water the ground until some of the buds are seen to be pushing their way through. Anything in the nature of chilling the soil is harmful to the welfare of this lover of sunshine and warmth. After all, there are not many plants native of the West Indies which adapt themselves to our fickle climate at all, so that we cannot reasonably expect a rich harvest of flowers after a particularly cheerless summer. It is, however, little consolation to the gardener to observe a fine crop of abortive buds in spring instead of the noble sheaves of flowers of which an inclement autumn has deprived him.—NORMAN G. HADDEN.

TWO PRIMULAS NOTED AT GLASNEVIN.

AN uncommon Primula is P. Dubernardiana. It has bright green markedly reticulated leaves with long petiole and ovate lanceolate blade 2½ins. long, lightly golden underneath. Its flowers are as large as those of the wild primrose, tufty in growth, pale pink colour with a well marked yellow eye. It flowers in the alpine house in early January and is an introduction from China.

Primula verticillata is a distinct variety from Copenhagen, well worthy of cultivation. Its flowers, smaller than the type, are a good yellow colour, the leaves are almost obovate, powdered mealy white. It is a more compact grower than the P. verticillata usually seen and is altogether a charming little plant for the alpine house early in the year.—W. P. MOORE.

DEINANTHE CŒRULEA.

THIS rare and beautiful plant which, I suppose, is still on its trial in cultivation, is one of the most distinctive of recent introductions. D. cœrulea is a near relative of the saxifrages, an herbaceous perennial which puts up in spring stout, fleshy stems and deeply-lobed large leaves with a reddish tinge suggesting those of a tuberous begonia. The foliage, rather more than a foot in height, is crisp and crinkly and each leaf is surrounded by a fringe of dark bristles. In early summer if not before, the round, red buds which appear in clusters, terminating the above growths, open into blooms of singular loveliness that have been likened to a blend of auricula and shortia. But the fact is they are to the untutored eye, as they are to the botanist, quite unlike anything else. As to the colour of these soft-textured blooms it is a clear smoke-blue deepened by a hint of palest violet, a tone that is inexpressibly charming in shade or subdued light.

D. cœrulea, I am informed, was first found by Henry at Hingshau, but it is to Mr. E. H. Wilson that we are indebted for its introduction. He sent over some seed from Hupeh and the late Mr. Elwes raised and flowered a few plants at Colesborne in the summer of 1909. Two years later the species was figured and described in the *Botanical Magazine*.

Whether D. cœrulea is perfectly hardy there has been some doubt, but it has withstood some fairly severe frosts with us. That it resents excessive wet in winter is evident, but otherwise its culture appears to offer no difficulty. It seems to enjoy shade, ample moisture in spring and summer and a well drained root-run in a peaty or good vegetable mould freely mixed through with sand and stones.—A. T. JOHNSON.

LENTEN ROSES

LOVERS of hardy plants find it passing strange that the beautiful Lenten roses should be so little grown in the majority of gardens. Flowering at a season when any outdoor bloom is precious, their absolute hardiness and ease of culture, with their handsome deep green foliage and graceful habit, they seem to be ideal plants for every garden in the land. The much more fastidious Christmas rose is far more often grown and sometimes treated to an overhead light to keep its flowers clean and unsoiled by storms; yet the Lenten roses, in their great variety of colour and with their simple tastes, are constantly neglected. Like all the hellebores, the Lenten roses are deep-rooting, hungry plants, hence they demand liberal treatment and a well dug soil when first planted. An annual mulch of old manure will result in extra strong growth and finer flowers, though this must be regarded more as a luxury than a necessary item of their culture. Being natives of woodland, they succeed best in somewhat shady situations and are liable to droop badly during a drought if exposed to direct sunshine. A sheltered position is preferable, since their early flowering season generally coincides with stormy weather, which is liable to damage the tender young foliage. They flourish with equal vigour in mild Cornish gardens and on the east coast of Scotland: in the south they begin to flower before January is out, but in cold districts their name of "Lenten rose" is more appropriate. They will tolerate a heavy clay soil and a hungry sand, but a rich deep loam naturally suits their vigorous root system best of all. They are excellent subjects for naturalising in thin woodland or in nut groves or in old orchards. They thrive among deciduous shrubs and are very useful for north borders in small gardens. In some places mice are said to be in the habit of eating the young buds—a peculiar taste, as all the hellebores are exceedingly poisonous; slugs do not trouble them, although they often gnaw the buds of Christmas roses.

Several distinct species of Helleborus are generally known as Lenten roses, the chief of which are H. orientalis (rosy-purple with numerous deeper spots) and H. guttatus (large white with purple spots). These two species hybridise freely and give rise to many intermediate forms, some pale rose seedlings with only a few spots at the base of the flower are especially attractive. H. olympicus (white), H. colchicus (deep purple), H. abschasicus (greenish white) and H. atrorubens (rosy-purple) are other species often offered in catalogues but not always easy to obtain true to name; they all interbreed readily, consequently many seedlings of more or less doubtful merit make their appearance from time to time.

The late Mr. Archer Hind of Newton Abbot worked for many years at improving the Lenten roses and raised many very fine varieties. What has become of these now? There still seems to be ample scope for further experiments in crossing the various species and in selecting the best seedlings. The seed is not long-lived and should be sown soon after it is ripe; it will then germinate well the following spring and the seedlings may be pricked out in a shady border. They mostly flower in their third season, so that the raiser has not

Digitized by Google

much time to wait before seeing the results of his labour.

Lenten roses may be divided either in spring or autumn when it is desired to increase some particular variety; they do not take so long to recover from division as the Christmas roses, but are not at their best for two or three seasons, hence the value of having a stock of healthy young seedlings. Seedlings may often be found self-sown near old-established clumps and can readily be moved to fresh quarters. Unless they show signs of deterioration the old clumps should be left for a number of years and will annually yield quantities of flowers which are most useful for cutting.

It is well known that the flowers must have their stems split longitudinally when put in water or they will droop at once and not recover. Immersion up to the neck in water for a night before arranging them is recommended in the R.H.S. Gardener's Diary. Frequent changing of the water in the vases greatly adds to their length of life, and when this is attended to daily they will last in beauty for a fortnight or more.—"SOMERSET."

MODERN GREENHOUSE CONSTRUCTION AND HEATING

BY GEORGE GARNER.

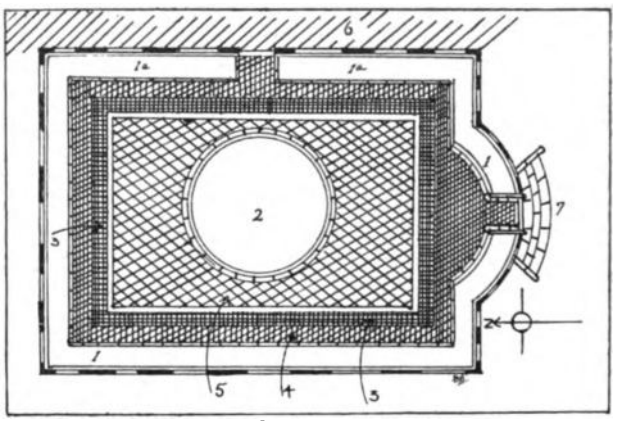
FIFTY years ago the majority of the structures for plant and fruit growing were of the lean-to type. Wood was plentiful and not expensive, but glass was scarce and cost more. Thus our fathers and grandfathers were very proud of possessing a single lean-to greenhouse, which generally contained a miscellaneous collection of plants, some of which we now regard as sufficiently hardy to remain in open borders the whole year round. The timber of these old structures was good and bulky, the glass poor, and the squares small.

The modern idea is to have light and airy structures built of well seasoned wood and reinforced with iron rods. Ventilation, too, is more abundant, the air being admitted freely at the will of the cultivator and usually without causing unnecessary chills to the plants. There are exceptions, of course, but the rule is, in these times, to build plain structures for purely utilitarian purposes; but our horticultural builders are capable of erecting more ornate and imposing structures when it is a question of adding a conservatory to the dwelling-house, and one that shall add to the beauty of the latter.

Perhaps the greatest advance has been made in the application of artificial heat. In the olden days brick flues were the only means of ensuring sufficient heat in the house to expel frosts, and much labour was entailed in keeping the internal temperature even and high enough for the purpose. Now we possess magnificent heating apparatus capable of maintaining an even temperature, varying in degree, as required, in quite a large number of modern structures at a minimum cost both as regards fuel and labour. The single and more modest greenhouse may also be heated in the simplest way and as effectually. Overhead hot-water and steam pipes are used in many structures where it is necessary to force hard or to preserve from damp the delicate flowers of some of our plants, especially during the autumn and winter months.

ABOUT BOILERS.—The plain saddle boiler was, not many years ago, commonly used and highly appreciated; soon the check-end saddle replaced it to a great extent, and in rapid succession our manufacturers and engineers placed on the market more powerful boilers and also miniature ones to heat small structures. These small boilers have been a great boon to amateurs who possess little greenhouses and conservatories and, furthermore, create a big demand for the erection of such houses.

The large sectional boilers, suitable for nurseries and large blocks of glass houses generally, need stokeholds, but they can be fixed without a mass of brickwork and brick-flues. They are as easily managed as the smaller ones. Wrought-welded boilers are very powerful and favoured by many cultivators. With ordinary care these boilers will last a generation in good working condition when used for forcing houses.

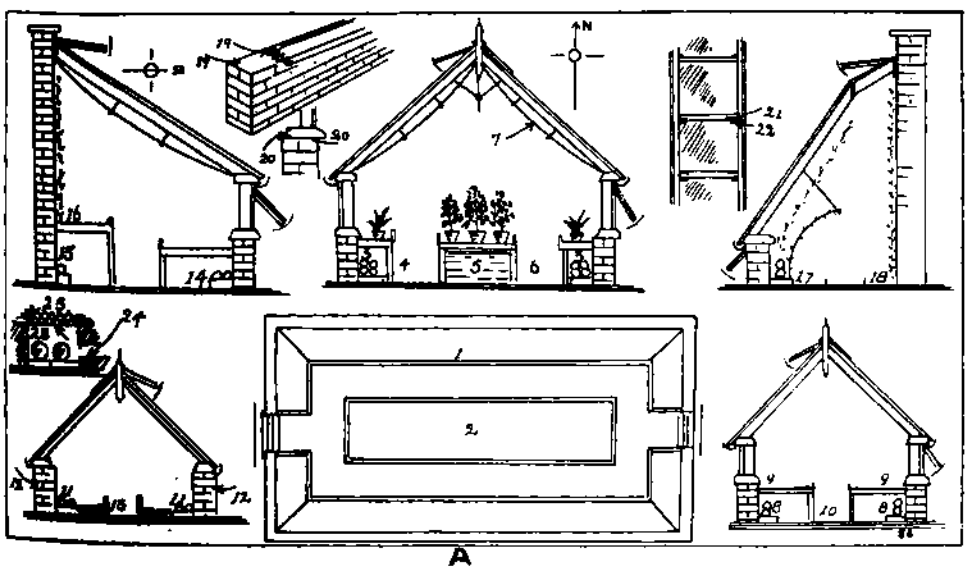


R

ILLUSTRATING THE GROUND PLAN OF A CONSERVATORY.

THE TENANT'S FIXTURE BOILER.—This type is made in various forms. One, upright in shape, may be placed in a tiny shed adjoining the greenhouse, free of all brickwork, the smoke-pipe being carried through the roof of the shed. The hot-water pipes, flow and return, pass through the wall and are fed through feed-box, water expansion box at the extreme end of the pipes farthest from the boiler. The air escape pipe is also placed at this point. Injurious fumes from the boiler furnace cannot enter the greenhouse. Special fittings are not required.

Another form of small boiler is one that is fixed in the end of the wall of the greenhouse, the front being flush with the face of the outside wall and the smoke-pipe is carried up clear of the structure. With these boilers there is little danger of flooding where water is always near the surface, as the stokehold rarely exceeds 18ins. in depth, just sufficient for the ashes. Where room for a covering shed is not available, such shed is not absolutely necessary. The greater part of the boiler is inside the greenhouse and the heat from it is equal to 10ft. of 4in. piping.



A

PLAN AND SECTIONS OF DIFFERENT TYPES OF GREENHOUSES.

Digitized by Google

One such boiler measuring 2ft. in height, 1ft. 2ins. in width, with a depth of 1ft. will heat a 70ft. run of 4in. piping—flow and return. The stoking is done outside, the feeding at the return point—the expansion box. This is another tenant's fixture, special fittings are not needed, and the furnace will consume cinders and all kind of rubbish from the dwelling-room grates. Banking-up may be done at eight o'clock in the evening, and the fire and temperature will be normal at eight o'clock the following morning.

GAS AND OIL BOILERS.—These one may term midgets, yet they are powerful and most useful. The gas-heated boilers are capable of heating not only small but fairly large greenhouses, local situations being convenient for the fixture of boiler. The oil-heated pipes maintain an even temperature, are easily regulated and the combustion is good. The whole apparatus is in the greenhouse itself, but may be taken in or out at will.

The following are some of the essential points that should be duly considered by cultivators who wish to erect and heat new houses.

THE SITE.—A fairly open position is the best, the ideal one being sheltered from strong winds but not overshadowed by tall buildings or trees. The shade required should be applied at the will of the cultivator. But it is not always possible to make a selection of positions; also, there are exceptions, for instance, where it is intended to grow palms, ferns and other shade-loving plants; then there are many sites near the dwelling-house itself suitable for the structures. If the subsoil is naturally wet, then pipe drainage is advisable.

THE FOUNDATIONS AND WALLS.—Even the smallest greenhouse should have a sound foundation. A large one should be built on a concrete base whether the walls be of bricks or stones. The regulation height of the walls above ground level is 2ft. 6ins., and the height of the front woodwork and glass 2ft. 6ins. also—5ft. to eaves. Five feet is a good useful height, but it may be varied according to requirements.

WOOD AND IRON.—All wood used should be sound and thoroughly seasoned. The sash-bars of large houses are rarely made of thick deep pieces, but of comparatively small ones, and about every fourth bar is a little stronger, these being reinforced with iron bars shown in the accompanying sketches and referred to later on in this article. The more slender bars are supported and strengthened by fixing angle-irons transversely and securing the bars to them with screws. Lantern roofs are ornamental, useful and imposing, being very suitable for some kinds of structures, but they add expense to the building account.

In olden days the wall-plates were embedded in mortar. When these old houses have been repaired it has been found that the undersides were dry-rotted. In the case of modern structures the wall-plates are laid on the dry wall and the joints on both sides duly cemented. Iron frames are employed in many instances for supporting the staging wood where the latter is used. Slates and shingle are clean, lasting and more suitable for some kinds of plants.

GLASS AND GLAZING.—Twenty-one ounce glass should always be used for the roofs and, personally, I prefer it for sides and ends as well. The bevelled or slightly hollowed squares convey the water from the wood, forming a miniature channel down the centre when it rains. Primed wood is, usually, glazed, but it is better to apply one coat of paint in addition first. The glass should be well embedded in good putty, held securely by brass sprigs, and with no top putty. When afterwards the houses are painted, all exposed wood is covered and there is no risk of wood rotting under loosened top putty.

THE ILLUSTRATIONS EXPLAINED.—In Fig. A, Nos. 1 and 2 denote the plan of staging in a span-roofed greenhouse. The section of this house is shown on page 133. Nos. 3, 3, two flow and two return hot-water pipes; No. 4, side stages; No. 5, central stage, also answering as a cistern to contain rainwater from the structure; No. 6, paths. No. 7 shows the strengthening rod to roof bars. Roof angle 45°.

If all staging be removed, a house of this kind could be used as a vinery. The heating then would be as follows: Two flows at the sides respectively and one return down centre of bed and one on each side of the central path. The narrower span-roofed house is heated as shown at Nos. 8, 8; flow and return on each side; stages, Nos. 9, 9; path, No. 10. These are most useful houses for bringing on young stock for furnishing the conservatory or dwelling-house.

The forcing greenhouse may be built without stages. The hot-water pipes are shown at Nos. 11, 11; air being admitted at the sides, Nos. 12, 12; path, No. 13. In this house heat is conserved, and melons, cucumbers and young stove plants usually grow well in them. Roof pitch for these two houses, 45°.

No. 14 shows flow pipes; No. 15, one return hot-water pipe in a lean-to. The back stage, No. 16, may be used, or removed and a border for climbers take its place. The roof pitch is not quite 45° and needs the strengthening iron rods. The aspect is due south.

The economical fruit structure is shown with front and back borders, Nos. 17 and 18 respectively. The roof angle is 60°, and does not need any strengthening iron rods. The various ways of training fruit trees or, it may be, roses, etc., are shown.

Nos. 19, 19, 20, 20, show how the wall-plate is placed on the wall, the joints cemented, and inside the house the cement is shown so placed in position that water does not lodge there. No. 20, left-hand side of sketch.

No. 21 shows the brass sprigs holding a square of glass firmly to sash-bar, and No. 22 sprigs fixed so as to prevent the square slipping down. The nails, when driven in, hardly show and are painted.

Winter gardens and many conservatories are heated by laying pipes in a trench under the path or floor. When this system is adopted some pipes should be laid (one, two or three, according to size of house) to allow fresh air to enter the trench and drive out the heat from the hot-water pipes. Without these fresh-air pipes there would be loss of heat. No. 23 shows pipes in trench; No. 24, fresh-air pipe; No. 25, iron grating.

Fig. B shows the ground plan of a conservatory or winter garden. Nos. 1, 1, side stages; Nos. 1a, 1a, stages or border against wall of dwelling-house, either for pot plants or climbers. A central bed is shown at No. 2; Nos. 3, 3, iron grating over hot-water pipes; No. 4, small tiles; No. 5, larger tiles; No. 6, the dwelling-house; No. 7, steps to entrance to conservatory.

STRAWBERRIES

I HAVE never seen strawberry plants more robust than they are this year. There is good promise of a good crop of fruit if the blossom is not damaged by frosts. Although the plants are cleared of all runners in late summer or early autumn, there are, generally, quite a large quantity of late-grown runners and weeds to be found at this season and they should be cut off and hoed up respectively so that a substantial dressing of strawy manure can be applied forthwith. Having thoroughly cleaned the ground, the weeds that grow later should be pulled up by hand so as not to disturb the layer of straw around the plants. The rains and weather generally settle down the littery manure firmly, and wash the straw portion clean; thus it forms a suitable bed for the ripe fruits. In the absence of such surface dressings, straw or litter will be needed in due course. The fruits should be protected from the birds by fixing nets over them. Perhaps my method of doing this will be of interest to some cultivators. Strong sticks are driven into the ground 9ft. apart in rows 5ft. asunder and 2ft. 6ins. above the ground. All the outer sticks are set at an angle of a few degrees away from the bed itself so that they will bear the strain of the nets placed over them. The nets are then pegged to the ground all round. Wires are fastened to these sticks and a small wisp of hay or straw is tied tightly to the top of each stick, thus allowing the nets to be put on or pulled off without catching in any uneven part of the stick. It is economical to get these stakes and wires fixed forthwith, or as soon as possible, so that the nets can be drawn over the strawberry bed every night while the plants are flowering and so, probably, save much blossom from destruction. In this way the nets serve a double purpose and the good results warrant the little trouble entailed. HANTS.

FORTHCOMING EVENTS.

March 1.—Fête to be held under the auspices of the Horticultural College, Swanley, Kent.

March 4.—Croydon Horticultural Society's Meeting.—Royal Caledonian Horticultural Society's Meeting.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbages are always useful, and a liberal sowing of a suitable kind should be made with a view of having plants at hand to fill up spaces as other crops are cleared. Both Imperial and Favourite are reliable varieties, and the seeds should be sown thinly in lines 1ft. apart.

Broccoli.—Autumn broccoli should be sown about this date, and the seedlings transplanted in a good piece of the garden in lines about 2ft. apart. Firm ground is essential. Suitable varieties are Michaelmas White, Autumn Protecting, and Self-Protecting Autumn.

Globe Artichokes.—If these have been protected during the winter months, the material may now be removed. Globe artichokes can be raised from seeds sown during the present month, but the usual procedure is to increase the stock by suckers which are obtained from the old plants. New plantations may be made next month, but in the meantime prepare the ground, first giving it a liberal dressing of manure.

THE FLOWER GARDEN.

Scabiosa caucasica.—Of late years a great improvement has been brought about in this beautiful plant, and now there are quite a number of distinct varieties. No flower garden can afford to be without them, and where difficulty in growing them is experienced, the chief cause will be slugs or the absence of sufficient lime in the soil. An open, well-drained site is essential, and the best time to plant or divide is during the month of March. Slugs are most troublesome in winter, and only a liberal application of lime will hold this pest in check. S. caucasica is a perennial, quite hardy, and will need dividing every second or third year. Messrs. Isaac House of Bristol have brought out several varieties of outstanding merit. Seeds are also offered, and this is a good method of increasing the stock; but the varieties do not reproduce themselves true from seed. However, some useful forms may reasonably be expected, and, moreover, all would be of value for cutting purposes. Seedlings can be raised in a warm greenhouse, gradually hardened off, and planted out in June.

Buddleias.—The various forms of B. variabilis should be pruned forthwith, cutting last year's growths back to two or three eyes. Hard pruning is essential if really fine sprays of blooms are needed, and unless such pruning is carried out annually the plants become crowded and take up a lot of space.

THE HARDY FRUIT GARDEN.

Protection of Fruit-blossom.—A difference of opinion exists as to whether it is really necessary to protect fruit-blossoms at this period of the year, but where wall trees are about to open their flowers and there is a likelihood of frosty nights, I think it is worth while to protect the flowers as much as possible. Heavy thick coverings are not advised, neither should they be permanent, but of such a nature so that the material used can be readily and easily removed without injury to the blossoms. Thin tiffany or canvas will be found suitable, and if it can be arranged so that it may be rolled up during the day it will be an advantage. A double thickness of fish netting will also keep off a little frost, and this need not be removed during the day. Apricots, peaches and nectarines are among the earlier-flowering fruit trees.

Nets.—During wet weather all netting should be looked over and, where it is possible, repaired with thin tar twine. If new netting is needed this season, the order should soon be given.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Parsnips.—Deeply cultivated ground is necessary for the successful cultivation of this root vegetable. If pegs were put in to indicate where the celery trenches had been, parsnips may be grown there. To obtain long, straight roots, make holes with a large dibber two or more feet deep in lines 18ins. apart and 12ins. or 15ins. distant from each other. Fill the holes with good fine potting soil. In each sow a few seeds and cover with ½in. of fine soil. When thinning out the seedlings leave the best placed plant to occupy each hole. Lisbonnais and The Student are good varieties.

Salsafy is another root vegetable which should have an open position and deeply worked ground, and may be grown on the same section of land as parsnips. Salsafy should receive somewhat similar cultural details as the above. Sandwich Island Mammoth is the variety usually grown.

Spinach.—The green leaves of this plant are used in cooking, therefore it behoves the cultivator to have rich and well tilled soil on which to grow the plants. Take out rows 1in. or 2ins. deep and 1ft. apart, and sow now the round-seeded or summer spinach, and thereafter as requirements demand. It is customary to sow spinach between the lines of culinary peas, and good crops may be obtained from such positions.

THE FLOWER GARDEN.

General Work.—Fork over herbaceous borders and pick out all underground stems of perennial weeds. Clip holly hedges and ivy on chains and walls. Weed among plants in frames and pinch out the tops of calceolarias and, except when frosty, allow the plants plenty of air.

Saxifraga umbrosa.—This well known hardy plant is very effective when in bloom, and is excellent when used as an edging where standard roses are grown. It is not over-particular as to situation, but where the soil is good it spreads rapidly. Where overgrown it should be lifted now, divided and replanted.

Seeds to Sow.—Several kinds of half-hardy annuals should be raised in heat and, although kept under glass until set out, they should be grown as hardy as possible when once established. The following should be sown now: African marigolds, alonsoa, asters, cosmea, nemesia, nicotiana, ten-week stocks, etc., and others like Dianthus Heddewigii and larkspurs may be grown under the same conditions.

Sweet Peas.—If sufficient plants have not been raised under glass in boxes and pots to meet requirements, an opportunity should now be taken to sow out of doors when the ground is fairly dry and workable.

FRUITS UNDER GLASS.

Melons.—Where it is not yet convenient to make a bed in a pit or on a bench, accommodate the plants in large pots and keep them growing in a warm, moist atmosphere.

Strawberries.—A batch may be brought into one of the vineries or even a peach house provided there is shelving accommodation and plenty of light. Plants should now be showing their embryo flower trusses.

Trees in Flower.—Apricot and pear trees coming into flower should be allowed plenty of air; it is also wise to use the rabbit's tail among the blooms.

Vines.—The flowers should be expanding in the early house, and a somewhat drier atmosphere should be maintained and top air given freely on all favourable occasions.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Hæmanthus Katherinæ. — This fine "spider lily" is deserving of more general cultivation for the conservatory and greenhouse. The hybrids Andromeda and King Albert are also equally useful. Plants that have been kept dry all the winter should now be showing signs of growth. They should be placed in a house with a temperature of 50° to 55°, giving them a good soaking of water at the root. Large, established specimens in good condition at the root will require no further attention beyond the removal of some of the top soil, replacing it with a top-dressing of a good potting compost. Young plants when they have commenced to grow should, as they require it, have a shift into larger pots, while plants in bad condition at the root should be shaken out and washed, carefully removing all dead roots and decaying matter from the base of the bulbs. After repotting, water should be very carefully afforded until the plants have made some growth and a quantity of new roots. This last remark applies to all newly potted bulbous plants. More plants of this class are spoiled at this stage by overwatering than from any other cause. H. Katherinæ grows and flowers freely when planted out in a border in a warm greenhouse. This species is a native of Natal, as also is HH. insignis and natalensis. The latter succeed under the same treatment. The Cape of Good Hope species, which includes HH. puniceus, sanguineus, tigrinus and albiflos, all succeed under cool greenhouse conditions and, like so many South African bulbous plants, their growing and flowering season is during our winter and spring. These plants, therefore, go to rest during our summer, starting into growth during the autumn. Bearing these facts in mind, their successful cultivation should present no difficulty to anyone with a greenhouse and cold frames.

Erythrina Crista-galli. — Where old plants have been stored dry for the winter they should now be brought into a cool greenhouse and given a good soaking of water at the roots. This fine plant is easily raised from seed or by means of cuttings, selecting for the latter purpose some of the more slender young growths. When they are about three inches in length they root readily in a case with slight bottom heat at command. Young plants will not stand drying off like old ones with a large woody root-stock, thus for several winters they require occasional attention as regards watering.

Freesias.—It is not generally realised how easy it is to grow freesias successfully from seed. If seed is sown this month, the resultant plants should flower during November. However, the coloured varieties are more uncertain, many of them taking longer to flower. The seed should be sown directly into 48-sized pots, in which the plants should be allowed to flower. Thin out the seedlings to nine or ten in a pot. While the seed may be germinated in a warm house, subsequent cultivation should be carried out in a cool, airy greenhouse or cold frame, keeping the plants well up to the roof glass.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Seakale for the Flower Garden (E. L. H.).—The seakale recommended for planting in flower borders for the sake of the handsome glaucous foliage is the ordinary seakale as commonly used in the kitchen garden (Crambe maritima). It is worth noting when the flower stem is thrown up and the flower buds are showing that it can be used as a vegetable cut as broccoli. This applies chiefly to an old plants that may be about the kitchen garden, for when it is used in the border the flowering stems had better be cut out as soon as they appear, so as to let all the strength of the plant go to the foliage.

THE GREENHOUSE.

Propagating Echeverias (A. H.).—Most echeverias are readily propagated by means of seeds sown in heat in spring. Some produce offsets, which afford a ready means of increase. With those species from which no offsets are developed, and from which no cuttings can be obtained, recourse must be had to the leaves. The leaves should be pulled—not cut—off in autumn, laid on dried sand in pans on a shelf in a propagating or other warm house and not watered. After some time small plants form at the ends of the leaves: these should be carefully watered and as soon as large enough to handle potted up in sandy soil. The arborescent kinds may be increased by means of cuttings during the summer months.

TREES AND SHRUBS.

Pruning Clematises (R. S.).—C. Jackmanni thrives best when fairly hard pruned in February or March each year. Last year's growths should be cut back to half their present length and even more than this in proportion can be cut off when the plant in later years has increased considerably in size. C. montana should not be pruned until after flowering, as the dainty white blossoms are produced on the shoots made last summer. For a year or two only the thin ends of the shoots and cross pieces should be cut out, as our correspondent's plants have only been in position two years. When older and much larger a considerable amount of the old flowering wood may be cut out as soon as the blossoms fade.

Holly Tree Unsatisfactory (A. R.).—We are unable to find any definite cause for the damage to the holly shoots. The work looks like that of a beetle, but no beetle is known to attack hollies in this way. Birds may have started the trouble, but in any case there does not appear to be sufficient grounds for destroying the trees. If any animal is seen to cause the trouble, we should be glad to have particulars.

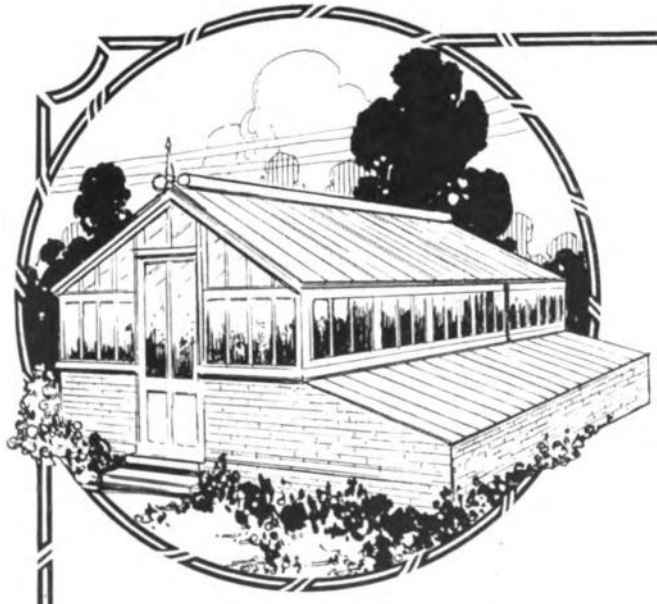
MISCELLANEOUS.

Names of Plants.—L. B. W.—Cestrum fasciculatum.——G. A.—Solanum aculeatissimum.——N. G. W.—Iris unguicularis (I. stylosa).

Name of Fruit.—"Dorset."—Apple Dummelow's Seedling (syn. Duke of Wellington).

Forestry at Wembley.—A village hall, a house and a pavilion built of home-grown timbers and containing every manner of wooden article made in Great Britain will form an important forestry exhibit at the British Empire Exhibition at Wembley. It is being organised by a Timber and Forest Products Committee, with Lord Lovat as its chairman and Mr. W. Dallimore of the Royal Botanic Gardens, Kew, as secretary. The village hall will be built of Scottish pine and larch. It will be 70ft. long and 20ft. wide. The other house will show the uses of English oak in a half-timbered fifteenth century house in which 5,000ft. of oak will be used. The pavilion will be erected solely from English hard woods. Inside these structures will be placed exhibits of wonderful variety, such as fittings and furnishings from Caledonian woods, furniture, kitchen utensils, dairy implements, tool shafts, spokes, felloes and naves of wheels, brush backs and other things made from English hard stock. Outside in the gardens there will be young trees shown by Scottish nurserymen. The development of the various woods will be on exhibit by the Forestry Commission. Visitors will see everything from setting and seedling, splitting and sawing down to ships, baulks and giant beams. The Exhibition's forestry section will be of great value in a time of house shortage and lack of materials. It will indicate how the ancient craft of forestry can best be revived.

Grand Yorkshire Flower Show and Gala.—We understand that after much difficulty a site has been found at Fulfordgate, York, which is quite near to the city and well served by trams, etc. The show will be held on June 18th, 19th, and 20th. Schedules may be obtained from Arthur Anderson, The Assembly Rooms, York.



First—from the first

WHEN the designing and building of Glass Houses became an industry—when purchasers realised that a Glass House was something more than a combination of glass, woodwork, and bricks—Duncan Tucker & Sons, Ltd., were the first to apply their practical building experience to the problem of efficient Glass House construction.

This was many years ago — since then Duncan Tucker & Sons, Ltd., have steadily progressed, and their structures are to be seen in every part of the country. In spite of increased competition they still hold the proud position of being the largest builders of Glass Houses in Great Britain. Whether you are contemplating the renovation of an existing Glass House, or the erection of a new one, this experience is yours for the asking.

¶ Those contemplating the erection of a new Glass House are invited to send for a free copy of an illustrated Brochure entitled "The Charm of Perpetual Summer." This Book, handsomely illustrated from actual photographs, contains much useful information relating to the design of Glass Houses for specific purposes, and their upkeep.

Barr's Choice Flower Seeds

A Few Novelties and Specialities for 1924.

	Pkt. s. d.
ANCHUSA Italica Lissadell, a beautiful border plant producing large flowers of a *clear Gentian-blue*, h.p., 5ft.	2 6
ANTIRRHINUM. New Giant Strain. Flowers of wonderful size, plants of tall and vigorous growth.	
Copper King, flowers *rich blood-crimson* with *fiery red* lip, very showy and attractive, 3ft.	1 6
The Rose, a very charming colour, beautiful *old rose* with *yellow* lip, 3ft.	1 6
Mixed Colours, containing many varied and beautiful colours; splendid border plants, 3ft. **1s. 6.** &	2 6
AQUILEGIA, Barr's New Rose and Scarlet Shades, *extra selected strain*, very beautiful large flowers, mostly with long spurs, colours *rose-scarlet* and *rose* to *amaranth-pink* with *white* or *yellow* corolla, h.p., 2ft. **1s. 6d.** &	2 6
CALENDULA ORANGE KING, Barr's Extra Selected Strain, intense glowing orange	0 6
CAMPANULA TELHAM BEAUTY, a grand variety of *C. persicifolia*, introduced by us, which at the Holland House Show on July 4th, 1916, was given the R.H.S. Award of Merit. Produces on long stems immense bell-shaped open flowers, beautiful *clear lavender-blue*, h.p. **2s. 6d.** &	3 6
CANDYTUFT, Barr's "Brilliant Gem," a remarkably effective variety with flowers of a *brilliant deep ruby rose*, a beautiful plant for flower beds and borders, h.a., 1ft.	1 0
CENTAUREA Cyanus Double "Silver Queen," a very beautiful double *white* **Cornflower** which will be highly appreciated for cutting; h.a., 2ft. For this novelty we were given an Award of Merit, R.H.S., 1922	1 0
CHRYSANTHEMUM, New Large-flowered Single Varieties, a very decorative strain producing large flowers of many varied and rich colours; valuable for borders and pots and for cutting; h.h.p., 2ft.; seedlings of February flower outdoors in July	1 0
CHRYSANTHEMUM Maximum Mayfield Giant, flowers of great size and fine form, h.p., 4ft.	1 6
DIGITALIS (Foxglove), "The Shirley," a magnificent new strain raised by the late Rev. W. Wilks; it produces plants 5ft. to 7ft. high, with spikes 4ft. long, carrying flowers of great size ranging from *white* to *dark rose*, handsomely blotched and spotted *crimson*, *maroon*, and *chocolate*, h.p. **1s.** &	2 6
ECHIUM Wildpretii, a wonderfully striking biennial plant from the Canary Islands, producing a dense rosette of silvery silky foliage, 1½ft. high, from which rises a handsome spike 2ft. or more long, crowded with *purplish pink* flowers. Good pot plant for the sunny part of a greenhouse; in the Scilly Islands it grows freely outdoors.	2 6
IMPATIENS Roylei White Queen, clusters of *snowy white* flowers, prized for cutting, and a beautiful border plant, h.a., 5ft. to 6ft. **1s.** &	2 6
LILIUM Regale, a very beautiful Chinese Lily bearing large trumpet-shaped fragrant flowers, *white* flushed *yellow*, with *ruby-red* on back of petals, hardy bulb, 3ft. to 5ft. *Flowers in two years from seed*	2 6
LUPINUS Paynei, a fine new Californian species producing massive foliage and stately branched spikes varying slightly in shades of *pink*, h.p., growing up to 6ft. and over. It can be flowered the first year from seed **1s. 6d.** &	2 6
MYOSOTIDEUM nobile, the **Giant Forget-Me-Not** of the Chatham Islands, bearing large corymbs of beautiful *blue* flowers edged *white*, 1½ft. *Very scarce*	2 6
MYOSOTIS, Barr's Alpine Blue, the richest blue of all Forget-me-nots, forming compact bushes literally covered with heads of lovely *intense deep blue* flowers, and producing a most striking effect in the flower and rock garden, h.p., 9in. **1s.** &	1 6
PAPAVER nudicaule "Pearls of Dawn," a most lovely new strain of Iceland Poppies, producing satiny crinkled flowers of delicate shades of *pink* with *orange* or *salmon* glow, *salmon shaded blush*, *orange shaded cream*, *rose shaded pink*, etc., h.h., 1ft. **1s.** &	1 6
PHORMIUM tenax, Powerscourt variety, a fine variety of the New Zealand Flax, 10ft. to 14ft.	1 6
POPPY, New Double Queen Poppies, a lovely new strain of hardy annual Poppies of the Shirley type, flowers double and semi-double, of the most delicate and brilliant colours, *white* with *salmon*, *pink* or *crimson* margin, *fiery rose-scarlet* shading to *white*, *brilliant scarlet* with *white* centre, etc., all showing *yellow* anthers, 2ft.; valuable for cutting, h.a.	1 0
POPPY, Double Munstead Cream, a beautiful Pæony-flowered annual Poppy, *chamois-rose*	1 0
SCHIZANTHUS, Dr. Badger's New Giant-flowered Hybrids, a grand strain with very large handsome flowers, measuring 1¾ to 1¾ins. across, in great variety of colours and markings, *rose* blotched *salmon-red*, etc., *ruby* blotched *maroon* and *gold*, *dark blue* blotched *maroon-purple*, etc., h.h.a., 1ft.; splendid plants for greenhouse decoration or flower border	2 6
STREPTOSOLEN, Jamesoni, a lovely cool greenhouse shrub of elegant habit, bearing corymbs of showy *brilliant orange-yellow* flowers, 3ft. to 4ft.	1 6
SWEET PEA, Beautiful New Varieties in Mixture, a wonderfully fine mixture containing some of the best newer sorts of Sweet Peas, which cannot fail to give satisfaction to buyers per oz. **2s. 6d.**	1 0
THUNBERGIA Gibsoni, a beautiful greenhouse climber, flowers brilliant *glowing orange*	2 6
VERBENA, Barr's New Giant-flowered Mixed, surpassing all other Verbenas in size of bloom and variety of colours, producing a very decorative effect in flower-beds and borders; all the flowers have a *brilliant white* eye which enhances their beauty, h.h.p., 1ft. **1s.** &	2 6

BARR'S SEED GUIDE for the most Beautiful Flowers and Best Vegetables Free on Application

BARR & SONS, 11, 12 & 13, King Street, Covent Garden, London, W.C.2

WELLS' GOLD MEDAL DELPHINIUMS AND PHLOX

All lovers of these plants should not fail to send for the following collections. All strong English grown plants, and sure to give satisfaction. They will give delight and charm in any garden.

DELPHINIUMS

Corry, double variety, sky blue, suffused with red, a splendid variety, 2/6.
COSSACK (new), bright clear blue, with bronze centre, single flowers, this has a splendid long tapering spike, quite distinct from any other variety, 2/6.
Gwen, gorgeous Cambridge blue with delicate pale mauve shadings. A most distinctive spike and flower, exceedingly pretty, 3/6.
JOAN CARTER (new), lavender mauve, white eye, semi-double flowers, a very useful variety for cut flowers, 2/6.
King of the Delphiniums, as the name suggests, is a "King" among the Larkspurs; under favourable conditions it reaches 8ft. in height. Rich gentian blue with very striking white centre, 1/6.
Lizzie, pure sky blue single flowers on tall graceful spikes, 1/6.
Mdm. Emma Zaiser, clear blue, centre petals rose, semi-double, one of the finest, 1/6.
Mary Wells, electric blue outer petals, inner petals rosy mauve with bee eye. Large semi-double pips, good graceful spike, 5ft., 3/6.
MERSTHAM GLORY (new), outer petals Cambridge blue, inner petals rosy mauve, white eye, semi-double, the best of its colour, 2/6.
Mrs. H. Kaye, rich indigo blue, flushed with light purple, large semi-double flowers; spike, light and elegant, 5ft., 5/-.
MRS. W. WELLS, rosy mauve on pale blue ground, white eye; very long spikes of loosely formed flowers; a very attractive variety, vigorous habit, 2/6.
Nettie, gorgeous pale lavender mauve, a most excellent spike, fine for cutting, 5ft., 2/6.

One of each of the above will be sent Carriage Paid for **27/6**

PHLOX

Antonin Mercie, delicate lavender, enormous flowers, 6d.
Baron von Dedem, orange scarlet, large pips, 1/-.
Crepuscle, silvery mauve with bright carmine red eye, 1/-.
Eclaireur, carmine violet with pink eye, 6d.
Eugene Danzanvilliers, pale heliotrope, a general favourite, 6d.
Europe, snow white with carmine red band, large compact truss, 1/-.
Evangeline, rich salmon pink, extra, 1/-.
Hanny Pfleiderer, cream, changing to salmon, carmine centre, 9d.
Meteor, soft pink with light eye, 6d.
Mrs. Oliver, salmon, white centre, 6d.
Nana Coerulea, purplish blue, 1/-.
Suffrage, salmon rose, rose centre, 6d.

One of each of the above will be sent Carriage Paid for **7/6**

SPRING

IN company with other more or less distinguished authors, I feel that it is a duty to usher in Spring with a sweeping bow and an apt quotation. I have ransacked memory for something suitable, but my imagination boggles at the usual seasonable sentiment. The blood is not coursing through my veins as it would at the approach of warm weather; on the contrary, the central heating is functioning properly in the room and there is a pleasant fire in the grate. The most appropriate quotation I can recall is a sentence at the start of one of O. Henry's stories: "It was a day in March." It is short, but it is full of meaning. It says plainly that the time has not yet come to lay aside winter underclothing, for the climatic somersaults are about to commence; it means that those curious creatures who rule the weather are just getting into practice; it states that Spring is a wanton jade who requires careful watching.

As a people we have no illusions about our climate, and perhaps it is just as well. There are few countries in the Temperate Zone where gardening is possible throughout the winter, or where such a variety of plants can be grown We can even excuse the gymnastics of the weather. Think how dull it would be to know that frost would cease next Friday for the season, and would start again on October 1st. Horticulture would be accomplished with mathematical precision and plants would be grown by rote. The correspondence columns in the papers would be empty, for there would be no reason to write lengthy letters announcing the first snowdrop or cuckoo. Horticulture by the clock is possible in better regulated climates; but how dull.

This is preliminary to wishing our readers a very successful gardening season. Last year was so poor that by the law of averages this year of 1924 should be good; but there is no knowing.

It would be interesting to compare the first twenty-five years of the eighteenth century and see how they compared with our present-day seasons. Evelyn and other Restoration writers made frequent mention of particularly severe weather, but this seems to apply actually to winter. We know that many plants no longer in cultivation in the open were frequently grown in their gardens. Among others vines were common and oleanders were often met with. This presupposes that spring frosts were, at any rate, less common than they are nowadays.

A great deal of the heavy work should be well forward, digging and trenching nearly completed, and the same with alterations, transplantings and renewals. The time is rapidly approaching when the pottering season begins, that pleasant time when a little work is done here and a little there, but the longest hours are spent in wandering around and watching plants grow and buds burst and flowers come to maturity.

Remember that THE GARDEN is at your door to give advice, not only at this season but at all times. We are not omnipotent, for we still have to learn how to manufacture a vermilion snowdrop or a blue carnation; but we are willing to assist to the best of our power.

I was about to close with this promise of assistance, but I have remembered a suitable spring quotation:

> Mean time, whilst every verdant thing
> Itself does at thy Beauty charm,
> Reform the errours of the Spring;
> Make that the Tulips may have share
> Of Sweetness, seeing they are fair;
> And roses of their thorns disarm;
> But most procure
> That violets may a longer time endure.

Even Marvell had his gardening troubles in the seventeenth century—and he also was suspicious of Spring.

Note.—In ordinary seasons planting of shrubs, fruit trees, etc., is usually finished for the season at the beginning of March. Owing to the extraordinary cold weather during January and February, planting may be continued for another two or three weeks. It is only when the ground becomes warm that planting should cease, and that is a state of affairs which, unluckily, has not been granted to us this season.

AMONG OTHER ARTICLES IN OUR NEXT ISSUE WILL BE:

HOW I CAME TO GROW GLADIOLI

BY MAJOR CHURCHER.

I THINK it must be quite thirty years ago when I first purchased a collection of gladioli. My recollection is that I received two large reproductions, in colour, of gladioli and irises from John Lewis Childs of New York, which resulted in my sending for a collection of thirty (?) varieties. Some of the names I remember were Eva, Dr. Parkhurst, Columbia, Mrs. Beecher, Boston, Lydia, Kate, Wm. Falconer, Wild Rose, Superb and Capt. C. B. Tanner. Columbia, Eva, Dr. Parkhurst and Mrs. Beecher were among those which survived the longest, the last named was the sole survivor a few years ago. Strange to say, a few days ago I received the current catalogue of Messrs. L. J. Childs and Co., and I see that they only list "the seventeen best, choicest and finest" of the Childsi group, and the only one of the old varieties named above included in the list is "Superb."

These remained my principal stock for some years with a few additions bought from Veitch, Lilley and Kelway. The most expensive one was Duke of Richmond (15s.), a strong grower, but not a great favourite of mine. Peace, Envoy, Alice Wood, Lady F. Cecil, Seamouse, Mrs. J. M. Skittery, were some of those that followed. Duke of Richmond, Seamouse and Lady F. Cecil were good doers and I think I still have a few bulbs of the last two. Mrs. J. M. Skittery, a pale yellow, edged rose, with orange centre, was a favourite of mine, but it gradually died out. Duke of Richmond I gave away. America came a year or two earlier and proved a prolific increaser, although not a great favourite of mine. It must have been somewhere about this time that I bought some Dutch varieties and a few years later I had a letter from a Dutch firm whose representative at the time was at Bournemouth. In it the firm offered one or two novelties, but no prices were mentioned, and among them was Early Sunrise. I sent an order for, among other things, twelve of this variety and by return received a reply that "before booking the order we think it as well to point out that the price of 'Early Sunrise' is £5 per bulb." This resulted in my order being reduced to two bulbs. I was also to give an undertaking not to part with the bulbs for two years at a less price than I gave for them. It was claimed that Early Sunrise was some ten days earlier than any other variety, but this I never found to be so—two or three days earlier was as near as I could judge. With me it proved a bad investment, for it was a poor increaser and although a fine flower when it first opened it always developed white spots. Notwithstanding the fact that I have not parted with any of the bulbs, my stock can still be counted on my fingers.

Dawn, La Luna, Peace, Sulphur King, Panama, Empress of India, War, Baron J. Hulot, Blue Jay and Primulinus, or as it was then called, Maid of the Mist, were among my next purchases. In the meantime I had tried my hand at intercrossing and in 1913 I had quite a number of seedlings and having joined the National Gladiolus Society I put up No. 123 in Class XIII, and was awarded a "first" for it. This was afterwards named Woodcote. I also exhibited three varieties, of which Alice Wood was one in Class XIV, and, I suppose by the displacing of the card, I was amused to read in one of the gardening papers that it caused some surprise that Alice Wood should have received the award as the best primulinus seedling!

HOW TO GROW PRIMULINUS HYBRIDS TO ADVANTAGE.

Once you have started with the gladiolus you cannot resist buying a few new varieties every year. Where you trust to catalogue descriptions you must be prepared for some disappointments, but, on the other hand, you also get some surprises, which make you forget the disappointments. You also cannot resist raising a few seedlings, ninety per cent. of which you know you will have to discard. However, you get something now and again, which, although it may fall short as an exhibition flower, is prized as of decorative value. Phyllis Mary is one of the latter. This being one of my earliest seedlings I have grown it on from year to year under a number and owing to want of space spoke of discarding it last year, but was met with such an amount of opposition that this year I decided to name it. I was told it was a favourite as a cut flower. Whether it will be a favourite outside the home circle remains to be proved.

It may be interesting to those who wish to try their hand at raising new varieties to state briefly the way to go about it.

The fertile organs, the three stamens which bear pollen, and the pistil which bears a three-cleft stigma on a very long slender stalk, are clearly visible and easily accessible when the flower opens. It is as well to have a loose muslin

Digitized by Google

bag to slip over the spike to be tied at the bottom to prevent any outside interference with your operations. Having selected a spike for intercrossing remove the first flower to open (often the first flower does not show the true character of the remaining flowers on the spike), and as the other flowers open remove, with scissors, the stamens; then when the three lobes of the stigma are seen to be spread out, lightly rub the upper surface with a ripe stamen from a flower of the other variety you have selected for the cross. This can be repeated with one or more flowers on the same spike, but I prefer not to use more than three flowers on any one spike. Afterwards cut the remainder of the spike off above the last flower fertilised. Keep the muslin bag on for a week or ten days and in about three weeks the swelling of the pods will give evidence of the success of your operation.

As soon as the pods begin to open, care should be taken not to allow them to remain too long on the spikes. They should be gathered and placed in a saucer in a dry, cool place until the seeds can be shaken out. The seeds may be sown in boxes and raised in the house, or they may be sown in the open ground at the end of April or early in May. I usually sow the first week in May in the open ground, and at any time if grown in the house. Germination is irregular in most cases, but the seedlings begin to appear in from five or six weeks. The seed bed should not be allowed to become dry.

How soon you may expect to see the result of your efforts depends on your own watchfulness. Care should be taken to keep the seedlings growing. Messrs. Lowe and Gibson exhibited a spike—the result of a Byron L. Smith × Nora at a meeting of the Royal Horticultural Society in October last. It was a fine bloom and rather of an unusual shade of colour. The seed was only sown in February of the same year. It will be interesting to watch the progress of this flower. If it lives up to its promise I think it will prove a popular variety. Messrs. Lowe and Gibson will, no doubt, surprise us this year with a number of seedlings which they have tried out. Messrs. R. H. Bath, Limited, had one particularly good red variety at one of the R.H.S. meetings, which I hope we shall see again this year under a name. Messrs. Kelway and Son always show a large number of new varieties each year, but this is only to be expected of a firm which has, I suppose, produced more varieties than all the English growers put together. Unfortunately, I did not see their new one named Palestine at the Holland Park Show. Mr. Edwards of Cambridge was also an exhibitor of seedlings during the past year and no doubt he has others which will come up for inspection during the present year. His Topsy was one I marked to try.

There are doubtless many others who have some seedlings which they are bringing along in the hope that they may meet with a favourable reception from the public when the stock is sufficient to justify their presence on the show bench. One amateur in the North wrote to me some time ago that he had one or two seedlings of merit and I hope that this year he will send some up to the R.H.S. meetings.

Up to the present, apart from Kelways, most of the new varieties have come from Holland, Germany, America and Canada. The flower is also popular in Australia and I think Messrs. Lowe and Gibson exhibited a blue variety which they informed me came from there. I also had two Australian varieties in one of my exhibits—The Blush, vivid pink, raised by Mr. F. Beacham, and Marie Lyon, also a pink, raiser unknown. I hope to try a few more Australian varieties this year.

The English catalogues have contained very short lists of late years, but I notice that Messrs. Barr's list has commenced to grow again. The only French catalogue I see is that of Lemoine and Son, which shows a falling off in the number of the older varieties, but they have a short list of some new introductions, of one of which, Mme. George Boulay, a Canadian writes as follows:—

"This year (1923) Lemoine introduced a super-variety, Mme. Boulay, with pure white petals and a rather small blotch of the most beautiful light cardinal imaginable. The combination was exactly to my taste, and therefore not just what some others will prefer. This variety is sold at a price altogether too high [The price was, and is, 10s. each] but I got one in a moment of weakness, and now want more. Prophecy is a poor game to follow, but if Mme. Boulay does not win her way, I shall be surprised."

To those who would like to try growing gladioli I would suggest a selection from the following varieties:—

LARGE-FLOWERED SECTION.

*Byron L. Smith, a light lavender, faintly lighter toward the inside, cream on the lower petals.

Challenger, a strong-growing plant, 4ft. high, flowers 5ins. across, rich dark orange red, a good self colour.

*E. J. Shaylor, deep rose, lighter towards the centre.

Loveliness, a beautiful cream coloured variety of good form and substance.

Incontestable, pure white, lower petals a carmine and orange blotch. Distinct and beautiful.

Jenny Lind, a pure soft apricot pink, throat pale yellow. An exceedingly refined and attractive variety.

Lustre, dark orange vermilion.

Mrs. Frank Pendleton, bright rose pink on a pure white ground with a large blotch of richest carmine red on lower petals.

Mrs. H. E. Bothin, something like the last named, but a more refined flower.

Nora, light violet blue, lower petals and throat with small spots of a trifle darker hue.

Golden Measure, a large, fine yellow, well formed flower spike, tall and strong plant. This and "Gold" are no doubt the finest yellows at present.

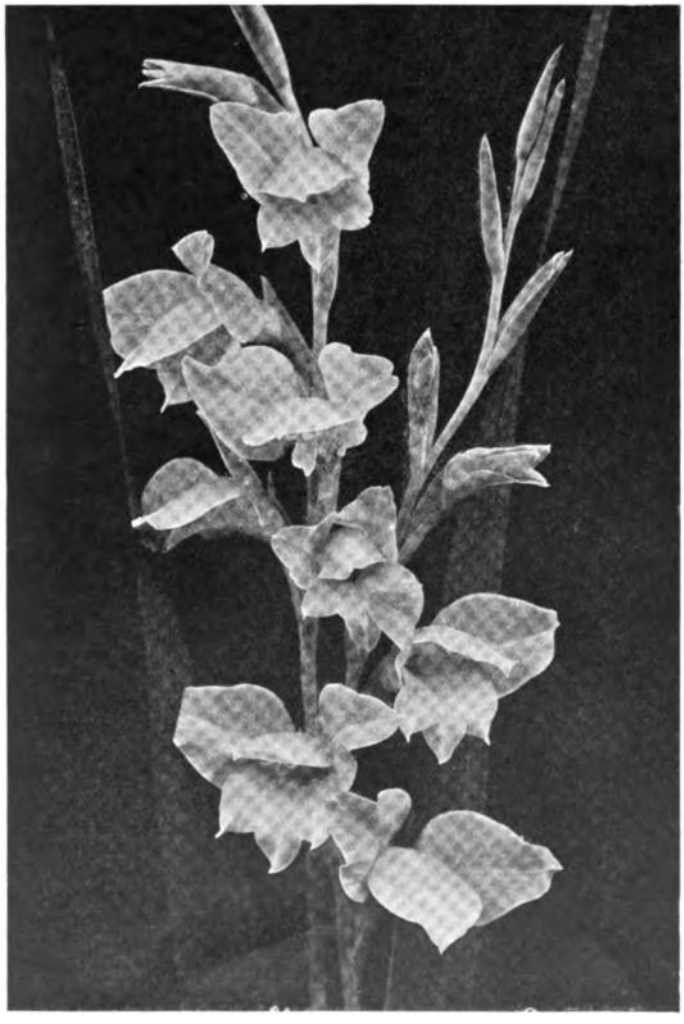
Red Canna, a tall rich dark scarlet red.

*Red Fire, entire flower of richest pure self-coloured bright red.

Rev. Ewbank, a light lavender or porcelain blue, early.

Baron Joseph Hulot, dark violet, bordering blue.

Purple Glory is a very deep velvety reddish maroon, blotched nearly black; extra strong grower, excellent substance, beautiful and distinct.



NYDIA, A PRIMULINUS HYBRID.
A bright apple-blossom pink shaded with rose.

Digitized by Google

White Giant.—A Dutch variety which differs entirely from Kunderd Giant, white.

*Mary Pickford, an early variety, the creamy or sulphur shade is more pleasing than the dead white of White Giant.

*Snow Glory, one of the grandest gladioli. It is white, very faintly sulphured on the lower petals, with a fine iris blue line. This was one of the high-priced ones and is only slightly cheaper than it was.

*Perfect Peace, white with a pale pink stripe on the lower petals.

INTERMEDIATE SECTION OR MYRA TYPE.

Alice Tiplady.—This is perhaps the most popular flower in this section and might be taken as the type, but it is not so tall as Myra. The colour of Alice is rich orange saffron, quite solid, faint lines on the lower petals. Slightly ruffled.

*Butterboy, an extra tall, strong plant with large buttercup yellow flowers, nicely spaced on spike.

Linton, tall salmon rose petals bordered with a deeper shade, lower petals golden, veined rose. Heavily ruffled.

Myra, a giant flower, deep salmon over yellow ground; yellow throat with pink lines; tall slender stem.

Midsummer Dream, a geranium red self.

Primunella, a very beautiful ruffled butterfly orchid-like flower.

Jewel, a new primulinus, clear salmon pink, with golden yellow throat.

Liberty, deep salmon pink, yellow blotch.

Sunrise, light yellow, shaded orange.

PRIMULINUS—NYDIA TYPE.

Altair, extra tall, of finest salmon saffron.

Bobolink, tall, slender spike, orange tinted yellow, with entire lower petals of richest deep daffodil yellow, deeper in throat.

Faun, bronzy pink on yellow ground.

Elberton, tall, finest creamy yellow.

Golden Girl, a rich golden yellow.

*Hermione, salmon orange, red blotch on yellow ground.

Nydia, a bright apple blossom pink shaded rose pink.

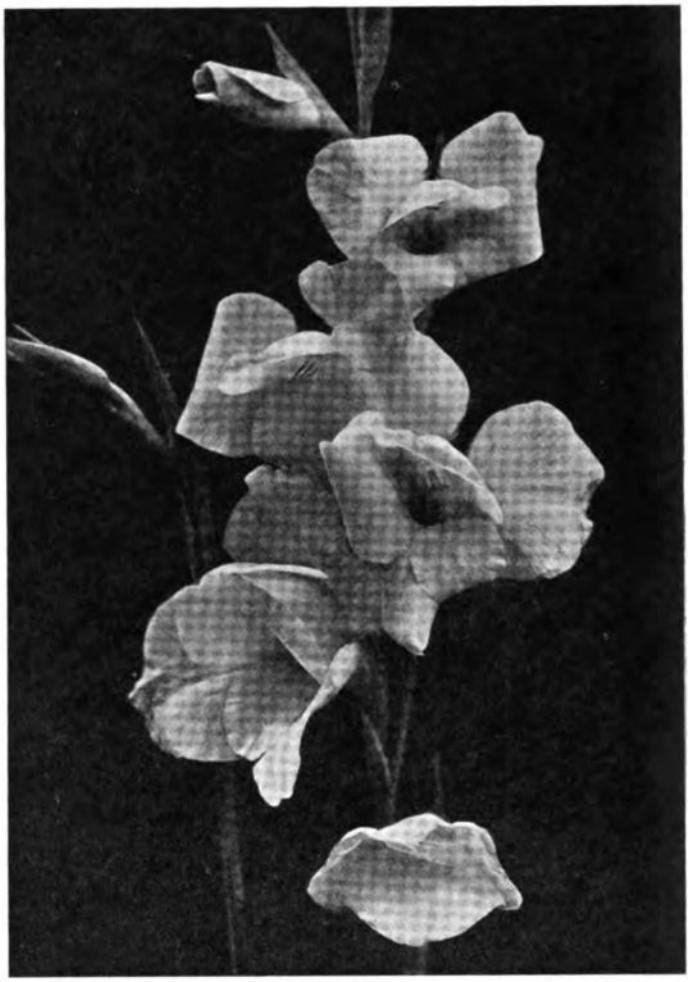
Orange Brilliant, apricot orange.

*Souvenir, yellow, perhaps the most popular of this colour.

Scarletta, outside dazzling scarlet, inside fiery cinnabar.

Those varieties marked with an asterisk have received the A.M. of the Royal Horticultural Society.

To those starting, I would only add, do not buy too many of one kind. Tastes differ, and the purchase of more varieties the first season will enable you to select, not only what you like best, but also those that suit your own soil.



A BEAUTIFUL GLADIOLUS, LIBERTY.
Deep salmon pink with yellow blotches.

NEW AND RARE CONIFERS

BY E. H. WILSON,
OF THE ARNOLD ARBORETUM.

JUNIPERUS SQUAMATA VAR. FARGESII.

THIS handsome juniper is an arborescent form with recurving and hanging branchlets, native of the mountains of western Hupeh and Szechuan. Usually it is a small tree from 15ft. to 40ft. tall, but that it grows to a much larger size the accompanying photograph attests. The tree depicted was 85ft. tall, with a trunk 22ft. in girth, and by far the finest specimen of its kind met with on my travels in western China. In large trees the trunk usually divides at about 10ft. above the ground into several erect stems; the lateral branches are ascending-spreading with recurving apices, and the slender branchlets are quite pendent. It was discovered round Chengkou-ting in north-eastern Szechuan some time between 1892 and 1900 by Père Farges. In 1908 I collected seeds from the large tree of which the picture is given, and these have reproduced the fine qualities of the parent.

Like many other junipers, J. squamata is a polymorphic species. The form to which the name was given is a low-growing plant which closely hugs the ground, and was introduced into England from Sikkim about 1836. In gardens it has been confused with the Japanese J. procumbens, and sometimes masquerades as J. pseudo-Sabina, both quite different plants; but neither under its own or any other name is it as common in gardens as it deserves to be.

Besides this type and the var. Fargesii, there is another tree form which has been named var. Wilsonii. This is a fine tree fairly common in sheltered gullies in western China and is particularly abundant on the higher, forested slopes of Mount Morrison in Formosa. At its best this is from 60ft. to 75ft. tall, with a fine straight trunk and horizontally disposed branches. This variety was introduced in 1893 from north-western China by Messrs. Vilmorin Andrieux et Cie., and plants raised from seeds received from this firm are growing in the Arnold Arboretum. In 1909 I sent seeds to the Arnold Arboretum from western Szechuan, and many plants from this source have been distributed.

Yet another form is var. Meyeri, which is an upright shrub from 5ft. to 6ft. tall, with dense, short branchlets and bluish grey foliage. This ornamental plant was introduced into America from Chinese gardens in 1914 by the late F. N. Meyer, who sent it to the United States Department of Agriculture.

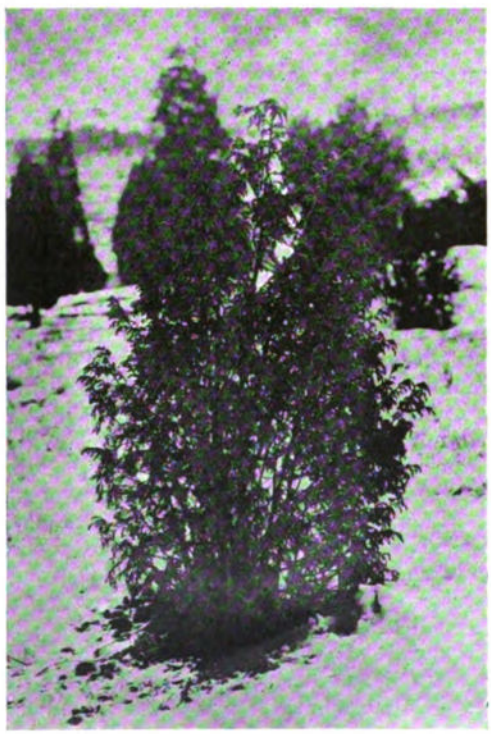
JUNIPERUS CONFERTA FROM THE JAPANESE SEASHORE.

In its various forms Juniperus squamata is the common mountain juniper of central and western China, and extends its western limits to the Sikkim Himalaya and its eastern to the high mountains of Formosa. Throughout the alpine regions of the Chino-Tibetan borderland it covers immense areas between elevations of 12,000ft. and 16,000ft., an altitude higher than any other woody plant except the diminutive Ephedra Gerardiana var. sikkimensis. I have also collected it on the crumbling summit of Mount Morrison (13,075ft. above sea level) in Formosa. On mountain-tops and wind-swept slopes it is prostrate or nearly so, and covers vast areas. Where the contour of the country offers some protection from wind it is a shrub of tangled growth from 4ft. to 6ft. high, with spreading interlacing branches, and forms a perfectly impenetrable thicket. In sheltered gullies and in the forests of silver fir it is a tree often of large size. The branches are used for incense in the lamaseries and houses of the Tibetan and related tribes.

Such is the story and geographical range of J. squamata, the ecological forms of which come fairly true from seed and deserve to be better known in English gardens.



A SEEDLING OF JUNIPERUS SQUAMATA VAR. FARGESII

JUNIPERUS CONFERTA.

This is a littoral species with a remarkably wide distribution along the seashores of the Japanese Empire, having its southern limits in the Liukiu Islands and its northern in Saghalien. The habit is always prostrate, and it usually forms dense broad mats; but where it is not crowded, as on recently formed sand dunes, the trailing branches are flagelliform. The leaves are very numerous, narrow, linear, with a fine white band above, pale green with a prominent keel on the underside, and taper to a spiny point. The fruit is globose, bloomy black when ripe, three-seeded, produced in great abundance, and is very variable in size.

This juniper was discovered in 1854 by the American botanist, Charles Wright. It was introduced into cultivation by seeds collected by me in 1914 and sent to the Arnold Arboretum. Though quite a common plant in Japan, it seems to have been overlooked by previous collectors, and was, indeed, unknown to Japanese nurserymen and gardeners until I brought it to their attention in 1914. It is essentially a seashore plant and is quite unaffected by the salt spray and high tides. When it comes into more general cultivation, it might form an association with Pinus maritima for reclamation work on sandy coasts.

The whole plant is a cheery bright green throughout the winter and should be of great value for covering sand dunes and as a ground cover in shore gardens. It has proved hardy in the Arnold Arboretum, though it continues to grow late into the autumn, and the tips of the branches are often killed back by winter frosts. On Long Island, New York, it is perfectly happy. In the south and west of England this juniper should flourish.

(To be continued)

J. SQUAMATA VAR. FARGESII, 85 FT. TALL IN CHINA.

THE ART OF BUDDING

BY L. B. STEWART
(ROYAL BOTANIC GARDEN, EDINBURGH.)

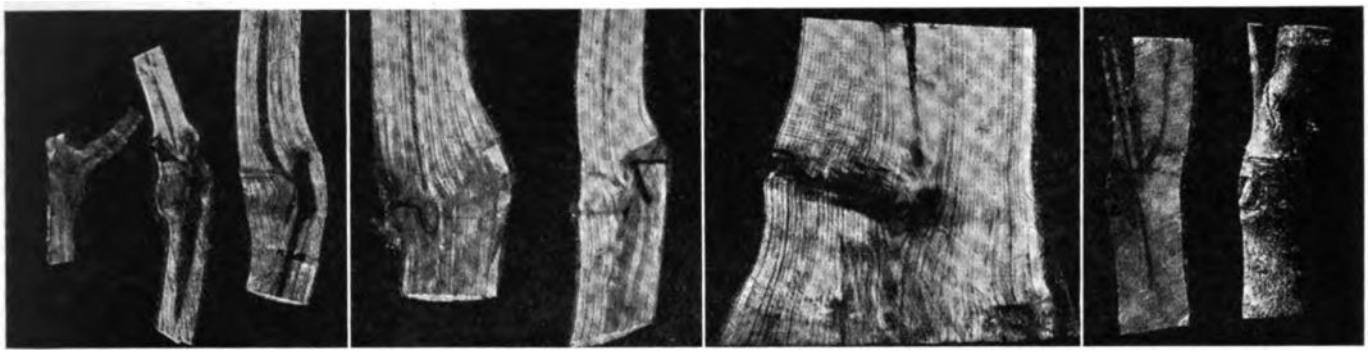
BUDDING of fruit trees, roses, acers and other plants is a very well known way to produce on a large scale. A great many of the hybrids, or varieties, or sports, of a species cannot or will not lend themselves to propagation by vegetative methods, *e.g.*, cuttings or layering, or cannot be raised true from seed. The process of budding is a very simple one, and can be done by anyone after a little practice and ordinary care, and with the following facts kept constantly in view: The stocks must always be in an active state of growth, so that when the operator cuts the bark of the stock, it can be lifted easily from the wood, in which case no tearing takes place. Should the bark be in the least hide-bound there will be no success. The scions must be absolutely fresh, and when the buds are taken off the leaves should be removed, only leaving enough leaf stalk attached to make the buds easily handled. The eye of the bud must be intact. If the eye of the bud is fractured or is removed, then no success will be attained. In removing buds from the scion it is best to start removing the buds from the apex of shoot first. It will be found that the first, second and third buds next to the apex of the shoot are seldom used because they are not firm or mature, and often are so small that they are difficult to handle.

The insertion of the blade takes place about half an inch below the bud. After the knife blade has passed the bud, the thumb of the hand presses against the then stationary blade and the bud is torn off towards the apex, after which the bud lying in close connection with the wood is removed. The following action must be done quickly: Raise the bark and with the one hand hold the bark portion firmly, with the other hand remove wood portion with a sharp jerk. The tail end of the portion torn off is only used for handling, and when inserted in the stock is cut off at the top of the "T," so that it fits exactly into the cut of the stock.

The preparation of the stock is an important process. With some stocks, such as roses, the soil round the neck of the stock is removed, so that the bud is placed in a position as near to the root of the stock as possible. It will also be found that the bark is at that part thinner and much easier to work with than bark on the level or above the level of the soil, and there is less room for suckering.

When budding, one comes across plants which have varied thickness of bark. It is very difficult to tell exactly how deep the knife should be inserted when making the cut, but when the operator inserts the knife blade it makes a click, which is not heard but felt by the operator, thus letting him know that he has reached the bottom or cambium layer of the bark. Bad budding (Fig. 1, left) is often the result of carelessness, and what really takes place is that the knife blade is inserted too deeply and goes beyond the cambium layer into the wood. At that particular part of the stem, with the cutting of the stem, air gets into the wound and the cells which have been cut become oxidised, so that healing never takes place in the centre of the bud portion of the stem, but goes on round the outside of the bud portion of the bark. The result of this is very evident when, on going through a brake, you may see plants which have misthriven and will never make good plants for the purpose for which they were intended. The operator then completes the "T." After he has made the horizontal cut in the bark he inserts the point of the blade at the required distance below the top cut—say 1½ins. or so, according to the size of the stem and kind of tree or bush which is being worked. The main thing to be observed is that when the blade comes to the top and has reached the horizontal cut, the bark is flicked with the point of the knife, thus enabling the bark raising portion to be inserted with greater ease. Some budders have different methods of making their "T." I think that the top of the "T" is better made at an angle of 45°, as it has the effect of draining any moisture from the far side of the stem, whereas if made horizontally there is a tendency for water to lodge at the top cut surface, at close proximity to the introduced bud.

The tying in of the buds is generally an operation which is done by a boy if budding is being done on a large scale, but when a few are being done the budder generally does it himself. The tying should start at the base and finish at the top. When the tie reaches the top of the bud it is advisable that it should be tighter than at the start, thus ensuring a good union. If there should be a slight flaw in the budding, the tight tying at the top stops the flow of sap. In finishing off tying, the knot should be at the back of stem.



From left to right: 1, CARELESS BUDDING, MISTHRIVEN APPEARANCE IS EVIDENT; 2, SHOWS MOVEMENT OF BUD; 3, TERMINAL POSITION REACHED; 4, NOTE LENGTH OF SNAG AND EFFECT OF NON-REMOVAL.

After budding has taken place, the top part of the stocks can be reduced to a short length to ensure that too much draining of the sap, or protoplasm, from the bud does not take place. (Fig. 4.) These snags are left on until the following year's growth is completed, but during the season the snags are used for tying the young bud growths in order to support them in case they should be broken off by the wind. They also act as safety valves to the buds where stocks may prove to be too vigorous, as they sometimes throw the bud out by exuberant growth. When snagging starts they are cut off as near the buds as possible, then the movement of the bud commences.

To all budders it is well known that when the bud is inserted it is placed in the side of the stem and is in a lateral position. As the years go on, however, the bud begins to move (Figs. 1 and 2), and after a few years it will be found that it has travelled round an angle of 90°, or a fourth part of a circle, thus forming a sympodial axis, and has attained the terminal position (Fig. 3). The position of the stock snag has been forced to the side and is now lateral. The growing vascular strands between the stock and bud are continuous after the first or second year's growth has taken place. On the opposite side from the bud the snag end heals up by occlusion. It will be found, however, that in many cases the healing is never perfect at this particular point, and is always a weak portion of the plant. It is, therefore, important never to have the snag end side of the plant facing the prevailing winds, as it proves an easy victim to the gale. The mark left in the healing process is very narrow, being the thickness of the snag, so that only a very small part of the stem is not healed. There are cases, however, where this healing is complete, the only indication being the cross-grained wood in the longitudinal section.

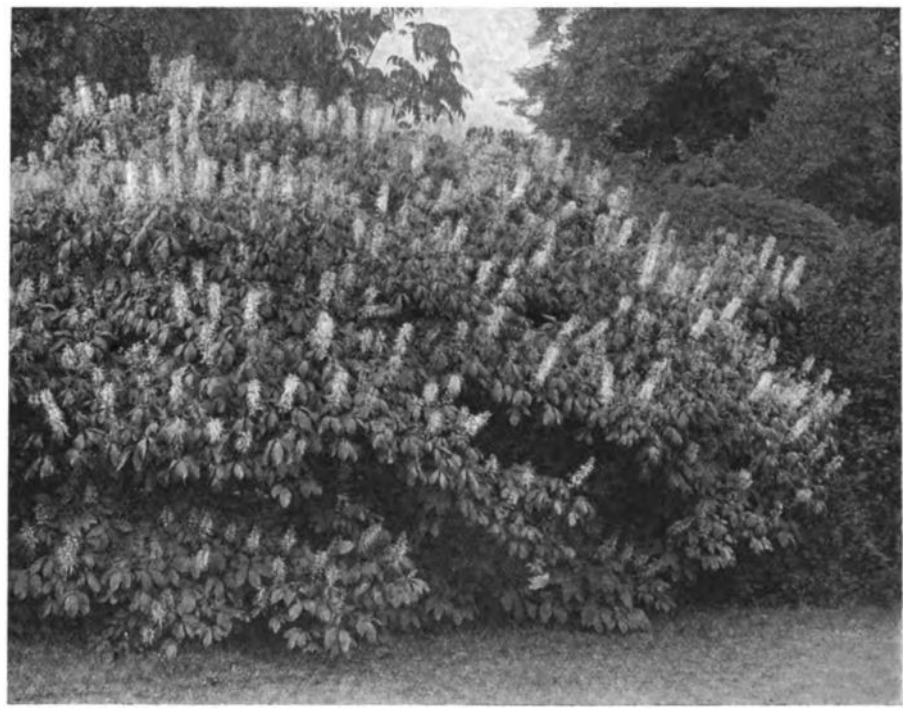
FLOWERING SHRUBS FOR A MODERATE-SIZED GARDEN.—IV

BY W. J. BEAN.

LATE-FLOWERING SHRUBS.

THE great majority of trees and shrubs, perhaps nine-tenths of them, flower between the end of March and the end of June. Still, a considerable number come into bloom from July onwards, and in any select list some of them must be included. A number of these have already been incidentally mentioned, but there are yet others that deserve separate notice. Everyone who sees it in flower is attracted by Eucryphia pinnatifolia, of which the flowers open in July and August, each 2ins. to 3ins. wide, white with a conspicuous cluster of yellow stamens in the middle. Like many Chilean shrubs, it likes moist, cool conditions at the root, and in the hot, dry Thames Valley, at any rate, is happier associated with other shrubs that shade the ground without unduly robbing it. Privets in a garden are anathema to many people, and quite rightly so; yet three of them may escape maledictions, viz., Ligustrum chinense, flowering in July; L. lucidum, an evergreen flowering in September; and L. Quihoui, still later. The last is not well known, but Mr. Vicary Gibbs has appreciated its merits at Aldenham and showed it well last autumn at Vincent Square.



A SHRUBBY ALLY OF THE HORSE CHESTNUT, ÆSCULUS PARVIFLORA.

The shrubby veronicas are too uncertain in regard to hardiness to be relied on to any great extent; but V. Traversii flowers in July and is always a pleasant-looking shrub until it gets too old; still, it is increased so easily by cuttings that its renewal is a small matter. A garden variety called Autumn Glory, with bright blue flowers, seems very hardy and gives a bright effect for many weeks in late summer and autumn.

Among shrubs flowering in July a high place must be given to Plagianthus Lyallii for the profusion of beautiful pure white flowers it bears. It comes from New Zealand and in very hard winters may be killed back to ground level near London, but I have never known it to be destroyed entirely. Two forms are in cultivation, one with smooth leaves and of purely shrubby habit; the other with downy leaves, a sturdier more tree-like habit, more cup-shaped flowers and thicker petals. While both are good, the latter is preferable.

Tamarix pentandra, which came into cultivation some twenty years ago as "hispida æstivalis," a wrong name that still sticks to it in many places, is a very pleasing tamarisk, flowering in August and September, its branches then transformed into long slender plumes of rosy pink blossom. It can be propagated by cuttings of winter wood as easily as a willow, and may be pruned hard back every spring if it is desired to keep it under 5ft. in height. Of about the same hardiness as the Plagianthus and similarly affected by very hard frost is Abelia grandiflora, a hybrid which goes under several wrong names, including "chinensis" and "rupestris." It is inferior in beauty to A. floribunda, a tender Mexican species needing the protection of a wall, but is the best of the kinds hardy near London. Its flowering time extends from July to October, during the whole of which period it bears a succession of its pink-white, funnel-shaped flowers.

ONE OF THE MOST ATTRACTIVE HYDRANGEAS PETIOLARIS.

The shrubby ally of the horse-chestnuts, Æsculus parviflora, a neat bush with handsome leaves and terminal erect racemes of pink and white blossom, opening in July, has been too much neglected. The escallonias mostly bloom after midsummer, and the hybrids known as langleyensis and edinensis are pleasant, graceful evergreens bearing clusters of rich red flowers. Of hypericums I consider the best, on the whole, is H. patulum var. Henryi, a comparatively recent acquisition from China, very hardy and easily cultivated, and bearing fine clusters of bright but rich yellow flowers from July onwards. Buddleia variabilis is a

Digitized by Google

somewhat gaunt plant, but at least one of its varieties introduced by Wilson—either Veitchiana or magnifica—must be grown for the splendid panicles of lilac or violet-purple blossom, fragrant and beloved of butterflies.

There are many varieties of Hibiscus syriacus in cultivation, from which may be selected totus albus (pure white) and cœleste (blue); they need a well drained soil and full exposure to sunlight. A hot dry September is needed to bring out their best qualities.

The most attractive of hydrangeas to my mind is petiolaris grown as a shrub, although naturally it is a climber; it also flowers in June. Of the rest, H. paniculata grandiflora and H. arborescens grandiflora, flowering two or three months later, are most to be recommended. All these have white flowers.

YUCCAS.—So different are the yuccas in general aspect from any other hardy shrubs, and so distinct a note do they strike, that the genus cannot go unrepresented in our select garden of shrubs. Undoubtedly the most reliable of them all is Y. recurvifolia, a very hardy plant succeeding in any sunny position and pretty indifferent as to soil. When crowned in late summer with its immense panicle, 2ft. to 3ft. high, of creamy white flowers, it always excites interest and admiration. Y. gloriosa has an even longer panicle (occasionally 4½ft. high) and is quite as hardy; but sometimes, especially after flowering and in snowy winters, damp settling in the crown is apt to set up decay. Yucca flaccida and filamentosa do not develop stems above ground level, and the plants keep about 2ft. high; they also develop fine panicles of yellowish white blossom. Both like a well drained position.

FRUIT-GROWING IN SMALL GARDENS.—III

BY RONALD G. HATTON, M.A.,
OF THE EAST MALLING RESEARCH STATION.

SUITABLE VARIETIES FOR THE SMALL GARDEN.

WITH regard to selection of varieties of top fruits for the small garden, as far as possible, your aim should be to choose for a complete succession varieties of moderate vigour, good quality, varied flavour and sure cropping capacity.

APPLES.

In the case of apples my choice would probably be the following list, and with possibly two or three exceptions, I should grow my selections as single cordons or trained trees on Jaune de Metz Paradise (Malling Type IX). I should probably grow Stirling Castle as a bush or pyramid on a more vigorous root such as Broadleaved English Paradise (Malling Type I). Allington Pippin would also be more manageable in bush form with a 2ft. stem, or it might be grown as an espalier.

APPLES FOR THE SMALL GARDEN.

Culinary.—Not too many.

Early Victoria or	Earliest apple tart	July.
Lord Grosvenor	Good in North	August.
Stirling Castle or		September-October
Rev. W. Wilkes	Splendid baking	
Lane's P. Albert		November-March.
Edward VII or		January-April.
Monarch		

Dual Purpose,

Allington Pippin, useful, but prune lightly.	October-December.

Late-Flowering, for frosty gardens.

Royal Jubilee	Culinary	October-December.
Court Pendu Plat	Dessert	December-March.

Dessert, a succession of fine quality and varied flavour.

Langley Pippin	approx.	August.
St. Everard or	,,	September.
Lady Sudeley	,,	,,
James Grieve	,,	October.
Ellison's Orange	,,	,,
Egremont Russet	,,	November.
Cox's Orange Pippin	,,	November-December.
Christmas Pearmain	,,	December-January.
Blenheim Orange	,,	December-February.
Orleans Reinette	,,	,, ,,
Upton Pyne	,,	January-March.
Belle de Boskoop	,,	January-April.
Heusgen's Golden Reinette	,,	March.
Duke of Devonshire	,,	April.
May Queen	,,	May.
Easter Orange	,,	June.

A list such as this may require some adjustment according to local conditions of climate and soil, but the possibilities of adaptation in a sheltered garden with made soil are far greater than under open conditions.

If two or three cordons each of my list were planted one might look to average, on a very conservative estimate, 3lb. or 4lb. of good fruit per unit. On our Cox's Orange Pippin cordons on Jaune de Metz stock (Type IX) in their second year we averaged over a dozen good fruits per cordon or over 2½lb. Each apple was as fine as the specimens we see in the shops, at 6d. each, yet you could have bought the maiden tree outright for 2s. Not a bad investment! I have seen the intractable Blenheim Orange, on the same stock, bearing several nice fruits in its second season, and we ourselves have had other slow cropping varieties, such as Bramley Seedling, cropping heavily at two years.

PEARS.

I think I should confine my pear growing to a very few summer and autumn fruits of known cropping capacity, and I should most certainly grow these in dwarf form upon Angers quince (Malling Type A), wherever possible.

My selection might be as follows:—

Doyenne d'Ete	Dessert	July.
Laxton's Superb	,,	August.
Souvenir de Congrés	,,	September.
Dr. Jules Guyot	Appearance	September.
Conference	Dessert	October-November.
Dorondeau	,,	,, ,,
Emile d'Heyst	,,	,, ,,
Beurré Hardy	,,	October.
Roosevelt	Large	,,
Charles Ernest	,,	November.
Fondant de Thirriot	,,	November-December.

CHERRIES.

My stone fruits would be still more limited. If I had a piece of north wall or an ugly shed to hide I should plant a Morello in trained form, which could be protected from birds, and, if I wished to break the monotony of trained trees for sake of picturesqueness, I might work into my scheme a standard Flemish red cherry, so sure of cropping, so good for bottling, less attractive to birds than the sweet cherry, sweet of aroma, and dainty and fairy-like in its growth and colouring, lending the atmosphere of a Kate Greenaway picture. Both these cherries are self-fertile.

PLUMS.

My choice of plums would also be restrained. Unless I had a good warm wall (in a latitude unsuitable for outdoor peaches), I should not attempt a wall plum, despite the lure of the uncertain gages and Coe's Golden Drop! The growing of plums as cordons is no very easy matter at the present time. Though some root stocks are found to encourage earlier fruiting and give slight restriction, as yet it is only possible as a rule to grow cordon plums by lifting them every two or three years. The small gardener has usually neither time nor inclination to go to this trouble. I should therefore confine my selection to a few medium-growing, sure-cropping self-fertile varieties of general purpose, and I should only work these in if space allowed.

Purple Egg or Czar	Culinary	August.
Utility or Early Transparent Gage	Dessert	August.
Victoria		Early September.
Burbank's Giant Prune	Culinary	Late September.

Digitized by Google

In our small gardens in the South, South-East and West, we are jealous of any south wall space for an outdoor peach. Hale's Early (July) is probably the hardiest and even succeeds far north. Goshawk (August) is also hardy and delicious. Hardwicke (August) is probably the hardiest nectarine, but the small gardener will be wise to limit his ambitions in this direction or he will be apt to find that the tying in and disbudding of his precious wall fruits will occupy a disproportionate amount of time. He will be pleasantly surprised, however, if he obtains a three year old fan-trained peach, and keeps it well supplied with moisture in the initial season, how quickly he may produce a few fine coveted fruits, and cover his wall.

In this question of selecting fruits, science has again helped us. We now know that many varieties will set little or no fruit if their blossom is not cross fertilised. We know that other varieties can stand alone and still crop. Science has helped to tell us which varieties to plant together and which to avoid. We need no longer have our solitary barren disappointing fruit trees, blossoming freely but bearing no crop.

SMALL FRUITS.

A few healthy bushes and canes of well chosen small fruits should in a large measure supply the current household needs, though the housewife will look further for her jam fruit. Half a dozen black currants, the same number of reds and gooseberries, to supply all needs, will require careful judgment and good management, however, for in many gardens the bush fruits are valueless through neglect or old age.

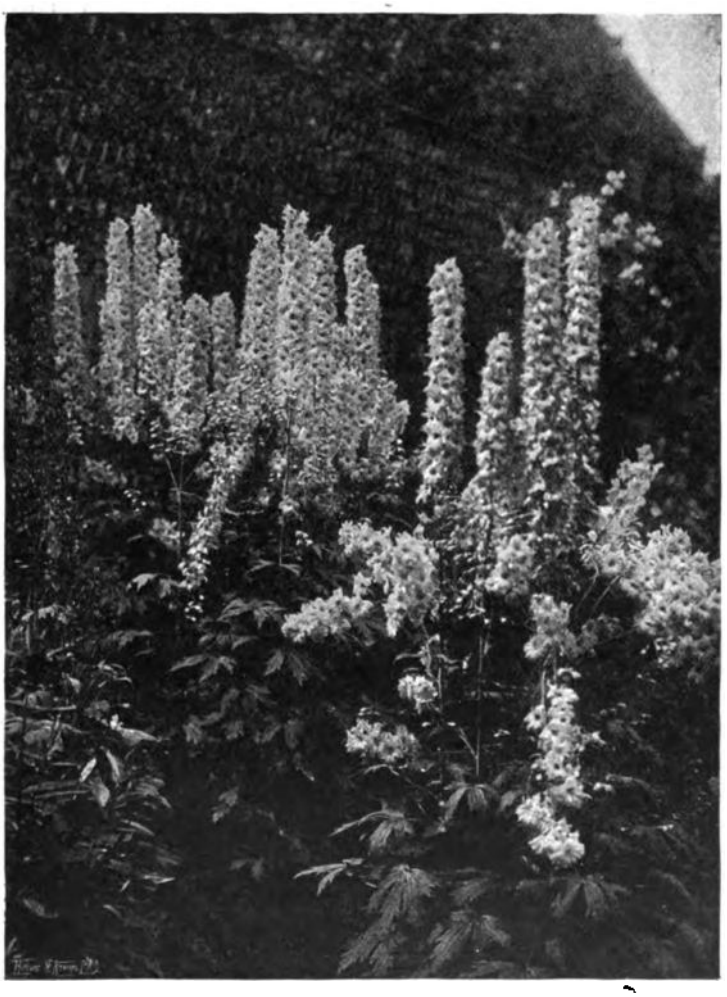
I have already hinted at my choice when I mentioned the well planned garden, so I need not say more.

CULTIVATION OF DELPHINIUMS

BY J. FRASER

FROM the earliest of gardening times delphiniums have been popular in this country. One of the parents of the fine modern strains was Delphinium elatum, a tall-growing species, native to Europe and the Himalayas. A great impetus was given to the raising of improved forms by the introduction of D. formosum from Armenia after the middle of the last century. This species brought large deep blue flowers tinted with indigo, and handsome finely divided foliage. These two were hybridised and the resulting forms crossed with one another, with the results we now see, but whose limits of improvement we do not yet know.

Delphiniums require a deep rich mellow loam to ensure their best development, but not every garden can supply this want. Every good British gardener, however, is equal to the occasion when called upon to grow them in the soil at his command. He will see that it is well drained, deeply trenched, well manured and otherwise ameliorated with the means best calculated to bring it into the required condition. Depth is necessary to prevent it from getting dried up in summer, whether the soil is light or heavy, for delphiniums require a steady and ample supply of moisture all the summer through, especially during May, June and July, while the stems and the long spikes of bloom are being produced. In addition to manure, sand and road grit will open up the heaviest of soils, while depth of culture and manure will greatly improve the light ones. Copious supplies of water may be given to both these classes of soils during periods of drought with advantage to the flowers, while it is always open to mulch the plants with manure or something else that will conserve the moisture where copious watering is out of the question. Frequent stirring of the soil with the Dutch or the flat hoe is almost as good as mulching, and certainly a better expedient than frequent driblets of water, which cake the surface soil without penetrating it, for hoeing is then more imperative than ever. No good gardener would grudge the necessary preparation of the soil, but consider himself well repaid in proportion to the results. This is no more than any other class of herbaceous plants requires, and delphiniums are not in any way exacting in this respect. Indeed, they may be planted in any well kept herbaceous border with every assurance of success.



DELPHINIUMS, ONE OF THE GREATEST JOYS OF THE SUMMER BORDER.

PROPAGATION.

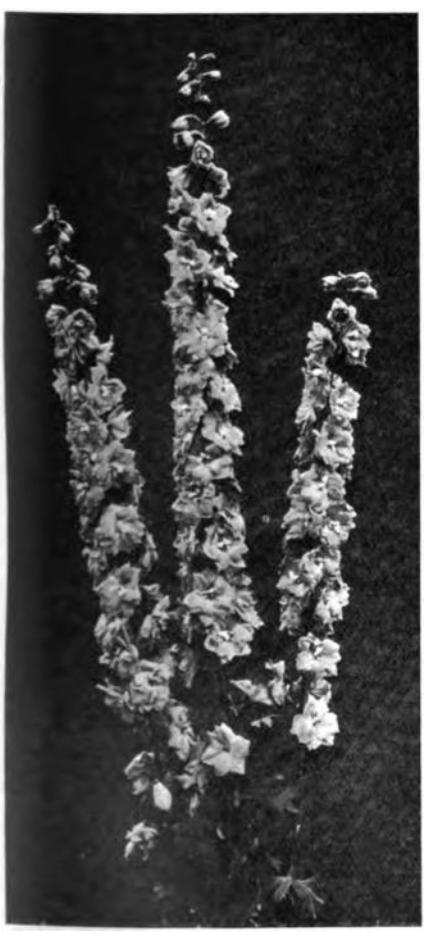
This is effected by seed sowing and by the division of named varieties to increase them true to name. In spite of the numerous magnificent varieties in cultivation, a great many people will continue to raise delphiniums from seed in the hope of getting something superior or different from those already existing. The ordinary seedlings are quite good for garden decoration when raised from superior strains of seed, but the discerning enthusiast will not rest content at that. The hope continually arises that something better will fall to his lot, so that the seed beds are eagerly and frequently inspected with the expectation of finding it when the plants are coming into bloom.

Seeds are usually ripened in abundance by the plants that are allowed to produce them, and for this reason can be procured cheaply from those who have collections of the best varieties. They can therefore be sown in any reasonable quantity. It should be remembered that delphinium seed, when sown in spring, often takes a long time to germinate; indeed, it may lie for twelve months before germination takes place. Much good seed has been thrown away as useless after having lingered for months without giving any results. This character of the seed is common to all the perennial and woody members of the crowfoot family (Ranunculaceæ). The remedy is to sow the seed as soon as ripe, or procure it early in autumn from the seedsmen or those who offer it. Shallow boxes should be drained and filled with any light soil such as that

Digitized by Google

used for seeds generally. The seeds should be sown thinly, covered lightly and the boxes placed in a cold frame for the winter. When the seedlings have made a few leaves they can be transplanted into other boxes, or planted out directly in a warm or sheltered border.

When the division of established plants is intended, they should be cut down after they go out of bloom, say, in July or early August, so that the division and replanting can be carried out in September after the plants have sprouted or commenced to grow again. In light and warm well drained garden soils the old clumps can be dug up, broken into small pieces with roots attached, and replanted in well dug and manured soil. This can be done at any time from late August to the first week of November, but preference should be given to September planting. Where the soil is heavy, cold or wet, the planting should be deferred till spring, say, from the beginning of March to the first week of April. A good plan, where it can be accomplished, is to put the divisions into small pots, in a light open soil, and plunge the pots in ashes in a cold frame for the winter, and they will be established and ready for planting out at the stipulated time in spring. Young plants are subject to attacks of slugs and snails, especially in heavy or clay soils, where they are always plentiful, as moisture keeps the slugs active all the winter and spring. In cold frames they are easier to protect against the ravages of these pests.

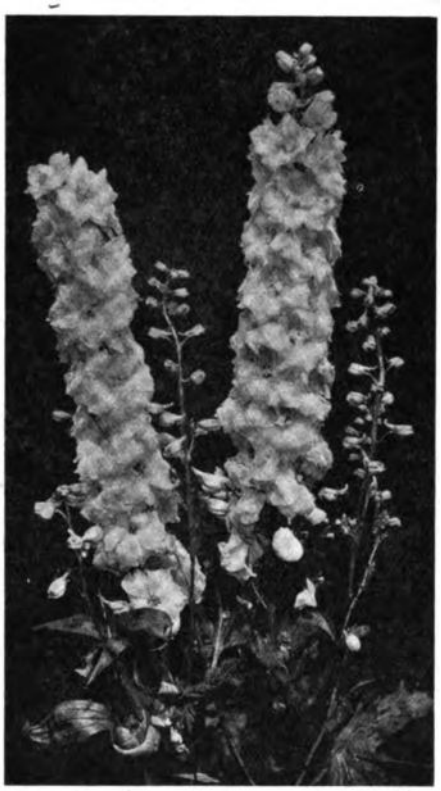


THE GENTIAN BLUE F. W. SMITH.

When planting delphiniums, a sunny or open position should be selected, for they are light-demanding subjects. The situation may be sheltered from the prevailing winds, but it should be open to the sun, because if too much shut in by trees the plants are liable to contract mildew badly. They may be planted along the back of herbaceous borders, or in other lines, according to height; or in massive beds by themselves, where they give a spectacular effect in the garden, the tallest being planted in the centre, and the dwarfer ones by gradation towards the circumference. The beds may be circular, oblong, or of any other shape with bold curves.

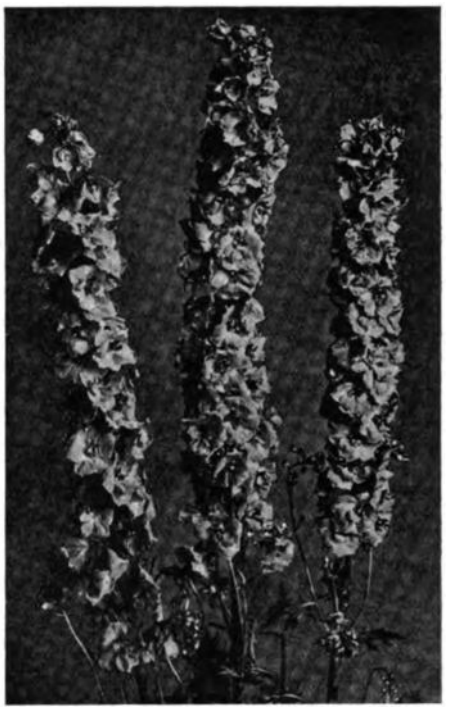
AFTER-TREATMENT.

This consists in hoeing the ground at frequent intervals, or mulching it where that is desirable or convenient, in giving



THE NYMPH, A DWARF VARIETY

copious supplies of water, if possible, during periods of drought, and in staking the stems at an early stage to prevent them from being blown down by winds or borne down by heavy rains. If broken-down stems are allowed to lie for a few days they rise up at the points and can never be straightened or made tidy again. Established plants should have their stems thinned when three or four inches high; and if very large spikes are desired, only one to three of the strongest stems should be retained and assisted with weak liquid manure. No difficulty will be found in their cultivation, if they are propagated by the above cool methods. The practice of placing stools in heat in early spring for the purpose of getting cuttings or offsets is to be deprecated. Where slugs and snails are troublesome, the crowns of the delphiniums should be



MASSIVE SPIKES OF SIR DOUGLAS HAIG.

covered in early autumn with a good coat of sharp coal cinders with the ashes sifted out.

THE BEST VARIETIES.

The beauty of a delphinium is due to the enlarged and petaloid sepals, as in aconitum, caltha and clematis. The petals are small and serve only as a guide for insects to the nectary or spur, and form the white, yellow, brown or black eye of the different varieties. The flowers become semi-double when a petal or more are enlarged, and these constitute a large number of the best modern varieties. The flowers become perfectly double when the petals and a greater or less number of the stamens become enlarged and coloured. In the sixties and seventies of last century a large number of these doubles were in cultivation, and collections of them were cultivated in beds or groups by themselves. They were characterised by small, close double flowers, and could be described as pretty without the transcendent beauty or size of the modern semi-double varieties. A few improved modern varieties are in cultivation.

It would be dogmatic to insist upon the best varieties in cultivation, because it depends very largely upon taste and individual fancy. By the consent of many General Sir Douglas Haig is considered to be the best to date. It certainly has massiveness, length of spike, and large, dark purple and blue flowers to commend it. The long spikes and very large, regularly placed soft blue and mauve flowers with large black eye of Millicent Blackmore will appeal to the fancy of many connoisseurs on account of their own intrinsic beauty. Some of the best of last year's new varieties were Blue Boy, with clear blue flowers and a small white eye; Mrs. Townley Parker, with huge, pale blue flowers, tinted with mauve shades and having

Digitized by Google

a grey eye; My Lady, with very large, pale lavender overlapping flowers; and Sylph, which has large and pure white flowers, except for the pale creamy yellow eye. Unique was a novelty in structure, for the large blue petals were reflexed, exposing the black seed vessels. Whether or not this will give rise to a new and popular race remains to be seen.

It does not follow that the newest are the best, nor that they will sustain their reputation after a few years of cultivation. Some of the best of the older ones still command the admiration of the general public, and the very fact of their holding a leading place in collections after so many years is clear testimony to their general excellence. The white-eyed beauties include many of the finest that have been with us for many years, such as Rev. E. Lascelles (rich blue), King of the Delphiniums (rich gentian blue), Queen Wilhelmina (sky blue, flushed rose), Willie O'Breen (bright sky blue), J. W. Kelway (deep blue and plum), Lord Lansdowne (intense blue, without shading), Lord Curzon (marine blue and pale aniline blue), Mrs. W. H. Day (Cambridge blue, flushed pink), Cecilia (pale blue and pink), Mrs. W. Wells (rosy mauve on pale blue) and Duke of Connaught (bright gentian blue).

A few of the black-eyed varieties of surpassing merit are Amos Perry (rosy mauve, flushed sky blue), Twertonian (cobalt blue, of branching habit), E. A. Bowles (with very large rich gentian blue flowers), Dusky Monarch (purple on very large spikes), Mrs. Creighton (Oxford blue, with plum centre) and President Wilson (sky blue suffused with mauve). The above lists might be greatly extended to include really fine things, but The Alake with its stately spikes of rich purple flowers, marbled with blue, can scarcely be omitted from the nucleus of a collection.

Those who admire perfectly double flowers should not omit the rich ultramarine blue Rene Gilbert; the pale blue and soft pink Nora Ferguson; the dark blue Zuster Lugten; the light blue Wedgwood, shaded white; the gentian blue, white-eyed F. W. Smith; and King Bladud, a sport from the Rev. E. Lascelles, without its white eye.

There remains the Belladonna section, generally of dwarf and always branching habit, which makes them practically perpetual flowering and suitable for cut flowers or garden decoration. The old type has sky blue flowers, Semi-plena differs by being semi-double, grandiflora is rich blue, Lamartine is gentian blue with white eye, and Persimmon is a lovely sky blue. The two latter are the loveliest of the group.

VEGETABLE NOTES

BY GEORGE GARNER.

PRACTICALLY all kinds of seeds roots and tubers required for the summer and maincrop supplies of vegetables should be available now, and the majority of these the cultivator should sow or plant in March.

Soils, varying from light to heavy, or retentive, are usually in the right condition to be stirred and turned, thus retaining their freedom from adhesiveness in all kinds of weather when being dealt with.

POTATOES.—Before the end of the month the bulk of the potatoes should be planted. If a few early varieties are planted to risk late frosts, the naturally late-maturing sorts should be planted first and the remainder of the early ones nearer the end of the month or very early in April. Heavy soils manured last autumn will not require more at this date; but in the case of light land, well-rotted manure should be freely mixed with the soil, not placed in bulk in the drills and the tubers dropped on it. A few hours or days extra, as the case may be, spent in breaking up the lumps as fine as possible where retentive soils are met with, will prove very beneficial to the crop. Whether planting in drills, or by spade or garden fork and line, the soil should be left as light as possible on the sets, the latter being buried about four inches deep. The approximate distances between the sets and rows respectively are as follows: early sorts a foot apart in the drill; eighteen inches from drill to drill; second early, fourteen inches, twenty inches; late varieties, sixteen inches, thirty inches. In the case of a very robust-growing variety two or even six inches further apart will prove beneficial. A few very early tubers may be obtained by planting some sets at the base of a wall or fence, thus reserving more room in the open quarters for maincrops. Of early varieties, Sharpe's Express, Midlothian Early, Epicure and Arran Rose are all first class. As second earlies I would recommend British Queen, Arran Comrade, Great Scott, King George, the latter not a very good shape, but a heavy cropper and of good quality. For the maincrop, King Edward VII, Arran Chief, White City, Kerr's Pink and Majestic should give good results.

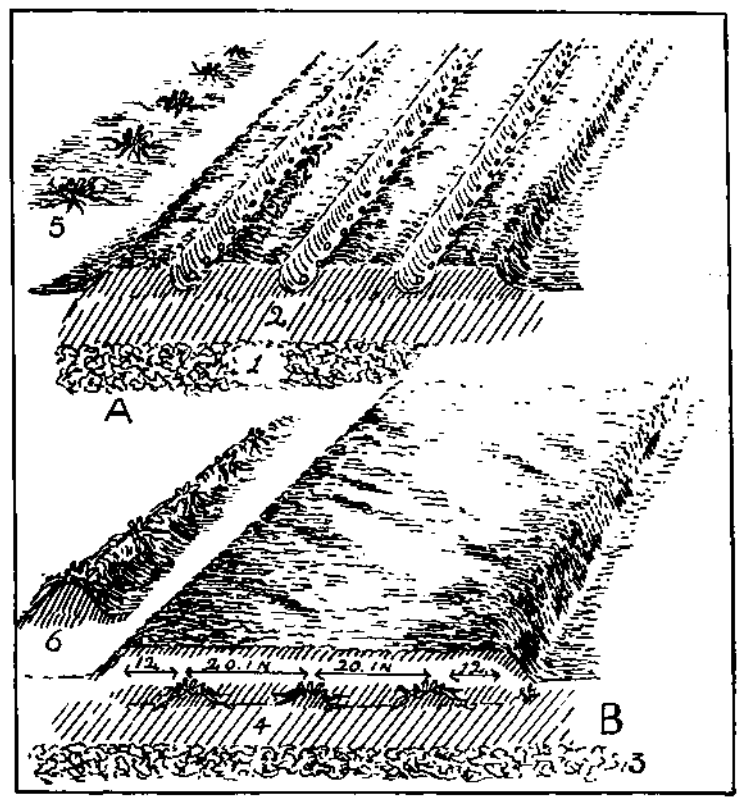
GLOBE ARTICHOKES.—It is usual to protect the old plants with leaves or litter during the winter. It may be remarked that such material left round the plants a day longer than is necessary weakens them. Remove it forthwith and any outside seared leaves and stalks of the plants. Surface dress with rotted manure and lightly fork it in. When the first stems appear apply a good soaking of liquid manure.

Sow seeds, also, as soon as the soil can be prepared, dropping several 3ft. apart in shallow drills 3ft. 6ins. asunder. Dig the soil deeply.

JERUSALEM ARTICHOKES.—To obtain the best crops prepare the soil as carefully as for potatoes. Plant whole, fairly large tubers 18ins. between each in rows 3ft. apart in an open situation. The plants should be hoed regularly and a big percentage of cooking-sized tubers will result. The white variety is the best.

ASPARAGUS.—Two generations ago more trouble was taken with this crop than at the present time, but not with more satisfactory results than now. Elaborately-formed and expensive beds do not always yield the finest produce. The cold, heavy dressings of manure are rarely put on during the winter, but thinner layers of lighter material. All such coverings should be removed, and the soil between the beds forked up lightly so that the fleshy roots are not disturbed. Early lettuces or radishes may, meanwhile, be grown in the alleys.

NEW BEDS should be formed and planted towards the end of the month in the south, and in April in the north. Sow seeds, also, if preferred to plants, about the dates named. Figure A shows at No. 1 how the lower soil should be well broken up and enriched with manure; No. 2 shows the portion of soil into which the roots of the young plants will enter at an early date and so well rotted manure should be used here with finer soil about 4ins. from the top free of manure, in which the seeds should be sown 3ins. deep in drills 20ins. apart. Figure B illustrates how roots should be planted. The distance between the rows should be 20ins. in this case, also, and about 16ins. from root to root in the rows. No. 3 shows the lower, well prepared layer of soil; a thorough breaking up of the stiff loam being important, while one observes in No. 4 the layer, fully 1ft. deep, enriched with rotted manure and the roots planted on small ridges 20ins. apart and about 4ins. deep. Where beds are formed the outside rows of



FIGURES ILLUSTRATE HINTS IN THE CULTIVATION OF ASPARAGUS.

Digitized by Google

plants should be 1ft. from the edges to avoid the eventually undue exposure of the roots. Between every third and fourth row, and, between every bed, the alley should be 2ft. wide. Overcrowding of asparagus is a mistake as it results in weakly, almost worthless, growth. No. 5 shows the wrong way to plant the roots, while No. 6 illustrates the correct method. The formation of the tiny ridges may entail a little more labour, but the results warrant it, as in naturally moist soils the crowns do not sink in and decay. Connover's Colossal is a fine variety.

BROAD BEANS.—In heavy soils the plants do well if raised from seeds sown now, as they grow without check. Beck's Gem, dwarf, should be dibbled into shallow holes 6ins. apart in the rows and 1ft. from row to row. Early Mazagan should be similarly planted, allowing 3ins. more space between the rows. Green Windsor is also a fine variety and Seville Long Pod is not only early, heavy cropping and of fine flavour, but has pods of great length. For this and similar sorts allow 2ft. between the double rows and 8ins. between the seeds.

EARLY CAULIFLOWERS.—All autumn plants raised and wintered under glass should be fully exposed every day and the lights tilted every night. The latter should be removed altogether at the end of the month. Spring-raised plants will require more careful treatment in cold frames, but free ventilation night and day in fine weather and their final planting will be due about the middle of April. Early Snowball, Magnum Bonum, Erfurt Dwarf Early (Walcheren for mid-summer), Eclipse and Veitch's Autumn Giant for latest supplies are recommended.

BRUSSELS SPROUTS.—The autumn-raised plants will mainly yield sprouts from October to Christmas. A sowing of seeds in the open border will be necessary now, the resultant plants being available for sprouts from January to March next. Aigburth, Dalkeith and Scrymger's Giant all bear freely very fine sprouts.

SPRING CABBAGES.—The plants from an early sowing this year will require similar treatment to early cauliflowers, with the difference that a transplanting now in an open nursery bed for one month will fit the plants for their open quarters in the latter part of April. The soil should be hoed between the rows of the autumn-raised plants every week in fine weather.

Enfield Market, Little Pixie, Large York, and Improved Nonpareil are all good varieties to grow from spring-sown seed.

ONIONS.—The cultivator will now be anxious about the sowing of seeds in the open quarters and the treatment of box-raised seedlings. The soil will be in readiness, of course, for seed sowing, all except its surface preparation. Having raked the soil thoroughly and working into it a fairly liberal application of old soot and dry wood ashes, drills should be opened about 9ins. apart for the general crop and 1ft. asunder for a special one and the seeds sown in them thinly. Cover the seeds 1in. deep and finish the work by raking the soil in the same direction as the drills run—not across them. Ailsa Craig should be included for the supply of large bulbs; also Cranston's Excelsior; Bedfordshire Champion, Up-to-Date, White Spanish, very mild; Rousham Park Hero and James are beneficial for storing purposes. The plants raised in boxes should now occupy a cold frame and be hardening for the final planting-out in April.

VEGETABLE MARROWS AND CUCUMBERS.—For the maincrop supply, seeds should be sown in small pots in a frame. The resulting plants should be grown on steadily, as weakly specimens are almost worthless. The chief care should be to water carefully and prevent a check to growth. Young cucumbers should be subjected to more heat and moisture. A nice batch of these plants will be appreciated when the frames are cleared of their winter and spring occupants, such as half-hardy annuals and bedding-out plants. The Bush Marrow, Long White, Long Green, Moore's Cream and Pen-y-byd are all good. Telegraph, Tender and True, Blue Gown and Model are fine varieties of cucumbers with Prolific Ridge for the open bed.

TOMATOES.—These plants should be potted and planted out under glass as required and those for open quarters potted on and grown sturdily, keeping them safe from night frosts in frames or houses. Holmes' Supreme, Kondine Red, Sunrise, Ailsa Craig and Best of All are splendid free-fruiting varieties.

PEAS.—Readers are referred to our issue for February 9th, page 74, for notes in detail on garden peas.

SMALL SOWINGS should be made, only, of the following kinds this month, namely: Carrots (stump rooted), turnips, lettuce, spinach, French beans under glass. The maincrop celery should be sown, and the trenches for leeks and celery formed as the soil will be improved by exposure to air.

A SELECTION OF VARIETIES FOR SMALL GARDENS.

Asparagus, Connover's Colossal; broad beans, Broad Windsor; Brussels sprouts, Dalkeith; cabbage, Ellam's Early; cauliflower, Magnum Bonum; celery, Sulham Prize Pink; cucumber, Telegraph; leek, Improved Lyon; lettuce, All-the-Year-Round; onion, Rousham Park Hero; parsnip, Student; peas, Gradus, The Gladstone, Laxtonian; potatoes, May Queen, Arran Comrade, Majestic; radish, French Breakfast; spinach, Round-seeded; tomato, Sunrise; turnip, Snowball; vegetable marrow, Moore's Cream. The above selection applies to vegetables that should be dealt with during March and for gardens where not more than one or two varieties can be found room for.

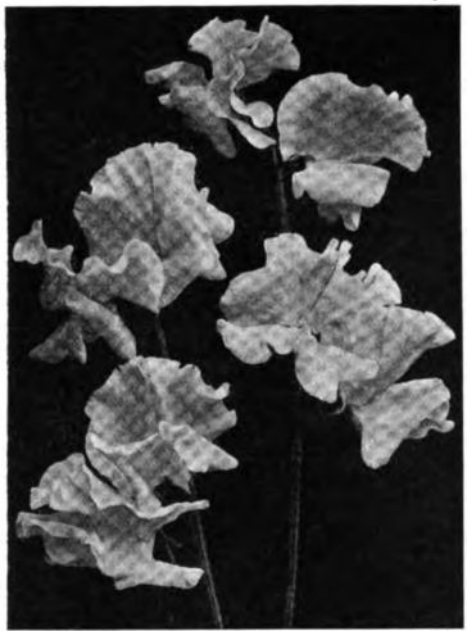
SWEET PEA CULTURE

BY DONALD ALLAN.

THOSE who have not already sown their sweet peas should do so without delay. For exhibition peas sow two seeds in a small 60 pot in a mixture of one part old loam, one part leaf-mould, with a little sand added to keep the soil sweet. Place one small crock in the bottom of each pot with a little rough leaf-soil on the top to act as drainage. Fill up the pot to about one inch from the rim. Place two seeds in a pot and cover with about half an inch of soil, pressing firmly with the thumbs, but on no account make the soil hard. Leave a little loose soil on the top, as this absorbs the water and prevents the soil from getting sour. Now place the pots in a cool greenhouse, if possible, until the seedlings are just seen pushing their way through the soil; then remove to a cold frame immediately, as the young seedlings must not get drawn or weakly. Keep the lights on the frames for the first week, but after three days admit a little air in the daytime by tilting up the lights at the back about three inches. Close down every night. After the first week the lights can be removed altogether in the daytime, unless in very cold or wet weather. From now onwards the plants should be encouraged to grow away freely. As soon as they show their third pair of leaves the top should be pinched out. This will encourage strong side growths, which later on will form the main leaders. The plants, if gradually hardened off, should be ready to plant out in their flowering quarters about the middle of April, if the soil is in good working order. Do not work on the ground until it is fit, as there is nothing to be gained by hurrying if the land is wet and sticky, rather postpone the planting for a day or two. Very good results can be obtained by sowing the seed in boxes in rows and germinating in the same way as recommended for seed sown in pots.

The trench in which they are to grow should have been prepared in the autumn, but if this has not been done proceed at once to dig out a trench 2ft. wide and 2ft. deep. Some growers recommend digging the trench 3ft. deep, but I do not consider this is necessary. Stretch a line along where you propose digging your trench, running north and south for preference. Dig out the top spit and place it on the right-hand side of the trench, then dig out the bottom spit, placing it on the other side. Now scatter crushed bones along the bottom at the rate of a 6o potful to every four yards of trench. Fork this into the bottom, about four inches, and leave the soil rough. Then spread about three inches of well rotted cow or pig manure if the soil is at all light. Bear in mind that the manure for a spring trench must be old and well decayed. Fresh or rank manure is all very good for an autumn-dug trench but is too strong for spring work. If the soil is inclined to be heavy, a little stable manure should be mixed with the pig or cow dung. Failing stable manure, some rough leaf-mould or old garden refuse will do equally well. Commence to fill in the trench by shovelling the top spit back in the bottom, that is, the spit which was placed on the right-hand side of the trench. When this is finished, fork the bottom up to incorporate the manure and the soil well together, taking care not to go too deep to disturb the crushed bones, as they must be left right at the bottom of the trench. I do not recommend putting the manure in in layers, as I have found the roots get a check in coming into direct contact with a solid mass of manure, which is the cause of the lower leaves turning yellow and the plants getting a sickly appearance. Now fill in the spit placed on the left-hand side of the trench until the whole trench is completed. Give a good top-dressing of burnt wood ashes or burnt garden refuse to each trench

Digitized by Google



THE DEEP CREAM PINK VARIETY, PICTURE.

and fork in about three inches. If there is no burnt material at hand, dress the top of the trench with potash, about a 6o potful to every four yards, and leave it lying until the day before the sweet peas are planted, when it should then be forked in lightly. Sweet peas for exhibition should be grown on canes, bamboo canes for preference, as these last longer.

Commence to plant along the centre of the trench, placing the pots where they are to be planted one variety at a time. In this way the colours cannot get mixed. It is also necessary to have a few spare plants of each variety to be kept in reserve for any blanks that may have to be made up by the ravages of birds, mice, slugs, etc., and care must be taken not to mix them while in the frames. There should now be four leaders to be trained up from each pot, which can be carefully drawn over and secured to the canes on opposite sides of the trench. My reason for planting in the centre of the trench is that it is much easier when mulching time comes to push the manure into the roots of the plants without damaging the foliage than it would be if planted in a double row, as well as giving the young plants more root room before touching the sides of the trench.

For those who have sown their seed in boxes the plants must be carefully lifted from the box with a small handfork. First remove the end of the box, then the fork can be slid under the plants without injury to the roots. Shake out carefully and plant in the centre of the trench. This time there will be two leaders to be trained up the cane, one on either side of the trench.

When all the planting is finished, I would advise that the canes be got into position as soon as possible, placing them 6ins. apart and securing them to the wires which have been erected on the framework. This will help to protect the young plants from the cold winds. They must now be carefully watched, as slugs very quickly attack the young plants. To prevent this give each row a good dusting of lime, and what I have found to be a good plan is to plant an early row of lettuce between the trenches, as this often attracts the slugs from the peas.

In about three weeks the young growths will require attention, and any long enough must be tied to the canes to prevent them from being blown about and damaged by the wind. From now onwards they will require to be gone over at least twice a week to be tied up to the canes. Hoe along the rows occasionally to kill all weeds and keep the soil from cracking. If the plants are healthy and doing well, they should be showing flowering buds when they are about three and a half feet high. Now is the time to feed them with doses of weak liquid manure from the farmyard or from sheep droppings put into a bag and soaked in a tank or tub of water. Use this once a week to begin with, 1 pint to 3 gallons of water, applying a little stronger twice a week as the plants get older. Give the trenches an occasional dusting with Dobbie's Special Fertilizing Compound, and wash in with clear water, or it can be given in liquid form, 1oz. dissolved in a gallon of water. I have omitted using soot until now because I find it has more effect in giving rich colour to the blooms when used in liquid form after the plants have commenced flowering.

A CHARMING BLOOM OF HAWLMARK PINK.

The twenty-four most popular varieties for exhibition or garden decoration, all strong growers which can be grown on two leaders with excellent results are: Constance Hinton, undoubtedly the best white; Picture, deep cream pink; Royal Scot, scarlet; Mrs. Tom Jones, the best blue; Majestic Cream or Matchless, the best creams; Hawlmark Salmon Pink, deep pink; Royal Purple, best purple; Charity, crimson; Dignity, cream pink; Hawlmark Pink, deep dainty pink; Warrior, dark maroon; Elegance, blush lilac; Royal Sovereign, orange; The Sultan, best black maroon; George Shawer, giant salmon rose; Austin Frederick Improved, lavender; Doris, rose cerise; Jean Ireland, cream ground, picotee edge; Advance, white ground, flushed with rose pink; Valentine, blush pink; Gladys or Powerscourt, lavender; Youth, greatly improved Dobbie's Elsie with picotee edge; Renown, carmine; and Crimson King, crimson.

The best twelve: Constance Hinton, Royal Scot, Mrs. Tom Jones, Youth, Royal Purple, Charity, Hawlmark Pink, Royal Sovereign, Austin Frederick Improved, Renown, Doris and Matchless.

MAINTAINING A LAWN

BY A. OSBORN.

CONSTANT attention is necessary to maintain a lawn in good condition. The important items in the upkeep of a lawn are rolling, mowing, weeding and manuring. Most lawns are carefully mown and rolled, a fair number are weeded, but comparatively few are systematically manured. Each succeeding year, from spring to autumn, the grass is frequently in need of manuring. How many owners of lawns pause to consider how much plant food is taken from the ground by grass?

The occasional application of manure to a lawn need not interfere with its enjoyment. Except for the possible use of a little artificial manure during rain in summer, the application of manures to lawns should be done between October and February. The best of all manures for a lawn is a thin sprinkling of rotting stable manure during late autumn. Brushed or raked at weekly intervals, this will eventually disappear. Comparatively few readers will be in a position to use stable manure. Basic slag is one of the cheapest and most useful manures for grass. Apply a broadcast dressing of from 4cwt. to 8cwt. in autumn or early winter. This is a good manure to apply to soils deficient in lime. For soils containing plenty of lime, superphosphate is a good manure for application in spring, at the rate of from 2cwt. to 4cwt. per acre. Sulphate of ammonia is a useful lawn manure for spring application, using from 1cwt. to 1½cwt. per acre.

In a garden and its surroundings there is usually plenty of material available which, if systematically collected and stored, will provide an excellent dressing for lawns in early winter. The first item may be the old potting soil from the greenhouse, chrysanthemums, tomatoes, etc., weeds from the flower beds and vegetable plots, leaves, lawn mowings, manure from the poultry pens, the rabbit

Digitized by Google

hutches and the pigeon lofts, will all be very valuable. Rubbish and sticks from the garden which will not readily rot can be burnt and the ash added to the heap. From time to time the heap should be turned over, adding lime, which improves the physical nature of sour soils and releases ingredients in the soil. It is desirable to commence a fresh heap of refuse about April in each year. The collection of the previous twelve months, if left to rot from April to September without adding any fresh material, will be ready for use in October. Whether the top-dressing is first passed through a sieve or applied straight from the heap to the lawn, and the refuse raked and brushed from the grass later, is a matter of choice.

Most manufacturers of manures prepare a special grass fertiliser. For the busy man who takes a pride in his small lawn, mowing, rolling and weeding it with care, this manure provides a very simple and easy means of maintaining a first-rate lawn. Special preparations are also on the market for destroying weeds on a lawn, such as a fertiliser to apply to lawns infested with clover (encouraging the growth of the finer grasses while checking that of clover), and also a worm-killer to apply when worm casts spoil a lawn.

RENOVATING A LAWN.

Poor, patchy turf or worn grass on a lawn can usually be traced to one of four causes: poor soil, badly drained ground, continued hard usage of a small area (*e.g.*, the nearest point of the lawn to a door or a short cut across the grass between two points), or failure to manure the lawn.

There are two ways of dealing with thin turf and bare patches of a poor soil. Lifting the turf, digging and enriching the ground, replacing the best of the old turf and making good the shortage by purchase, or lifting turf from elsewhere in the garden. If there is a prospect of rejuvenating the grass without such drastic treatment, there is the remedy of thoroughly loosening or pricking the surface soil, adding rich soil, wood ashes and manures. If the surface of the ground is not too hard, vigorous raking and cross-raking with an iron-toothed rake will loosen the soil. Failing this, lightly prick over the surface with a digging fork, whether there is grass or not, but, obviously, paying special attention to the bare patches.

Having thoroughly loosened the surface, sow seeds thinly or thickly according

CAREFUL LEVELLING WITH "BONING RODS."

to the state of the turf. Rake over the surface again, this time using, for preference, a short-toothed wooden rake. Prepare a rich compost of sifted soil, and proceed to cover the surface with a thin layer. If only a small area is involved, scatter with the hand. For large stretches of ground, use a shovel. The rich compost may be made up of old potting soil from the greenhouse, manure from a spent hot-bed or mushroom-bed, old turfy loam mixed with superphosphate; while, on heavy ground, sand also should be added to the top-dressing. Complete the operation by rolling with a light roller.

AN UNEVEN SURFACE.

To lift and relay the turf because of its worn and patchy appearance, commence by cutting the turves into 1ft. squares as indicated in Fig. 2, using a 10ft. or 12ft. rod and a turfing iron. To facilitate relaying, it is important that the turves should be all of one size and equal thickness. Unless otherwise stated, when turves are purchased they are 3ft. long and 1ft. wide. For convenience in transit they are rolled. It is easier, when lifting and relaying turves at home, to keep them flat, 1ft. square being a useful size. The flat lifting tool with a cranked handle in use at Fig. 3 is known as a turfing iron.

Having cleared the surface of turf, the ground should be forked over, digging in any available rich soil, old decayed manure, wood ashes, etc. Fresh manure should not be dug in, as, when this decays, almost invariably the ground sinks and leaves the turf uneven. After digging, tread and rake the surface well, so that it is firm and not liable to sink into holes. Then proceed to lay the squares of turf as depicted in Fig. 4. The wooden tool with a flat bottom is known as a turf-beater. It is fairly heavy, being made of oak, and is used to firm the turves after laying. Spread a thin layer of finely sifted soil over the surface and brush it to fill in any cracks that may occur between the turves. Complete the work by rolling with a light roller.

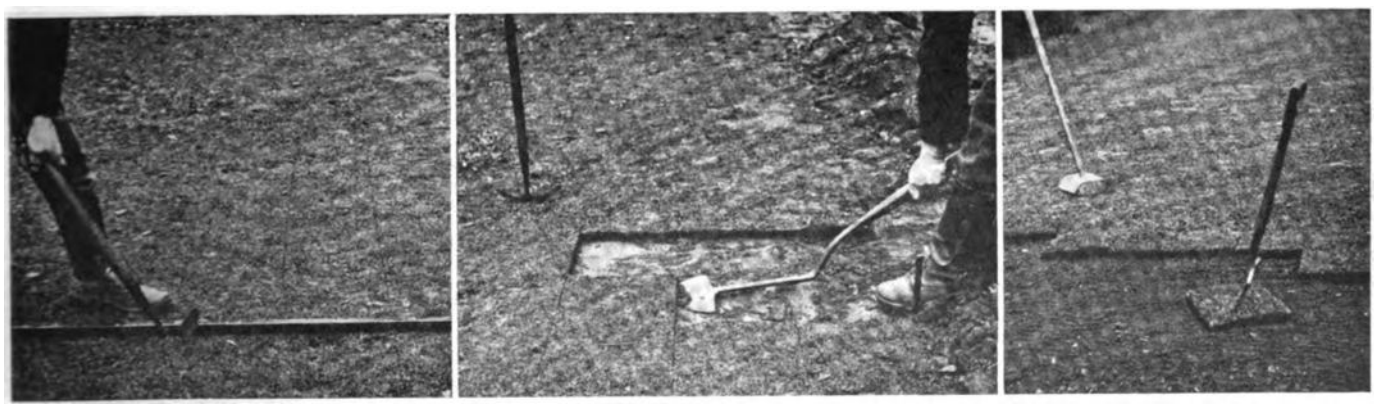
SOWING GRASS SEEDS.

The question of turfing a lawn or sowing seeds is usually decided by the problem of £ s. d. The turf is ready for use in a few weeks, while the sowing of seeds is infinitely cheaper, but is unfitted for hard wear the first season.

Levelling the ground previous to sowing must be carefully done. Small areas and ground for tennis courts, bowling greens and croquet lawns are readily levelled with pegs driven in the ground, a straight-edge and a spirit-level. For large areas pegs are again used, with "boning rods," as indicated in the illustration, Fig. 1.

In digging over the ground for a lawn, the soil must be broken down into fine particles, as otherwise it will settle with an uneven surface. Tread and rake the surface, removing stones and hard lumps of soil to obtain a fine tilth. The end of March or early April is the best time for the sowing of grass seeds in spring.

The amount of seed sown per square yard may be varied on the score of expense and whether a good turf in the shortest possible time is the main object. For ordinary sowing, 1 oz. per square yard will suffice, but, for quick results, up to double this amount may be sown. Choose a dry, calm day for sowing. To assist in securing an even distribution of the seeds, divide the ground into 2yd. widths, using a garden line, and bringing it forward as each stretch is sown.



THE CUTTING, LIFTING, AND LAYING OF TURVES, SHOWING TOOLS EMPLOYED.

THE FIRST SPRING SHOW AT VINCENT SQUARE

THERE was no falling off in either the number of exhibits or the attendance at the fortnightly meeting of the Royal Horticultural Society at Vincent Square, Westminster, on February 26th. During the greater part of the afternoon there was almost an uncomfortably large attendance, and most of the exhibits were of considerable interest.

Among the floral groups the chief was that of superb bulbs grown in bowls of fibre, shown by Messrs. R. H. Bath and Co., and this deservedly received the highest award of a gold medal. The Dutch tulips were of splendid quality. Besides tulips there were daffodils, hyacinths and crocuses of equally high merit. Along the sides of their exhibit Messrs. Bath placed pots of Fritillaria Meleagris.

On an adjoining table Messrs. R. and G. Cuthbert set up a quantity of mollis and Ghent azaleas of warm glowing colours.

Indica azaleas were contributed by Messrs. L. R. Russell, Limited, also some smaller pots of the beautiful little Japanese varieties.

Mimosas in variety, with the comparatively rare Coleus thyrsoideus and some good hippeastrums, were staged by Messrs. Stuart Low and Co. next to their large collection of greenhouse carnations.

Messrs. Allwood Brothers had their usual group of first-rate carnations and, of course, many vases and bowls of their charming Allwoodii, which in their hands seems to be as perpetual as their larger sisters. Their perpetual border carnations, which combine the formal beauty of the old florists' flower with the continuous blooming habit of the newer type, were much admired. Mr. C. Engelmann had many useful varieties in his collection of carnations. Messrs. Cragg, Harrison and Cragg showed another collection of their excellent strains of blue and pink cinerarias.

Mr. George Paul staged a further collection of bushy camellias. The Swan and alba simplex are two good single whites. The alternating scarlet and white petals surrounding the anemone-like centre of C. Gilesi is very attractive.

Roses were staged in larger quantities and of better quality than most visitors would have expected so early in the year. Mr. Elisha Hicks included vases of Climbing Lady Hillingdon; Glory of Hurst and Lady Reading are two good red cluster varieties.

Glorious sprays of the difficult Fortune's Yellow Rose were shown by Mr. George Prince, who also demonstrated his great ability with the yellow Banksian rose, of which he had long sprays smothered in flowers. Among his H.T. varieties were good vases of Richmond and Golden Ophelia. Messrs. Sutton and Sons had a few charming bowls of their large-flowered star primulas, which were highly decorative. Mr. B. Pinney again showed large-flowered violets.

Alpines were mostly saxifrages, though various primulas and hardy cyclamens were to be seen in many exhibits. Messrs. M. Prichard and Son had Primula cashmeriana and Saxifraga oppositifolia major in fine clumps. Several very desirable varieties of the hardy cyclamen were included by Messrs. Carter, Page and Co. in their collection of alpines. Mr. F. G. Wood and Mr. G. W. Miller both had pots of the delicate blue Grape Hyacinth, and the latter showed many of his excellent polyanthuses and primroses.

A very complete little collection of seasonable border and alpine flowers was contributed by Messrs. Barr and Sons, who included various dwarf irises, primulas, early little daffodils, lachenalias and some hellebores bearing sombre yet interesting brown and blackish flowers. A small rock garden was made by Messrs. J. Cheal and Sons, who also set up a good collection of Dielytra spectabilis. The brilliant scarlet flowers of Tulipa præstans, a double red daisy and many crocuses were displayed by Messrs. Waterer, Sons and Crisp. An interesting collection of alpines in which saxifrages predominated was arranged by Messrs. R. Tucker and Sons.

Hardy shrubs in variety added considerably to the interest of the Show. Messrs. Wallace and Co. staged dwarf conifers, a pretty little standard of the true Tarantine myrtle, Daphne Mezereum album, with Andromeda japonica and Berberis japonica bearing ample racemes of flower.

Various olearias and dwarf conifers suitable for the rock garden, were shown by the Orpington Nursery Company. Messrs. Maxwell and Beale had dwarf heathers. Large-foliaged rhododendrons, Abies Webbiana and various alpines were staged by Mr. G. Reuthe. Floriferous bushes of Forsythia were prominently placed by Messrs. Skelton and Kirby. Viburnum Carlesii in quantity was arranged over such primulas as the pink form of P. denticulata by Messrs. Bakers, Limited.

Many spathes of Richardia (arums) were brought by Messrs. R. Gill and Sons, with excellent sprays of Erica codonoides and a mass of Primula Juliæ.

The only collection of vegetables was one of the splendid exhibits by

THE KALEIDOSCOPIC EFFECT OF THIS TABLE OF BULBS, SHOWN BY R. H. BATH AND CO., CAN BE IMAGINED.

Digitized by Google

Messrs. Sutton and Sons. They displayed practically every seasonable kind, including mushrooms of the highest quality. The heads of Broccoli Snow White were perfect in form and of milky whiteness. Dwarf beans were freely shown and of such sterling sorts as Sutton's Early Giant, Plentiful, Superlative and Masterpiece, and all were so well grown that none could be singled for special mention. The seakale was probably the best ever seen at a show.

Messrs. George Bunyard and Co. had a dozen dishes of apples of brilliant colouring of such sorts as Crawley Reinette, Sanspariel and Mabbott's Pearmain. Messrs. Shearns, Limited, had another of their "shop windows," in which they displayed excellent fruits and cinerarias.

NEW AND RARE PLANTS.

CANARINA CAMPANULA. — Although this interesting greenhouse perennial was introduced from the Canaries (hence its generic name) so long ago as 1696, it is a very rare plant in this country. A decade or more ago the late Mr. H. J. Elwes brought a small specimen to the R.H.S. hall. About a score of years ago Mr. E. J. P. Magor of Lamellan, St. Trudy, Cornwall, collected seeds of the canarina and distributed seedlings in the West of England. With these exceptions the plant does not seem to have been much grown. A well grown plant possesses considerable attractions. The solitary, terminal, pendulous, bell-shaped flowers are unusually large for the natural order Campanulaceæ, and the purplish-fawn ground colour is relieved by the reddish veins. Canarina campanula thrives best in quite a cool greenhouse and when it can be planted out in a light rich soil placed on the staging. This ensures the perfect drainage

GRACEFUL SEEDLING OF IRIS LITTLE BOY BLUE.

which is needed; copious waterings are essential during the growing season. A large, well grown plant was exhibited. Award of merit. Shown by Lieut.-Colonel Messell.

FREESIA FLAME.—The colouring of this deliciously fragrant variety might almost be termed "butter and eggs," for it is a deep yellow (almost a buttercup yellow) splashed with deep orange. It is a very desirable novelty of robust habit. Award of merit. Shown by the Rev. Joseph Jacob.

IRIS LITTLE BOY BLUE.—A pretty little Krelagii seedling only a few inches high, but of good size and metallic blue colour with a gold crest. Award of merit. Shown by Messrs. H. Chapman, Limited.

LACHENALIA RUTLAND.—This is a charming novelty of very uncommon colouring. The large, well formed flowers are broadly rimmed with rosy maroon which is distinctly lighter on the edge of the segments. The unopened buds and the tips of the flower-stalks are brightly flushed with purple. The remainder of the stout flower-stem is pea green in colour with occasional cloudy maroon marking. Award of merit. Shown by the Rev. Joseph Jacob.

LACHENALIA SIAM.—This is another good variety with large flowers. They are a bright buttercup yellow and of waxy texture. The flower-stems are yellow. Award of merit. Shown by the Rev. Joseph Jacob.

ORCHIDS.

FIRST CLASS CERTIFICATE.

MILTONIA WILLIAM PITT VAR. ROSSLYN (M. Isabel Sander × M. Bleuana var. Reine Elizabeth), exhibited by Mr. H. T. Pitt, Stamford Hill, London. Undoubtedly the finest Miltonia hybrid yet seen. It belongs to the well known vexillaria section, but differs in its glorious ruby-crimson colour which covers the whole flower, except for the lemon-yellow mask at the base of the labellum.

AWARDS OF MERIT.

ODONTOGLOSSUM LEANDER (parentage unknown), from Mr. R. Gerrish, Milford Manor, Salisbury. One of the finest of the amabile section, the large flowers having the segments broadly formed and effectively marked with rose-purple.

ODONTIODA PURPLE EMPEROR (O. Coronation × O. Armstrongii var. Peerless), from Messrs. Armstrong and Brown, Tunbridge Wells. A most promising seedling, bearing a couple of flowers, the segments broad and flatly displayed, deep violet-rose in colour, with solid claret-red blotches on the central area.

CORRESPONDENCE

INBREEDING OF RHODODENDRONS.

I HAVE read with much interest your correspondence on the self-pollination of rhododendrons. It is unfortunate that a caucasicum hybrid has been used as an illustration, for although valuable and first-class crosses have been made with caucasicum, the result of this blood is to render the hybrids sterile in many cases. Seed, I believe, has never been known to set on nobleanum, for example.

Unfortunately, the time taken to raise and flower rhododendron seedlings is usually too long for them to have been worked out on Mendelian lines. It is well known, however, that certain rhododendron hybrids, where the two first parents are species, will come true in the next generations, *e.g.*, the rhododendron which in Cornwall is known as Dickson's Aucklandii will come perfectly true from seed both as regards foliage and flower and with apparently similar vigour. It is, of course, absurd to attempt to raise seedlings of the ordinary garden hybrid with the hope of getting anything but a reversion to the dominant factor, but seedlings raised from some of the choicer hybrids (species × species) in Cornish gardens have produced good strong seedlings which in leaf character show resemblance to the parent plant but which have not yet flowered.

It may be, however, that while a rhododendron will not reproduce healthy plants if the flower is self-pollinated, it will produce good results if the flower is pollinated from a different flower on the same plant. Auriculatum is well known as being very shy of setting seed, possibly due to the fact that the humble-bee has by August taken to searching other plants for honey and leaves the rhododendron alone, but on a big plant of auriculatum covered with flowers in my garden I self-pollinated one truss with pollen from its own flower, the truss next to it was fertilised with pollen taken from a truss on the opposite side of the plant, and some half-dozen trusses I left to Nature. The self-pollinated truss and those left to Nature failed to set seed, whereas I got three or four good seed pods from the flower fertilised with pollen from the other side of the plant, from which seedlings have been raised. I do not believe the theory that the humble-bee when it attacks a flower self-pollinates it. One speck of pollen is sufficient to throw a pollen tube, and I think that the humble-bee, although it will have plenty of pollen from the flowers it has just been to, will yet always have sufficient strange pollen to predominate and to throw a stronger tube on the pistil and that cross-fertilisation is very much more frequent on these plants than Mr. Stevenson imagines. To prove this, I have often seen humble-bees going from truss to truss of R. Souliei in my garden and, according to the first article, although the first flower should have been cross-fertilised, yet every other flower on the species should have been self-pollinated with pollen from the same plant. Now Souliei is one of the rhododendrons that is very easily affected by foreign pollen, and anybody who has tried to raise seedlings of this plant, as I have done, knows the difficulty of raising it true even if many pods are picked on the same plant with the idea of weeding out the rogues later on, and in the two attempts that I have made I failed to get a single true specimen in some hundreds of plants, and I believe that the only way to raise true plants of this species is by artificial pollination, taking care that strange pollen should not reach the pistil. I think you are to be congratulated on opening your columns to such a very interesting subject, and with apologies for my meagre remarks.—LIONEL DE ROTHSCHILD.

RCCK GARDENS UNDER GLASS.

THE notes by Mr. Low in THE GARDEN of February 16th, are very interesting to those who have suitable accommodation for these fascinating plants, and recall to my memory a small house devoted to alpines of which I had charge of some years ago.

Digitized by Google

Many of the plants one sees growing in an outdoor rockery would scarcely be recognised when seen in flower under the protection of a glass roof. The flowers open much cleaner and brighter, especially of the varieties which bloom in the early months of the year. During open weather a house devoted to alpines cannot possibly have too much ventilation. The majority of the varieties being quite hardy they cannot stand "coddling," and should be grown as sturdy and naturally as possible.

If a house is arranged as a rockery, suitable spaces should be allowed between the rocks for batches of plants which have been grown in pots to be planted, or plunged, just as they are coming into flower. Then one can always have an attractive show. To take an instance, primulas grown in pots in a cold frame—such as japonica, Bulleyana, pulverulenta, Juliæ, and the less hardy malacoides, and obconica—may be planted, and a magnificent show will result. To plant an indoor rockery fully is to my mind disappointing at times when plants have finished blooming. There are too many dull spaces, whereas if suitable plants are grown in pots in a cold frame and brought in when coming into flower, the house can always be kept bright and interesting. Varieties which I consider most suitable for permanent planting are those which are evergreen, such as sedums, saxifrages, aubrietias, dianthi, gentiana, etc. These are always neat and attractive, even when not in flower. In the spring the rockery can be kept bright with different bulbs grown in pots, and planted out in suitable places.

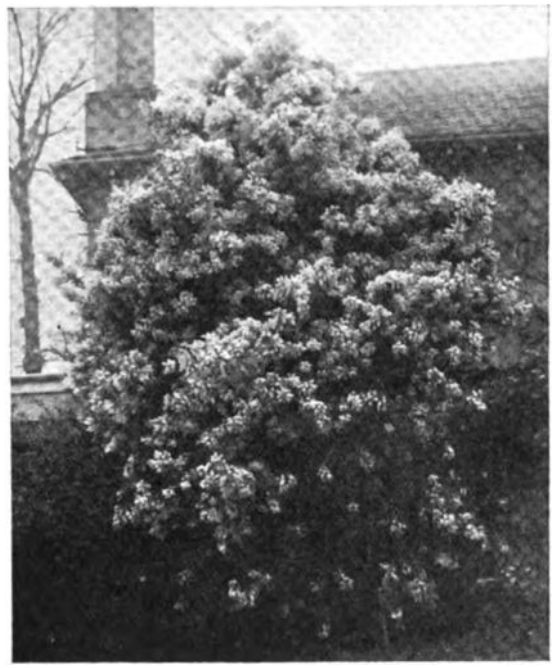
The following are a few varieties I can recommend as fairly easy to grow, although all, of course, are not evergreen. Androsace Chumbyi, Anemone Pulsatilla, A. P. alba, Antennaria tomentosa, Armeria plantaginea rosea, Aubrietia Dr. Mules, A. Fire King, A. Prichards A. 1, Borage laxifolia, Campanula carpatica Riverslea, C. pulla, Cypripedium spectabile, Dianthus neglectus, D. deltoides, D. roseus, Dryas octopetala, Gentiana acaulis, Helianthemum Scarlet Queen, H. The Bride, Hutchinsia alpina, Iberis gibraltarica, Ourisia coccinea, Phlox divaricata Laphami, P. G. F. Wilson, P. Moerhoemi, P. Bijou major, Primula cashmeriana, P. pulverulenta, P. Bulleyana, P. Juliæ, Saxifraga apiculata, S. Aizoon rosea, S. Faldonside, S. decipiens Bakeri, S. Bathoniensis, Sedum Ewersii, S. Nevii, Silene Schafta, Thymus coccineus, Verbena chamædrifolia, V. venosa.—ALFRED GREAR, *The Old House Gardens, Walmer, Kent.*

CAMPANULA LINIFOLIA AT MONT CENIS?

THE Campanula linifolia referred to in my notes on plants at Mont Cenis is not C. linifolia (Scopoli) as figured in Thompson, but C. linifolia Lamarck, which seems to be very similar to C. Scheuchzeri, Villars. These, along with C. carnica and a host of others, are included in Farrer's "English Rock Garden" under C. rotundifolia as forms of that species, most of them according to his experience reverting to a more or less typical C. rotundifolia when planted out in this country. The flowers at Mont Cenis were of a deep satiny violet colour, larger and a much more robust plant than any form of C. rotundifolia that I have seen in this country. It is interesting to note that in addition to the above C. linifolia that there is also C. linifolia De Candolle, which, according to Joseph Wood's "Tourists' Flora"=C. Scheuchzeri, Vill., C. linifolia, Hænke and C. linifolia, Gaudin, which are included under C. Scheuchzeri in Gremli's "Swiss Flora," and C. linifolia, Flahaut, as referred to by Mr. Enever Todd. Some of these may be due to the plants being described in the field after the radical leaves had died away as suggested by Mr. Todd.

My remarks on the absence of the fluffy seed heads of Anemone alpina resulted in a kind note from a correspondent, who said: "Your surmise about Anemone alpina is quite correct. On June 25th there was a great frost at Mont Cenis and the anemones which the day before had been at their best were literally razed to the ground. The leaves were blackened and the flowers withered up as though they had been burnt."—T. A. L.

I HAVE just picked up and read—having been away and so missed it until now—THE GARDEN, February 9th, in which Mr. E. Enever Todd comments upon the Campanula linifolia reported by Mr. Lofthouse from Mont Cenis. I collected C. linifolia at Mount Cenis with the late Reginald Farrer many years ago. I accepted the name from



A FINE BUSH OF ACACIA BAILEYANA OUTDOORS.

Farrer at the time, and have since found the same plant on the Galibier Pass and at Val d'Isere and elsewhere and have distributed a selected variety of it very widely over a number of years, and have also exhibited it frequently under that name and have never had the name questioned.

I must confess that I do not remember ever having gone very deeply into the question of whether it was the C. linifolia of Scopoli or of Flahaut. One of these days—if I have time—I will go and delve among herbarium specimens at Kew, though I doubt if any conclusions or confusions I may arrive at will add to my pleasure in growing the plant. The Mont Cenis, Galibier, Val d'Isere and elsewhere plant is certainly akin to C. rotundifolia. Possibly a mountain development. Yet it is distinct. I should be sorry to have to define the distinction in botanical terms. But for garden purposes, and although C. linifolia as I know it varies widely in colour, stature and even in the size and shape of the bell—for garden purposes it is quite distinct. Broadly speaking it is dwarfer, more solid in build of leaf, stem and flower, larger in flower and normally deeper in colour. In fact, just what one might expect C. rotundifolia to develop into under alpine conditions. I have found pale silvery lavender blue forms, and three summers ago I spent a whole Sunday on the Galibier, picking out the most lovely forms with gigantic bells of deepest purple. This linifolia has much the same narrow stem-leaves and roundish radical leaves as C. rotundifolia.

I rather feared that Mr. E. Enever Todd might quite likely have caught me—together with the late Rev. Johns—"deviating from the perpendicular" in the question of the apparent misnomer—C. rotundifolia. But I am glad to read in my edition of John's "Flowers of the Field," 1907—"The specific name, rotundifolia (round leaved), is far from being descriptive of the leaves which accompany the flower, as they are long and narrow, but is peculiarly applicable to the root-leaves, as they appear in winter and early spring, at which season Linnæus is said to have first observed them on the steps of the university at Upsala." I have not an earlier edition handy to see what was originally said on this point.—CLARENCE ELLIOTT, *Stevenage.*

ACACIA BAILEYANA OUTDOORS.

I ENCLOSE a photograph of an Acacia Baileyana growing in my garden. There are several beautiful specimens of A. dealbata in the neighbourhood, but so far I have not found this sort growing anywhere in the open, although I fancy it is the hardiest of the two and certainly the most beautiful. This one was planted in 1916 as a very small plant from a pot, and it must now be quite 19ft. or 20ft. high, and every year is a mass of fluffy yellow. It begins to blossom at the end of December and lasts from six to eight weeks in beauty.—VIOLET CAVENDISH BENTINCK, *The Cottage, Dawlish, Devon.*

FREESIAS AND DUDS.

IN reply to Mr. Jacob (page 51), I think he is carrying out my idea o ripening the corms by a slightly different method of his own. My reasons for saying so are that, speaking from memory, some seven years ago when duds first came under discussion, I humbly ventured to suggest that they were due to insufficient ripening. Time and my own methods have proved this to my satisfaction. Last year I gave Mr. Jacob rather full details as to how to treat his corms. Whether he treated any like I told him or not I do not know, but he has evidently carried out my ideas by a slightly different method of his own. Therefore what I mean is thus explained. My "cure" is proper ripening, and Mr. Jacob's is the same, though his *method* is not identically the same as mine. May I point out again that duds may occur, however well ripened the corms may be, if they get insufficient moisture after potting.—G. H. DALRYMPLE.

A CHARMING GRASS.

I WOULD like to add a little supplement of praise of the beautiful Arrhenatherum bulbosum fol. var. referred to by Mr. Joseph Jacob (page 74). I first saw this variegated-leaved grass growing in large clumps on the banks of a pond in a New Forest garden many acres in extent. It was one of hundreds of rare and interesting plants grown there. The plant is hardy, withstanding nearly 20° of frost without injury; but I also grow some under glass, where it attains a height of nearly 2ft., and is very useful for association with early sweet pea blooms. The peculiar freshness of the blades referred to by Mr. Jacob first drew my attention.—G. G.

GARDENING OF THE WEEK

FÓR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Onions.—The main crop should be sown without further delay, providing the ground is suitable for working. The soil is made firm by treading, and a fine tilth obtained by raking with a wooden rake. If available, a liberal sprinkling of ash from the rubbish fire will be beneficial, and it should be afforded before the drills are drawn. The lines should be from 9ins. to 12ins. apart. Do not sow the seeds too thickly or there will be a lot of work thinning out later on. Cover the seeds and then rake over the bed the same way as the drills; there is no need to firm the soil with the back of a spade. Suitable kinds are: Ailsa Craig, James' Keeping and Bedfordshire Champion. Plants raised in boxes may be hardened off and transferred to their final quarters, choosing if possible a rich and well tilled piece of land.

Leeks.—The principal sowing of leeks should be made, and from this batch a succession can be obtained by planting out the largest plants directly they are ready, and following on later with the smaller examples. Both the Lyon and Musselburgh can be recommended.

Peas.—The time has arrived when a good breadth of the marrowfat type of pea may be sown with every confidence of success. There are a host of varieties to choose from, but a good stock of Duke of Albany is hard to beat. True, its height is 5ft., but it yields fine crops, when provided with a suitable site. It is a good plan to allow them ample space, and then plant a few rows of potatoes, cabbage, spinach or lettuce between the lines of peas. To keep off birds and mice, damp the seeds with paraffin oil and then coat them with red lead. Sow thinly in flat drills about 6ins. wide.

Cabbage.—The bed should be hoed at intervals to keep down weeds and to encourage healthy growth. Fill up any blank spaces; the plants used will produce hearts a little later and, therefore, keep up the supply.

Carrots.—A few lines of Early Horn sown now will furnish roots to follow those from the frames.

THE FLOWER GARDEN.

Pruning Flowering Shrubs.—At this season a certain amount of pruning may be carried out. The late-flowering kinds of ceanothus and tamarisk, late-blooming spiræas such as S. japonica, S. Aitchisoni and S. Anthony Waterer, should be cut back. Jasminum nudicaule is cut hard back to near the old wood, and the same remark applies to Hydrangea paniculata. Caryopteris is treated likewise, and heaths may be pruned after flowering if they are getting large and spindly. In any case the old flower spikes should be removed. Ivy on walls and buildings can be trimmed as an opportunity occurs.

Annuals.—During March and April all kinds of hardy and half-hardy annuals may be sown in the open ground and, in most instances, where they are intended to flower. In all cases, sow thinly, and when large enough thin the seedlings so that they have ample room to develop.

Begonias.—The begonias to be used for bedding purposes may now be started into growth. Examine the tubers, and large examples may be cut into two or three pieces, but in such a way for each plant to possess two or three buds. Boxes should be filled with leaf-mould and the tubers partly covered, and then placed in a greenhouse or pit where the temperature is about 50° Fahr. Do not afford much water until the tubers are well started.

T. W. BRISCOE,
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Celery.—The seedlings from the earliest sowings should be set 2ins. or 3ins. apart in boxes filled with a good rich compost, and kept in a genial atmosphere until re-established in the fresh soil. An early vinery or early peach-house is almost an ideal place to set the seedlings at this stage, as the necessary heat, moisture and shade are here provided.

Onions.—Those contemplating sowing in the open should have the surface soil—when fairly dry—thoroughly broken down and well raked. Rows should be drawn out 2ins. deep and 15ins. apart, and the seed thinly sown. After covering the seed, rake lightly and go over the bed with a roller. The following well known varieties may be grown: James' Keeping, Magnum Bonum, Rousham Park Hero, Trebons and The Queen. The last-named is a quick-bulbing variety and, although small, is very fine.

THE FLOWER GARDEN.

Biennials.—The attractive Canterbury Bells and the salmon and pink shades of Sweet Williams should be set out in the borders. The plants are usually more effective when planted in small groups. Young plants of Agrostemma coronaria atrosanguinea, although perennial, should also be set out now.

Pink Mrs. Sinkins.—It is charming to have this old-fashioned plant in the garden. When plants get worn out the beds should be cleared, provided young stock has been raised to take their place. The ground should be trenched, and old lime and sand added where the soil is heavy. When the bed is well firmed the young plants should be set out. In a fairly open situation they should do splendidly.

Antirrhinums and Sweet Peas.—Boxes or pots containing seedlings of these plants should be set in cooler quarters to harden off.

FRUITS UNDER GLASS.

Melons.—It is not necessary to have a great depth of soil to grow first-class melons, but bottom heat I consider to be very essential. The bed should be made—if a pit is not available—on a bench situated a few inches above the hot-water pipes. Select good turves, 6ins. broad, and place these two deep, in lines 9ins. apart, along the front of the bench—*e.g.*, the glass front. Between these low turf walls spread a layer, 3ins. deep, of decayed manure; the remainder should be filled with a good compost in which fresh loam and old lime are included. The bed should be made very firm and left for several days to warm before the plants are set out.

Vines.—Continue with the pinching and training of the young growths in succession houses. Weevils often do much damage to the young shoots and leaves of the vines. A search should be made each night with a light around the woodwork and underneath the vine rods, and the weevils caught and killed; or spread something white on the floor and tap the rods to dislodge the weevils.

DAVID ARMSTRONG,
(Gardener to North More Nisbett, Esq.).
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Sparmannia africana.—This old greenhouse plant is worthy of more general cultivation, as plants continue to flower for several months during the winter. It is not generally known that the stamens of this plant are sensitive; if lightly touched they gradually spread outwards. This plant is easily propagated by means of cuttings at this time, rooting readily in a close case. They grow quickly and, grown on into six-inch pots, they make good plants for the stage in their first year, but they are seen at their best when grown into large specimens, either as bushes or standards. To ensure freedom of flowering the plants should be stood outdoors all summer in an open sunny position, taking them indoors about the middle of September.

Clivias are excellent plants for the conservatory, and, where they have been kept cool and somewhat dry at the root, a portion of the stock, if placed in a warm house in a temperature of about 55° they will soon come into flower; with sufficient stock, a succession of flower can thus be maintained over a considerable period. Clivias make fine large specimens if grown in large pots or tubs, and if so desired the plants may remain in the conservatory all the year round, as they make good, permanent furnishing. They also do very well if planted out in beds or borders in a cool house.

Aloysia citriodora (Lemon-scented Verbena).—On account of its beautifully scented leaves this plant is very popular for the cool greenhouse; old plants that have been kept dry all winter, should now be pruned hard back and placed in a warm greenhouse, where they will soon break into fresh growth. Many growers experience some difficulty in successfully propagating this plant, their failure is generally due to using too old shoots; when the young shoots are about three or four inches in length they should be secured as cuttings. At this stage they root readily in a close case, with slight bottom heat. To induce a bushy, well furnished habit, the young shoots should be pinched several times. If so desired this plant can be grown into large specimens.

Strelitzia Reginæ.—This handsome plant with its extraordinary looking flowers, can be grown in large tubs, but is seen at its best when planted out in a bed of good rich soil in a conservatory. Its large, handsome foliage is attractive at all times and it produces its flowers over a long period.

Cyperus alternifolius.—This graceful plant is very useful for grouping with other plants in all sorts of floral arrangements, not only in the greenhouse, but also for decoration in the dwelling house. For this purpose a succession of plants should be kept up, either by dividing the old plants, or by cutting off the whorls of leaves and inserting them as cuttings. They soon root in a warm case and quickly make good, useful plants. There is a beautiful variegated variety which is best propagated by division.

Lobelia Erinus, of which there are many varieties, apart from their value as summer bedding plants, are very useful for furnishing the fronts of stages in the conservatory; good varieties are propagated by means of cuttings; a few double varieties must, of course, be increased by means of cuttings. Excellent results can be obtained from seeds, as the varieties come nearly true; there are also several spreading varieties which are very useful for filling small, hanging baskets. Seed may be sown now in gentle heat. They should have quite cool treatment at all times.

THE BREAKING OF TULIPS

BY CHAS. W. NEEDHAM.

THE idea that the breaking of tulips is caused by the transmission of a mosaic disease which has recently been the subject of investigation and scientific research in relation to the potato, seems to require consideration. (The idea is no more acceptable to the Dutch than to the English grower.) If it be that the breaking of tulips is caused by disease, whether mosaic or some other virus disease, many curious features occur to one's mind, remembering experiences of the last thirty-five years: one's desire for "breaks" and one's anxiety to discover a perfect feathered or a noble flamed flower.

Our fathers in the cult, the florists of old, particularly of the first half of the nineteenth century, valued most highly a well marked bloom; these markings to be excellent had to be within limits that had been slowly evolved through years of experience, and up to standards that had been determined upon by those who raised and grew the English and Dutch tulip and best knew its capabilities and powers of development. These faithful inheritors of perhaps the oldest floral tradition, who knew and loved the flower, met together and exchanged their views, the experience of each being disseminated for the benefit of all—their object being the attainment of perfection in form, colour and marking. The standards were laid down here, in didactic terms, by George Glenny and Doctor Hardy, echoed by the general body of seedling raisers, and generally adopted by the growers of the flower, Dutch standards differing slightly. In these earlier years scores of thousands of tulip seedlings were raised, the results of efforts to obtain what seemed to the educated taste in tulip culture, flowers of the best type. Judged by the standards which then obtained in the floricultural world, a very fine tulip was a well marked one; whether it be a "grand feather" or a "majestic flame," perfect form it must have, with clear colour, and be quite pure. The ultimate aim of this esoteric cult was a broken tulip, or, as the floral law termed it, a rectified bloom.

To one brought up in the "nurture and admonition of the law," it is with somewhat of a shock one reads of a learned American plant pathologist alluding to "these mosaic varieties" when writing of broken tulips.

If the term "mosaic varieties" had referred to broken Darwins—Rembrandts—or broken Dutch, or broken Cottage tulips, or broken species of tulips, it would not seem to savour so much of sacrilege. Is there any scientific basis for believing breaking to be caused by mosaic or other disease? Recalling to mind all the efforts that were made to induce break: by depth of planting, liming, poverty of treatment, hard usage, change of soil and other methods that were in vogue to obtain the desired end—broken tulips—and then to think one need only have "conjured" a cloud of aphides from the near-by potato plants to produce the desired effect is rather startling! One cannot remember being entirely without numerous and prolonged visits from the "green fly": to plant in its growth, and to bulb in its resting stage—unwelcome on any occasion. If breaking be a result of a virus disease, transmitted by some particular kind of aphis, or other sucking insect, and spread by means of the juice of the plant, into which the poison was introduced by the visitor insect, in similar biological relation to the introduction of malaria in the human system by a carrier insect, then one or two problems at once appear for solution.

In a collection of English tulips, the result of thirty-five years growth and selection—after annual accretions and eliminations—are both breeders and broken varieties, the latter, of course, preponderating, since the tendency of the tulip is to break, and these tulips were bred to break. Many of the broken sorts once grew in the collection in the breeder stage, there are records, extending over twenty years, of the doings of the bulbs in the tulip book, each bulb and its progeny being identifiable in the bed, in the cabinet, and in the book, so that it is easy to trace the style of bloom of any particular bulb over the period named; some have broken, some have not! There are groups of breeder bulbs of one variety grown side by side, some have broken, some have continued to bloom as breeders. Breeders and broken ones, all are grown alike and subject to similar treatment. Why do some breeders still persist as breeders? Rose Hill, Annie McGregor, Mrs. Collier, Goldfinder, Sulphur, Talisman, Mrs. Barlow, all appeared in the breeder stage last year, and all have been in the same collection twenty years at least, it is true most of the older breeder types have broken, but some still remain.

In groups of seedlings raised fifteen years ago, and groups of seedlings more recently raised, both broken and breeder forms are seen. To say that some are touched by and some not affected by disease, does not seem a satisfactory answer. One has known weak-looking plants, that had been in the self or breeder stage the previous year, throw fine feathered blooms, and, lest one should generalise and think lack of vigour in duced the break, one had to note on the same bed, *per contra*, most vigorous examples of Dr. Hardy, Mabel and Annie McGregor, appearing in the flamed stage; all had broken from breeders of last year, weak and vigorous plants alike.

The mysteries of rectification are not easily solved, it seems to be part of the nature and functions of a tulip to exhibit at some time this changed appearance of the bloom. All coloured tulips that have colouring matter—anthocyanin pigment—on the inside of the outer skin of the petal, will break, or are liable to break; while true selfs, yellows and whites, that have not the aforenamed pigment, do not break.

Again, if broken tulips are touched or troubled with a disease, how is it that we have apparently very healthy plants—from a layman's point of view—still growing from sorts that broke fifty and seventy years ago?

Aglaia, San Jose and Heroine continue in the broken forms, their breeder forms having died out over fifty years ago.

In the course of fifty years many plants, that our grandfathers grew, tend to die out, it may be they die of old age, of obscure maladies, of unfavourable environment, or of wrong culture. On the other hand it may be that some virus disease attacks them and carries them off, and if so, sucking insects may be the carriers of such disease, as was outlined at the last meeting of the British Association.

Perhaps our tulips, in common with other plants, get disease—mosaic and other disease—but it has yet to be established scientifically that mosaic causes the breaking.

In earlier times than ours the broken form of the tulip bloom was the more esteemed; the self or breeder was valued for its inherent quality, for the possibility it possessed, of breaking in good style, and the change was eagerly looked forward to, extravagant expectations were often indulged in, and perhaps hopes were occasionally realised.

In any case the pleasure of expectation had been felt and hope springs perennial in the breast of the florist.

Since tulips were known and cultivated in Europe, 1550 or thereabouts, the breaking or transfiguration of colour has been the most fascinating feature in the life story of a single tulip entity.

Times change and we with the times. Our efforts are now mainly directed to the keeping of our tulips in the self or breeder stage admired by the many, and to the prevention of the break.

Once we know the cause of the breaking, it may be we are on the way to discover how to keep the self state, and perchance we may then be able to make some chosen varieties break, and to keep the majority of our tulips in the self colourings that appeal to the masses for their decorative value.

May we hope scientific research will come to our aid in these and kindred matters? Intelligent investigation would add to our knowledge and render possible the proper treatment of tulips and other bulbous plants which may in like manner be afflicted by disease.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Dropping of Lupin Buds (D. H. B.).—The usual cause of the dropping of lupin buds is either the attack upon their roots of a fungus or an insect, or may be at times drought or want of drainage interfering with proper root action. We know of no pest that actually eats off the buds in the way you describe. The V. T. H. slug traps are excellent for catching slugs.

THE NEW

Horticultural Hobby

Raising High Quality Gladioli from Seed.

HUNDREDS of garden lovers have already enjoyed the fruits of this new and fascinating pursuit, and Gladiolus growers the world over send to us for our pedigree seed. No seed of such quality has ever before been at the disposal of the public, nor has the ease and certainty of raising wonderful new types and colours in Gladioli ever been comprehended till our own results, during the last two years, were demonstrated by persistent showing in many parts of the country.

OUR NEW CATALOGUE shows a beautiful photograph of one of our many seedlings in flower, 7 months after sowing.

A Packet of 200 seeds from the best known Primulinus hybrids cost **3/6**, and it will prove the most interesting garden investment of the year for you.

Full cultural instructions with each packet.

TREES AND SHRUBS.

Clematis Withering (W. R. H.).—The dying back of the growths of clematises is a frequent source of disappointment with growers. It is usually attributed to one of the following causes: (1) The sun cracking the bark of the stems; (2) twisting and severely crippling the rather fragile stems; (3) most clematises are grafted and there may be damage at the point of union between stock and scion. From these suggestions it will be seen that it is largely a matter of care in the management of the plants.

Cytisus albus (A. S. S.).—It is probable that the plant is a seedling, and the other brooms may have been propagated by cuttings. As the plant is 5ft. high it should flower this spring. Seedlings, as a rule, grow vigorously at first instead of maturing flowering shoots, but you will reap the benefit later in having a large flowering bush. You do not state if the brooms are all growing together. Perhaps the white broom is in richer soil. This would account for vigorous growth instead of flower.

Name of Fruit.—(G. B. T. N.)—Apple Newton Wonder. One of the finest late cookers.

PLANT NAMES

IN the January issue of an American contemporary is an article, on Practical Plans for Planting Little Gardens, which consists of lists of suggested plants for various classes of small gardens. The nomenclature of these lists is interesting, as it consists either of the English translation of the botanical name or of a colloquial synonym.

Some of the colloquial names are obviously confined to America; whether the plants are grown in this country I do not know. I confess that double baby's-breath, orange sneezeweed, tickseed, gasplant and rosinweed are unknown to me, and what is more, they either convey no meaning or I conjure up an unfavourable impression of the plant. Double baby's-breath is quite unintelligible. I suffer from hay fever, and the name sneezeweed, however beautiful the plant may be, conveys to me the idea of masses of pollen blown about by the summer breeze with consequent sneezing. Tickseed, if the name is correct, means nothing else than a plant with seeds which stick to you like a burr, an unpleasant companion in a small garden. The name gasplant is distinctly reminiscent of the Brentford gas works.

No doubt I am maligning plants worthy of being grown in any garden, else, presumably, they would not be included in these lists, but one supposes that this article is written for the beginner in gardening, and as a beginner I should strongly object to having plants labelled with such names in my garden. Perhaps it is unfortunate that Latin and Greek are the common tongues of the horticultural world, but as it is an accomplished fact there is no other method but to use them. Per[illegible], what knowledge of plant nomenclature I possess gained through the use of the proper botanical name, and I jib at having to learn a second list of plant names.

The trouble is that in the English language words cannot be manufactured like they can in Latin or Greek; it is not sufficiently adaptable. Even the compiler of these lists has to admit this, for he gives the botanical name after several of the plants he mentions, as, for instance, evergreen azalea (amœnum) and Japanese mountain azalea (Kæmpferi). It is quite impossible to invent English names for the constant stream of new material coming into cultivation.

Another American habit is to give the literal translation of the botanical name. Why call Campanula carpatica—a popular plant the world over—the Carpathian harebell? It only makes plant nomenclature more difficult. A few other examples which I pick at random are Tartarian honeysuckle for Lonicera tartarica, a name by which it has been known since 1752; alternate-leaved dogwood, for Cornus alternifolia, a name given to it by Linnæus; Thunberg's spiræa for Spiræa Thunbergii. The English names are clumsy, and in addition, the important factor in a plant's name, the name of the genus, comes last, and so makes reference tedious and difficult.

In the British Isles this question of nomenclature is no such a difficulty. We take names as we find them and are satisfied with the botanical name of a plant. There is, however, a sentimental feeling, particularly among the older generation of gardeners, about keeping old-fashioned names. As a member of the younger generation, I boldly state that this is a mistake. It fogs the issue. The younger generation have never learnt these old-fashioned English synonyms, and when such names as yarrow or bitter-sweet are mentioned by their elders, they politely pretend to know all about them, not having the vaguest idea that they mean achillea or Solanum dulcamara.

Another difficulty is that many of these old English names are distinctly local and that what will stand in one part of the country is useless in another.

Most of the Latin or Greek terms are either an adaptation of the name of the finder or the country in which they are found, or they point out some definite attribute of the plant. It is surprising how quickly sufficient botanical Latin or Greek can be acquired to translate such a name into English. You may say, Why not use the translation to begin with?; but one of the advantages of these Latin or Greek terms is that they are definitely recognisable as names. Rhododendron porphyroblastum is long and tiresome. The translation is Rhododendron with purple buds. This at once loses all semblance of a name.

There are many pitfalls in the use of an English nomenclature. Among the commonest names are sinensis or japonica. The translation is easy: they mean Chinese or Japanese; but supposing the English translation was used—the Chinese or Japanese barberry, for instance. There are dozens of them which come from China or Japan. Berberis sinensis refers to one plant, but the Chinese barberry may refer to dozens. Let us steer clear of the American habit of using English names; it only complicates matters at a time when everything should tend towards simplification.

THE SPRING ROCK GARDEN

BY DR. R. LLOYD PRAEGER.

THIS IS THE GARDEN WHICH IS MOST EFFECTIVE IN THE SPRING, WHEN THE MAJORITY OF ITS INHABITANTS ARE IN FULL BLOOM.

I THINK that no kind of garden gives such joy in spring as the rock garden. This is largely because the majority of alpines and rock plants are spring bloomers, but more still on account of the endless variety of growth-form which the denizens of the rock garden can boast. The well stocked bulb garden is its most serious competitor and may be made a very delightful place, painted with blossom; but it cannot compare in varied charm with the rock garden, for the spring bulbs, belonging as they all do to a few allied natural orders, have a distinct family resemblance—erect annual growth, undivided, mostly narrow, leaves, and a certain sameness of habit. The population of the rock garden, on the other hand, drawn from nearly every race of hardy plants which is decorative or interesting, presents an endless variety of form and colour in stem, leaf and flower.

Although the latter part of winter sees many a fleeting gleam of colour in the rock garden, especially in mild districts, the spring display may be said to begin in March with the Kabschia saxifrages. Given reasonable luck in weather, these form groups which, for daintiness, are unsurpassed in the garden throughout its whole calendar. Whether we choose the safe but unambitious course of sticking to reliable plants like SS. apiculata, apiculata alba, sancta, marginata, etc., or venture on diapensioides, Boydii and lilacina, we will rejoice in having (or having had) them. Then there is that excellent early heath, Erica carnea, with its many colour-varieties, a host in itself. The earliest anemones, too, like the many-coloured A. blanda, are already in evidence. Adonis amurensis is also very early, with finely cut foliage and big soft yellow flowers; so is the little Hacquetia Epipactis, dwarf and golden. Many early bulbs, too—crocuses, snowdrops, grape-hyacinths of various kinds—brighten the March rock garden.

For April, a much more varied display is easily attainable, and a large number of dainty alpine herbs and bulbs are already peeping forth; but the main display of bloom is supplied by three genera—the "three A's" Arabis, Alyssum and Aubrietia—and, indeed, by one species of each: Arabis albida, with white flowers (single or double), a very common plant, but, none the less, invaluable; Alyssum saxatile, with golden or citron blossoms and greyish foliage; and Aubrietia deltoidea, giving tints which range from pale lilac to deep crimson and imperial purple. To these, of course, we must add the mossy saxifrages, with their plump, fresh green cushions and wealth of bloom: white, pink, and on to crimson. These four plants are such robust, reliable things, and between them give such a range of colour, that I often long to construct a rock garden on the grand scale, with great solid masses of stone, and stock it with sheets of these plants, ramping over the slopes and hanging in curtains down the rocks. The effect, especially as seen at a little distance—say, across a piece of water—would be brilliant in the extreme.

Then there are hepaticas from mountain woods—blue, red and white, double and single—and anemones of several kinds, among the loveliest being the pale blue varieties of our native A. nemorosa; and already the big woolly purple heads of A. Pulsatilla are pushing up from among the lacy foliage. Several species of corydalis, which already in March have displayed their tender fern-like foliage, are now in flower—C. cheilanthifolia, C. cava, and so on. Dwarf daphnes are filling the air with fragrance, and everywhere new life is springing forth.

When May comes, every day brings fresh flowers—achilleas, with silvery leaves and white blossoms; red, pink and white armerias with slender stems rising from plump green cushions; graceful aquilegias of every hue; pinks of a multitude of sorts, for the genus Dianthus is a host in itself, and unaided could furnish a rock garden. Then the erodiums and their cousins the geraniums are full of charm, with graceful leaves and delicately veined petals. The early irises are full of beauty and interest; rock roses are a sheet of colour of every tint but blue; there are graceful flaxes, some tall and slender, others prostrate; the dwarf poppies, such as Papaver alpinum, are in full glory; little white and red catchflies are gleaming; and blossoms belonging to fifty other genera go to swell the colour chorus.

AN INFORMAL ROCK GARDEN, WHERE PLANTS ARE ALLOWED TO SPREAD OF THEIR OWN FREE WILL. EVERY NOOK AND CRANNY IS FULL TO OVERFLOWING.

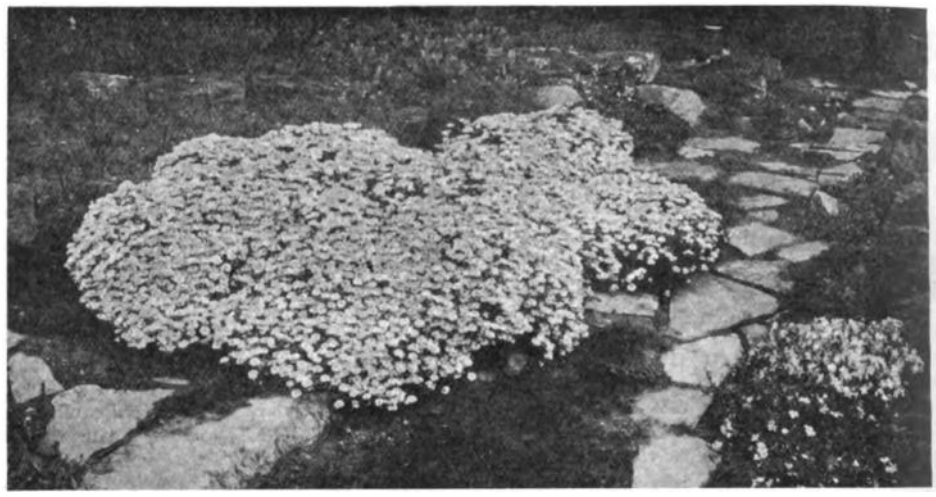
Especially in the south, the rock garden is best in May, because, along with the wealth of plants which in that month their "treasure on the garden throw," there is still the promise of much to come. Comparatively little is as yet in the seldom decorative stage of seed, while a profusion of species is still in the pleasantly anticipatory state of budding. These include many kinds of æthionema

Digitized by Google

with small grey leaves and slender spires of pink flowers; campanulas of fifty sorts (should we so desire), mostly blue—that most precious of colours; their cousins edrianthuses, also blue and very choice; erigerons of many kinds, like pink or purple daisies; gentians in variety, giving once more a blue note; yellow hypericums, many of which rank among the daintiest of shrubs; lithospermums—once more that precious blue. Biennials are unusual in the rock garden, for the true denizens of the rocks and mountains are almost all perennial, but an exception must be made in favour of meconopsis, which gives us a number of beautiful things with soft poppy leaves and spires of great delicate flowers of wonderful tints of blue and purple and yellow. Then there are primulas, too numerous to mention here; a great variety of veronicas, blue, purple or white; and, last but not least, those invaluable genera, sedum and sempervivum, which will flourish anywhere delighting in the driest places, and bearing a wealth of many-coloured bloom.

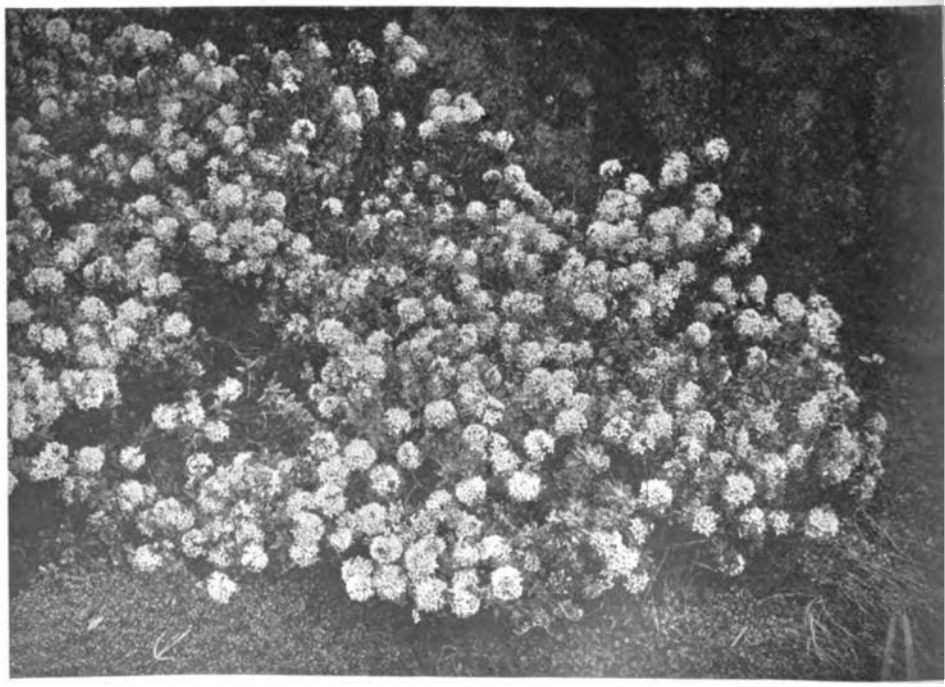
ONE OF THE FINEST OF THE EARLY FLOWERING WHITE SAXIFRAGES, S. MARGINATA.

Of late years a great deal has been said and written about this rock garden business, and it is legitimate to enquire how far rock gardening is to be regarded as a passing fashion, a "stunt" encouraged by the nurseryman, the writer about gardens, and the gardening papers (since it brings grist to all their mills); or how far, on the other hand, we are justified in thinking that it has come to stay, and will continue to occupy its present position as an essential member of the body corporate of English gardening. I feel no doubt that the latter is the case, and I base this opinion on the conviction that rock gardening has a definite æsthetic basis. Although until lately they were not extensively cultivated—partly on account of faulty knowledge of their requirements—the beauty and interest of alpines and rock plants have been long appreciated. And, indeed, among the endless forms of plant life which occupy our globe, what more charming than the fresh plump cushions of these little people of the hills? To the lover of beautiful things, the tiny flower-starred cushion of Androsace glacialis appeals as would a rose or a birch tree—two of the loveliest things in nature. To compare the alpines with the occupants of the herbaceous border is to compare jewels with furniture: to contrast the rock garden with the massed wallflowers and geraniums of the orthodox gardener is to contrast jewellery with wallpapers and carpets. Furniture and carpets may be both essential for the house beautiful, but there is room for jewellery also.



A FINE MAT OF IBERIS SEMPERVIRENS MAKING A CORNER PIECE BETWEEN TWO PATHS. THIS IS AN INDISPENSABLE PLANT IN THE ROCK GARDEN.

And not only the rock plants themselves, but their setting, if it is properly arranged, is pleasing to the eye. The grey or red rocks are a welcome change to the brown areas of soil, and the irregularity of outline to the straight lines or laid-out curves of other parts of the garden. The escape from formality which it affords is the most charming attribute of the rock garden, and it makes its appeal all the year round. But spring is rock garden time *par excellence*. Thus, in a sunny hollow, with alpine treasures of every hue bursting into bloom or glowing in full expansion, we may experience that soul-satisfying contentment that few but the gardener know; time stands still, the day's worries recede into insignificance, and even the luncheon bell may call in vain. May the rock garden long hold one of the premier places in English gardens!



PHNE CNEORUM, A VALUABLE SPRING SHRUB.

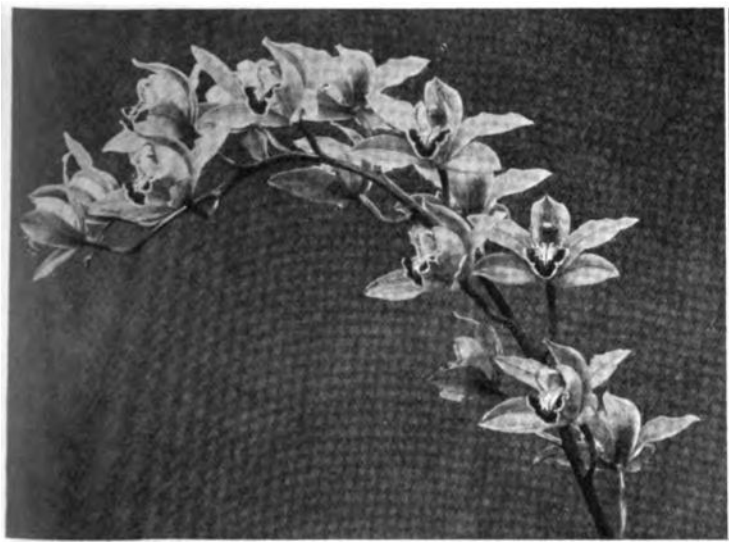
CYMBIDIUMS: ORCHIDS of EASY CULTIVATION

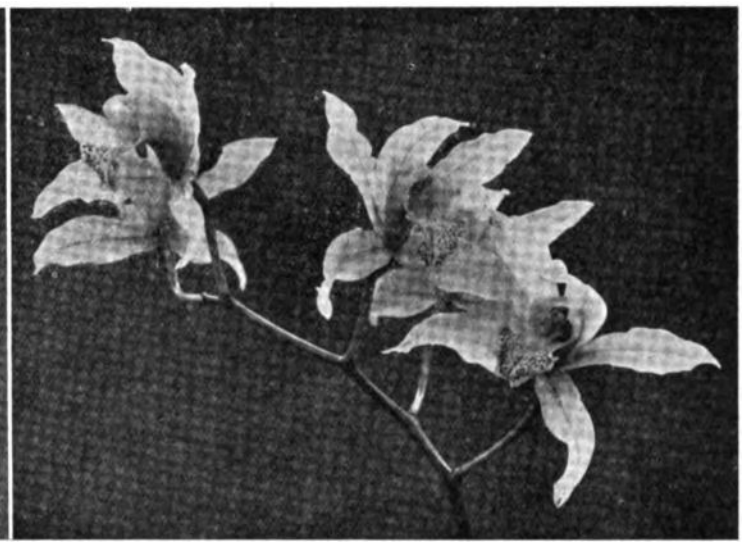
BY T. W. BRISCOE.

IT has been stated that every dog has his day, and this is certainly true in regard to various groups of orchids. Some ten or fifteen years ago the genus cymbidium was not held in very high esteem outside the gardens where a general collection of plants was grown, but to-day they are in the front rank and their popularity will increase rather than otherwise. The cause is not far to seek when we realise their decorative value, the ease with which they can be grown, the moderate temperature needed, and the low cost of many of the plants now in commerce. Among the older species will be found C. Lowianum, C. giganteum, C. eburneum, a beautiful ivory white, C. Tracyanum and C. insigne, all of which are worth growing.

The latter was discovered in Annan about twenty or so years ago, but it did not attract much attention until Messrs. Sanders of St. Albans exhibited plants under the name of C. Sanderi in 1905. It is a magnificent plant, producing flower spikes four to five feet in height, the flowers being white tinged with rose and the lip is more or less mauve heavily spotted with deep rose-purple. Such a distinct species was in great demand among orchid growers, the object being to use it for hybridising purposes, and the results obtained immediately placed the cymbidium in a most exalted position. Although the older species ought certainly to be represented by a few plants, it is among the hybrids that we shall find the material to form a collection, whether small or great, of these useful plants. The foliage of the cymbidium is long, arching and somewhat narrow, and a healthy specimen is always attractive even when not in flower. The spikes are more or less erect, but arch over gracefully towards the top. Hybrids vary in colour considerably, and out of a large batch of seedlings there will probably be one worthy of a distinctive name. These particular plants often realise high prices and are generally sold to a connoisseur, but the amateur or beginner will ignore these, and start with plants of average merit more reasonable in price. The following hybrids are well worth consideration, but the best plan is to see them in bloom, or consult a grower who specialises in these desirable plants. One of the first to be raised was C. Gottianum (C. insigne × C. eburneum), a plant worthy of wide cultivation. C. Alexanderi (C. insigne × C. Veitchii), C. Doris (C. insigne × C. Tracyanum), C. Pauwelsii (C. insigne × C. Lowianum), C. Schlegelii (C. insigne × C. Wiganianum), C. Sybil (C. eburneum × C. Pauwelsii), C. Corona (C. Lowianum × C. Schlegelii), and C. Castor (C. Woodhamsianum × C. insigne) are a few of the numerous fine hybrids there are to choose from to-day, brought about by the introduction of a single species, viz., C. insigne, and it is beyond doubt that this plant has revolutionised the genus if judged from the decorative or garden standpoint. Most of the hybrids are pleasing and attractive in colour, they have a stately and striking habit, and what is more from the beginner's point of view, they possess that desirable attribute, a robust constitution. Cymbidiums do not require a high temperature to bring them to perfection—a minimum of 50° being ample. Very low houses are not suitable for these orchids, but the average greenhouse will be found quite lofty enough, while a corridor at the end of a range of houses is ideal for them. They will also thrive among a miscellaneous collection of plants, providing a few cultural details are observed. A certain amount of light is necessary, and they need all the light possible the greater part of the year, but during the late spring and summer months moderate shade is essential. This ought not to be of a permanent nature, and should only be employed when the sun is bright. Ventilation is an important factor, and when the outside temperature is warm the top ventilators may be opened an inch or so providing it does not lower the inside temperature. Ventilators in the front wall of the structure are excellent for affording ventilation, the cold air then passes over the hot-water pipes before it comes in contact with the plants. Always avoid cold draughts, and consider the weather and direction of the wind before admitting air. The atmosphere is kept more or less moist by damping the floors and stages with water once or twice daily when the weather is hot, and a light spray overhead with tepid water will also be beneficial. Cymbidiums produce a quantity of thick, fleshy roots and therefore need moderate pot-room and a somewhat retentive rooting medium. All the ingredients are broken up into pieces about the size of a walnut, the fine particles of dust removed, and after adding a six-inch potful of crushed crocks to every bushel of the compost the whole is thoroughly mixed. Ordinary flower pots or deep pans are chosen and a thin layer of drainage material placed in each, over which is laid a little moss or loam fibre to prevent the drainage being choked with soil. It is important that the repotting be done at the right time, and few will go wrong if they watch for the new growth. This should be a few inches high, because at this stage fresh roots are made, and the plants soon re-establish themselves. Annual repotting is not needed, in fact, large examples will go for several years without disturbance, but young plants will need attention every two years. These are moved into larger receptacles without removing much of the soil, in the same manner as when repotting a pelargonium, but large examples will require dividing to keep them within reasonable limits. The roots are carefully unravelled and the back pseudo-bulbs are reduced to three behind each lead or growing point. If desired, each piece may be potted singly, but the best plan is to make up a compact specimen, distributing the leading shoots evenly over the surface and in such a way



CYMBIDIUM PAUWELSII.



A TYPICAL CYMBIDIUM HYBRID.

Digitized by Google

that the new growths will not reach the edge of the pot for a year or two.

When repotting, press the soil fairly firm, and leave it just below the rim of the pot or pan to allow space for watering. Some growers include a few live heads of sphagnum moss in the last layer of soil, but, apart from appearance this is not necessary. Newly potted plants must be afforded water in strict moderation, or the roots will decay, but once they take possession of the soil a copious supply is essential. The roots are kept moist at all times, the greatest quantity of water being needed during the period of activity, and rain water ought to be used whenever it is available.

Cleanliness is absolutely necessary, and when the growth is young a watch must be kept for thrips, these minute insects penetrate down the centre, and unless they are destroyed progress will be impeded.

Fumigation will destroy them, but the fumigant must not be employed too strong; it is better to vaporise the house two nights in succession rather than risk injury to the plants. Scale insects are occasionally seen on the pseudo-bulbs and old leaves, but these pests are easily removed with a wet sponge or a pointed stick.

With ordinary care and attention no difficulty will be experienced in growing cymbidiums.

FRUIT-GROWING IN SMALL GARDENS.—IV

BY RONALD G. HATTON, M.A.,
OF THE EAST MALLING RESEARCH STATION.

PRUNING IN SMALL GARDENS.

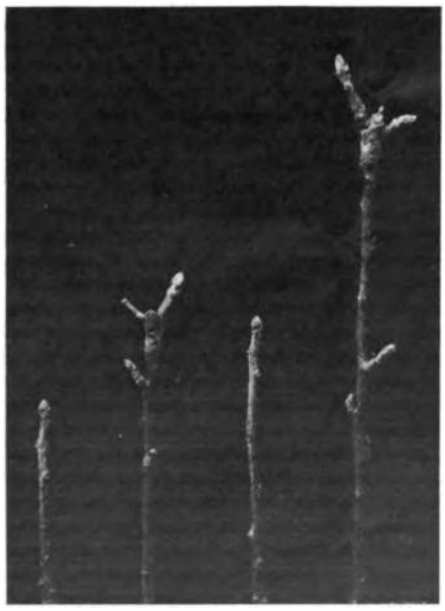
FIRST, with regard to pruning. Your trained tree has been chosen so that it may shade your small garden less, fringe your borders or cling to your walls. It has only a restricted space. There is an ultimate limit to its growth.

Now, at the outset it is worth repeating that the more you try to restrict your tree by hard winter cutting the more it will retaliate by wood-making in the coming season. Be gentle with your tree.

METHOD OF RESTRICTING GROWTH AND ENCOURAGING CROPPING.

Experiment has pointed out many ways by which we may coax it to modify its growth and produce fruit. First and foremost, there is the use of the root systems that restrict, then the more laborious method of root pruning or constant shifting. Try these methods first, for root restriction is desirable in the small garden. If your tree is not on the right roots, or if it does not respond to root treatment, you may resort to ringing or notching in the early spring. Science has verified and amplified what our ancestors long ago practised, and has shown that many an intractable apple may thus be made to fruit.

Experiment has proved and proved again that the less you prune, within reason, the more quickly your tree crops. True, your cordon and espalier must be pruned, but in so doing remember this main principle. And let me give you two others; the later you leave your pruning of main leading growths into the spring, the less violently will they retaliate; and again, pruning in summer of your side growths also tends to lessen the tree's vigour.



DESIRABLE FERTILE LATERALS TO BE LEFT.

PRUNING THE TRAINED TREE.

Your main object on the cordon, and therefore on the espalier or fan-trained tree, which is merely a multiple cordon, is to create a single straight stick upon which at every hand's-breadth is a fruit spur, bearing one or more perfect fruits, the whole under your complete control for picking, pruning, spraying. Within reason, the less you interfere with the main terminal growth the better until it passes right beyond your reach or the reach of a step-ladder.

Try to check first by bending it over, by ringing, by late spring cutting—but once your cordon is in heavy fruiting the cutting of the leader should not be much of a worry to you.

Now, as to the fruiting spurs, and lateral growths which you want to convert into fruiting spurs. You have two alternatives: to nip these latter back in summer or merely to "spur prune" in winter.

ALLINGTON PIPPIN'S NATURAL HABIT.

WINTER-PRUNING THE CORDON.

In commerce we rely almost entirely on spur-pruning in winter, and, so far, I find that trees on the little dwarfing stock Type IX fruit well on this method. It is quite simple. Let me take you through the stages by which we convert an infertile lateral wood growth into a fruit-bearing spur. Experiment has made sure these operations for the pruner. Mind you, some of your weaker lateral growths, on certain varieties, are best left alone for a few years, as they occasionally fruit on these "dards" and "brindilles," as the French call them. You can always work back these untidy little laterals later.

But after you have cut clean away at the base any very coarse laterals, as being too strong ever to be fruitful, turn your attention to the medium laterals and follow out this simple instruction.

First year.—Cut back your lateral to four or five good buds.

Second Year.—You will find, in most cases, new growth has been made at the point of cut, but that below you have something forming which looks suspiciously like a fruit bud. But do not be in a hurry, or you may find you force it into growth again. Cut back your new growth once again to within a bud or two of its base; then

Third Year.—You may cut right back to your fully established fruit bud.

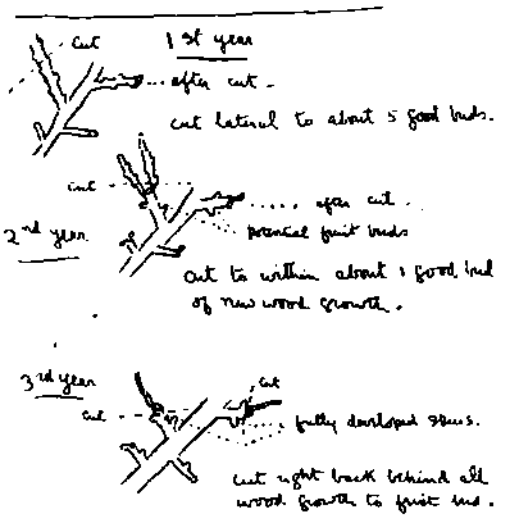
And now, remember that this fruit bud or spur is capable of infinite development. If you are careful in fruit picking it may rest dormant for the following year and fruit again the next, or it may form a short fruit-bearing dard. Leave such if there are not too many.

SUMMER PRUNING.

As an alternative you may summer prune your lateral growths. It seems possible that frequent lack of success in

Digitized by Google

this country, and consequent lack of faith in the method, are due to the fact that we are not sufficiently drastic. Commonly, we nip our laterals to four, five or six buds in July or August, or both, and then, if a season of late growth follows, we get nothing but new, short, unripened wood shoots instead of the hoped-for fruit bud. Experiment seems to be pointing to the fact that the harder you cut your laterals in summer the less likely they are to make wood growth again, and, therefore, the more likely to form fruit buds. If you have anything of the experimenter in your nature, try cutting back some of your laterals quite hard in summer, say to within one bud of the base, and watch results carefully under your conditions. To grow your wall plums and peaches you must, of course, resort to summer disbudding;



but remember that the peach and morello, especially, fruit almost entirely on last year's wood, but you can have too much of it. Success depends on summer nipping, and you had best remove all superfluous wood in this way.

THINNING OLD TREES.

If you are unfortunate enough to have large, old, shapeless trees in your garden, remember that they probably need light and air. Thin, cut out whole branches, work back side laterals until you can see the blue sky and work your arms comfortably within the spaces.

It is as well at the end to point out again that hard pruning is injurious to the cropping capacity of the tree. What should be aimed at is a *via media* when the best crops can be obtained without injury to the tree.

THE HERBACEOUS BORDER

BY H. W. CANNING WRIGHT.

FOR spring, as with autumn, planting of herbaceous plants, the most important point is thorough soil preparation. These plants will occupy the ground for three years or more, with only the opportunity to top-dress, so that deep digging and manuring are essential to success.

If the soil be light, use plenty of cow manure: if heavy, stable manure with plenty of straw in it, and *not* that where peat bedding is employed. A dressing of lime is always desirable; while kanit at the rate of 2 oz. per square yard, is a slow-acting substance that supplies potash. Let each and all of these be thoroughly incorporated into the soil, this being especially necessary in the case of the animal manures.

Freshly dug soil is not the best for planting, so that ten days or a fortnight should be allowed to elapse, after digging is completed, before the plants are put in. Meanwhile, leave the surface rough and rake down just prior to planting. This is beneficial in two ways: it aerates the soil and helps to dry it. The latter is very important, as perennials cannot be successfully planted in wet, clammy soil.

Spring is an ideal time for this, and the planting itself a very simple matter. We wish, however, that every grower would take as much care when dealing with his herbaceous perennials as he does when planting—say—roses. It is every bit as important to take out a sufficiently large hole and carefully spread the roots, covering in little by little with soil and firming as you proceed. Do not use the foot too violently, especially when dealing with such fragile-rooted plants as the alstrœmerias or the thong-like kniphofias. It is important that these should be made firm, but not by careless or violent means.

Spring planting also enables one to judge the depth at which the plants should be set: for, in a great majority of cases, growth will already have commenced, and thus one can see exactly how deep to bury. Fibrous-rooted plants—such as phlox or moisture-lovers that have their roots near the surface—benefit by a mulch of old manure, especially if the weather turns dry, and, in any case, quick re-establishment must be ensured by liberal waterings.

Turning now to varieties that can be especially commended for spring planting, do not overlook the aconitums—so valuable for retaining blue colour in the border late into the autumn; while the variety Wilsoni, in pale violet, which maintains a long season by means of its lateral growths, is splendid. Alstrœmeria, with its gorgeous blaze of orange-yellow lily-like blooms, will not flower the first year: but you are one year nearer the perfect plant by getting the roots in now, and there is no question that it is the safest period in the year to effect removal.

HERBACEOUS PHLOXES AMONG THE BRIGHTEST OF BORDER FLOWERS.

Hollyhocks will be grand in autumn, but use seedlings, and spray before midsummer if you would avoid disease. Japanese anemones may certainly be planted, while seedling antirrhinums should provide a blaze of colour. Asters are essential, and we do commend to your notice some of the many excellent giant-flowered novelties. Campanulas ought to be largely represented, for their long flowering season makes them indispensable. Do not hurry with outdoor chrysanthemums, but insert the labels and leave their spaces, lest you forget them.

Delphiniums are simply glorious back-row specimens, while some of those of dwarfer stature should also be allowed to break forward and carry their inimitable blueness towards

Digitized by Google

the front. The wonderful steely blue eryngiums should not be forgotten, and—here and there—a good bush of that ever useful plant, Gypsophila paniculata fl. pl. may find a place. Helianthus—tall, golden yellow sunflowers—and helenium, in a wonderful range of gold and coppery red, are both glorious for autumn display; while torch lilies—kniphofia—set the garden aflame from June onwards. Quite a feature may be made of these, and without risk of monotony, either in colour or form; while the period over which they bloom—May to mid-October—leaves nothing to be desired. I especially commend K. tricolor major, with strong upright stems, 3ft. tall. The expanded flowers are pale primrose yellow, the upper ones gold with a hint of green, and the unopened buds terra-cotta red.

K. comosa is very distinct, with short bottle-brush heads of brilliant carmine orange, 4ft. This species is unusual, in that it reverses the usual order by expanding its buds from the top downwards. K. erecta is good, the flowers coral-scarlet, unexpanded buds dull red. In this, when the buds are ready to expand, they point upwards against the stem; while the younger buds point downwards, giving a most curious effect where the two meet.

K. chrysantha is delightful with long spikes of golden yellow, the unopened buds being a lovely citron green. All of these should not be omitted from among the dwarfer plants, and worthy of special praise is A. acris punctatus, which does not exceed 1ft. in height. The leaves are deep green, with thin wire-like stems and light heliotrope flowers in great profusion.

In even the largest border it will be found that an immense number of dwarf and medium stature plants are required, for too many taller growers detract from that sense of breadth which is so essential to a good appearance. For its continuous flowering qualities, Helenium pumilum aurantiacum is difficult to beat and bears a great profusion of orange-yellow flowers through summer and autumn. For September flowering, Helenium autumnale cupreum—18ins.—is simply splendid, giving large bushes of bright coppery brown flowers which possess that luminous light that carries well across the garden.

If you want to combine value for cutting with decoration of the border, Coreopsis grandiflora Perry's variety, should please you. This forms neat bushes of foliage, from which rise enormous numbers of very large semi-double flowers of a vivid golden yellow. It is too late to plant sweet williams successfully, but a note should be made and seeds sown—for next year—of such vivid varieties as Pink Beauty. Meanwhile, such spots as they are to occupy may be planted up with violas,

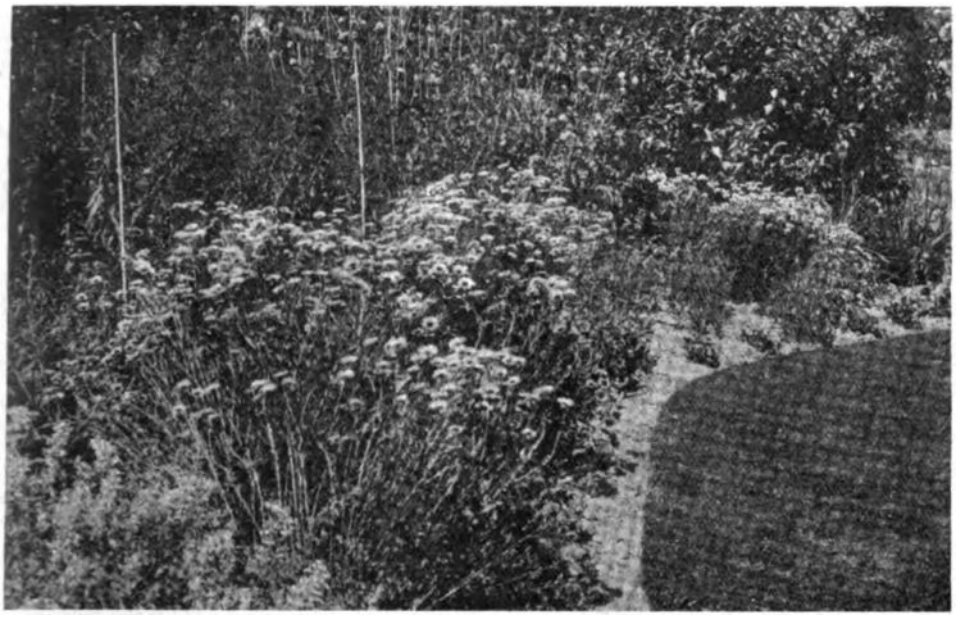
AN EARLY SUMMER BORDER BRIGHT WITH LUPINS IN MANY DELICATE SHADES OF COLOUR.

are, more or less, tall growers and suited to back row or middle positions; but full use towards the front should also be made of the dwarf forms. K. rufa, for example, is but 18ins. high, with thin wiry stems and golden yellow flowers lightly touched with coral red. K. brevifolia Macowani is similar in height, with small spikes of vivid yellow passing to tawny orange.

We always love the white everlasting pea—preferably at a corner, where it can shower its blooms about, somewhat untidily, in a natural bouquet that does not fade for weeks. It is not too late to plant the wonderful montbretias, while phloxes are a host in themselves, either in sun or shade. All peonies transplant well in spring; so do rudbeckias, and, in these, do not omit lacinata fl. pl. Some of the dwarf asters for these will give glorious colour masses until late into the summer. Heucheras are grand front-row plants and transplant splendidly now; while, if you have any old clumps, these will benefit by splitting into single crowns and replanting. See that they are kept moist, and they will soon grow again. Among these I can specially recommend H. brizoides gracillima, with branching panicles, 2ft. high, smothered with rich crimson flowers. H. sanguinea Pluie de feu, is a French introduction and a splendid plant, with fiery red flowers all through June and July.

No modern border would be complete without a generous representation of Allwoodii; these are excellent for meeting the demand for a dwarf plant that flowers over a long period in a variety of colours. Spring is the time *par excellence* for

Digitized by Google



THE END OF A SUNNY BORDER WITH A BACKGROUND OF TREES

not only freer flowering than the doubles, but are more brilliant in colouring and certainly better adapted for cutting.

If your border fronts upon a path, by all means seize upon the opportunity to edge it, here and there, with a few rocks. Not too many, nor too large, but just enough to give an excuse for massing broad sheets of some of the commoner rock plants, such as arabis, aubrietia, alyssum and certain of the more vigorous saxifrages. These give a glorious wealth of violet, purple, rose, white, gold and crimson, that will make your border fully as attractive in the early months of the year as it is in the summer. By thus massing your colour at the fore-front early in the year, you will find no lack of interest and, later, as these plants pass again to green, they form a neat and effective edging to the taller growers. In this connection the Megasea saxifrages are capital plants, and one can rely upon their handsome foliage throughout the year.

Finally, whatever you plant, do so generously: not fewer than three specimens to make a clump, and if the border is a large one, from a half to one dozen.

planting the splendid double and single pyrethrums. A special word of praise should be accorded to the singles, for these are

POTATOES FOR THE PRESENT SEASON

BY A. J. MACSELF.

ABOUT this time last year potatoes were a drug on the market. Growers were overloaded, and merchants could not deal with half the available supplies, despite ridiculously low prices. One result was that commercial growers decided to plant less, and a vast number of amateurs decided not to fill their limited space with a crop that could be bought at less than the cost of production.

The danger now is that scarcity and high prices of seed potatoes may induce many amateurs to plant their own instead of buying new seed, but that has, by experience, been proved to be false economy, as a complete change of soil and environment for potatoes is an essential to complete success. The extra initial cost is repaid fourfold in increased yield and quality. The potato is too important a crop to play with, and every owner of a vegetable plot should plant the best he can procure.

Of late years we have grown a large number of varieties. During the war greatest consideration was given to bulk of crops, and a certain number of varieties found favour which certainly was not due to merit beyond that of being heavy croppers. For the last two seasons, however, a marked change has been apparent, and there are unmistakable signs that considerably more attention is being paid to flavour, texture and form.

In this connection it is interesting to study the statistical information published by the Ministry of Agriculture in regard to the acreage devoted to the principal varieties in comparison with that of a few years back.

The particular list to which I refer concerns itself with potatoes grown mainly by the seed growers of Scotland, and as the stocks they grow are distributed far and wide the logical conclusion is that the rise and fall of a variety in seed-producing areas is an indication of its fate in private gardens, from whence the demand for seed arises.

The once sensational Northern Star was, five years ago, grown to the extent of 1,009 acres. In 1920 it dropped to 698 acres. By 1922 it had still further fallen to 443 acres, and in 1923 the figure was only 194 acres.

Commercial growers have evidently found that Northern Star failed utterly to fulfil the great things that were prophesied of it, and private growers must also have lost faith in it, for, depend upon it, if the demand for seed had been maintained the acreage would have correspondingly taken care of itself. For confirmation of this view we need only take the reverse case of Kerr's Pink, which in 1919 filled an acreage of 1,061. In 1920 it sprang to 4,451 acres, and in 1921 it took a further leap to 11,809. In 1922 it accounted for 11,326 acres, and in 1923 the figure was 10,988. Bearing in mind that the total acreage for all potatoes in 1923 fell far short of the average, Kerr's Pink must be considered to have held an extraordinarily good position. The reason for this is that it is a potato which combines capital flavour with heavy cropping capabilities, it keeps splendidly in storage and is immune from wart disease, which is an important point in scheduled areas.

A potato that I have many times eulogised and have urged many to grow is Tinwald Perfection. This, in 1919 occupied 682 acres. In 1922 it had risen to 5,125 acres. Last year it was down to 2,372 acres, but that, again, is probably due in part to the general decline in potato acreage, and it shows a striking contrast to Evergood, which stood at 3,273 acres in 1919 and was down to 320 in 1923.

Arran Chief has had a wonderful run of popularity. In 1919 no fewer than 32,477 acres were grown. Last year the figure was 21,021; but no other variety reached the twenty thousand mark, the nearest approach being King Edward with 16,899. The year previously it was 20,276.

Of varieties which have fallen most during the five years, Ally, Evergood, King George, Northern Star, President (from 5,142 acres down to 426 acres) and Templar may all be said to have been relegated to the category of failures, and they are all varieties that lack first-class quality.

Very striking is the progress of Golden Wonder, a potato that has no superior in flavour, but which for a while was saddled with a reputation of laziness in cropping power. In the year 1919, 3,767 acres were grown, and in each succeeding year the figures have increased as follows: 4,155, 5,305, 7,862, 12,403. What more eloquent testimony is required than this? and who shall still maintain that the Britisher is no judge of quality in a potato?

Both Sharpe's Express and Duke of York, two of the most serviceable earlies, have travelled from just over 600 acres each in 1919 to over 2,300 in 1923. The garden owner who does not quite know what to plant will be fairly safe in choosing a variety that is conspicuously on the upward grade, for commercial growers do not waste their acres.

NEW AND RARE CONIFERS

BY E. H. WILSON,
OF THE ARNOLD ARBORETUM.

PICEA WILSONII.

IN young plants of P. Wilsonii the branches are numerous, spreading, more or less upturned at their extremities, with dark green acute leaves, the upper inclined forward, the others spreading more or less in one plane at right angles to the shoot, from ½in. to ¾in. long, and lustrous on both surfaces. The shoots are slender, pale grey, glabrous or nearly so; the winterbuds are grey to dark brown, ovoid, non-resinous, with firmly imbricated, erose bud-scales. As it grows in the forests of central China this is a tree of moderate size, not exceeding 75ft. in height and 7ft. in girth of trunk, pyramidal in outline, with short, dense, horizontally spreading branches. It is fairly common on the higher ranges of north-western Hupeh at altitudes between 6,500ft. and 8,000ft., and appears to be even more plentiful in the province of Shansi, especially on Wutai-shan.

PICEA ASPERATA IN THE ARNOLD ARBORETUM.

It was discovered and introduced into cultivation in 1901 by myself, and a few plants were distributed by Messrs. Veitch. In 1909 William Purdom collected seeds of this spruce in Shansi, and the plants growing in the Arnold Arboretum were raised from his seeds.

PICEA ASPERATA.

In its juvenile stage, P. asperata is a sturdy-growing plant with relatively thick, spreading branches and dark green or glaucous leaves, stout, spreading on all sides of the shoot, very pungent and from ½in. to ¾in. long. The shoots are orange-brown, glabrous or puberulous; the winterbuds are nearly the same colour as the shoots, ovoid, swollen at the base, non-resinous, with bud-scales scarious and free at the apex. In a natural state this is a tree from 100ft. to 150ft. tall, with horizontally spreading, slightly decurving branches upturned at the ends, and old trees are very spire-like in appearance. The bark is grey-brown, fissured, and peels off in thin flakes of irregular shape; the cones, which vary from 3ins. to 5ins. in length, are fawn-grey. Some of the trees are very glaucous in appearance. This is the Chinese homologue of the Norway spruce, and is the common quadrangular-leafed species of north-western

FINE SPECIMENS OF PICEA ASPERATA, 80–110 FT. TALL, FORMING BELTS OF ALMOST PURE FOREST IN NORTH WESTERN SZECHUAN.

Digitized by Google

A NOBLE FIR, ABIES FARGESII, OVER 100 FT. HIGH.

PICEA WILSONII IN N.W. HUPEH 60–80 FT. TALL.

Szechuan, where extensive and almost pure forests of this tree occur. It was discovered in 1903 by myself, and in 1910 it was introduced into cultivation by seeds which I sent to the Arnold Arboretum. Its two varieties (notabilis and ponderosa), which differ in size of cone, shape of cone-scales and other minor characters, were also introduced at the same time, but as they grow in the Arnold Arboretum they are at present indistinguishable from the type.

A SEEDLING OF A. FARGESII IN CULTIVATION.

ABIES FARGESII.

When young, Abies Fargesii is a decidedly handsome fir, with lustrous, blackish green, ascending-spreading leaves, soft to the touch, each from ¾in. to 1½ins. long, and with two prominent white, stomatic lines on the under-surface and terra cotta brown, glabrous shoots. The branches are inclined upward, the winterbuds are ovoid, shining purple-brown and non-resinous, with firmly imbricated bud-scales. In China it is a noble tree, upwards of 100ft. tall, with a thick, columnar trunk and a narrow crown of short, massive branches, horizontally disposed. This is the common silver fir of north-western Hupeh and adjacent Szechuan, where remnants of old forests of it still occur. It was discovered between 1892 and 1898 by Père P. Farges, and introduced into cultivation in 1910 by means of small plants which I sent by mail to the Arnold Arboretum. The plants have proved perfectly hardy, and this fir promises to be a very important acquisition to gardens.

THE TRIFLORUM SERIES OF RHODODENDRONS

BY E. H. M. COX.

THE article under this rather frigid title will, I hope, help to popularise a series of rhododendrons which without a doubt are among the most useful, accommodating, and beautiful of flowering shrubs. Rhododendron species, as a rule, are looked upon by the amateur with rather an unnecessary awe. It is true that many of the newer species are hardly in general cultivation as yet and that well grown plants of almost all of them, whether new or old, are on the expensive side. I hope, however, in this and a further article or two to prove that some rhododendron species are worth growing by anyone who has a garden.

So numerous are rhododendron species that to help in their identification they have been serialised; that is to say, species which have certain well defined characteristics in common are grouped together around one plant, usually the first of the series to be discovered. In this case the type member is R. triflorum, a Himalayan plant found and introduced by Sir Joseph Hooker in the fifties of the last century. It is, perhaps, unfortunate in this case that R. triflorum was the first of its series to be discovered, as it is about its least worthy member and is now rarely met with in cultivation. It is fairly hardy, but its colour is a greeny yellow of no distinction, and it can be dismissed with no further description.

The main points in favour of the Triflorum series are that they are quick growers, easy to cultivate, amenable to many conditions found in British gardens, easy to strike from cuttings, with a few exceptions absolutely hardy, and without exception very floriferous. They are all twiggy shrubs from 4ft. to 10ft. in height; the leaves are narrow and tapering at both ends; the flowers are carried in loose terminal clusters; the corollas are almost flat in appearance owing to the diameter, which is large in comparison to the length of the tube.

The facts to remember for their successful cultivation are as follows: Absence of lime in the soil is essential; a soil which allows for good drainage is necessary; they should be planted where they can have shade in moderation; shelter from wind is advisable; they require a certain amount of moisture; there should be a quantity of humus, either leaf-mould or peat, in the soil—if it is not present it can be added; to propagate from cuttings, half-ripened wood should be taken.

Their beauty is not of that bold character so often associated with rhododendrons. They have no large fat trusses which sit up aloft and stare at you. Their beauty is far more elusive and is not to be found in the examination of a single flower—or even of a single plant, beautiful though that may be. Theirs is a beauty gained from a mass which shimmers like the folds of old silk. Whatever the colours are they are delicate in shade. That being the case, it is advisable, where possible, to plant them in groups of one species. In planting seedlings allowance will have to be made for their quick growth. As a general rule 4ft. is a good average to keep between them.

THE MOST FREE FLOWERING OF THE SERIES, R. YUNNANENSE

RHODODENDRON OREOTREPHES, ROSE FLOWERS TINGED WITH LAVENDER.

The best members of the series are the following:

R. AMBIGUUM.—This plant comes from Hupeh in China, and has yellow flowers with a faint greenish tinge to them. This tinge is no deterrent, for it is clear in tone. R. ambiguum flowers in late April and early May. It is particularly useful in our gardens, as it will stand hard usage and is very accommodating as to position. It should not be planted close to orange and yellows, which do not show off R. ambiguum to advantage.

R. AUGUSTINII, called after Professor Augustine Henry, by whom it was found in Yunnan. The colour is rather variable, and care should be taken as to its selection. Its best form is one of the bluest rhododendrons in cultivation; it was introduced by Wilson under number W.4238. The colour ranges from this bluest of lilac colours to a muddy pink-lilac, which should be avoided. It flowers at the same time as R. ambiguum, but asks for rather more attention as regards situation. It should be planted in light shade, and to get the best effect should be kept fairly moist.

R. CHARTOPHYLLUM PRÆCOX.—My especial favourite in the series. The leaves are rather

Digitized by Google

broader and the plant is more bushy than the usual members of the series; it is also semi-deciduous. The flowers are white or the very palest pink in colour, usually with crimson markings; in one form the markings are orange. They are both equally attractive. Its appearance is so diaphanous in full bloom and its habit so graceful that it may well be grown as a specimen plant. That I am not the only admirer of this plant is shown by the fact that in North-West Yunnan it is the only rhododendron cultivated by the Chinese in their gardens. This is praise indeed.

R. LUTESCENS, with pale yellow flowers. Not quite so hardy as the rest of the series, for it flowers early and is sometimes cut. It requires a certain amount of shade and shelter. To appreciate its pale beauty it should certainly be grown in a clump.

R. OREOTREPHES.—One of the best. It is farthest away from the typical triflorum, for the leaves are more oval and have a bluish tinge to them. The habit is more bushy. The flowers are deep rose with a trace of lavender. It is not particularly touchy about moisture and will flourish on a moderately dry bank.

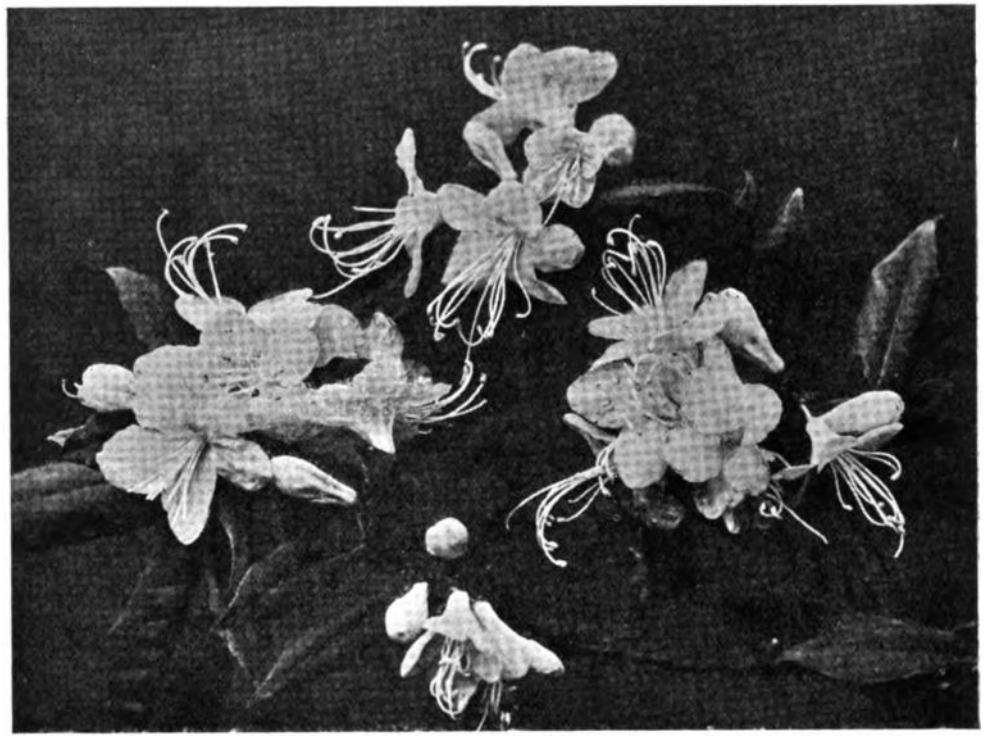
R. VILLOSUM.—A purple beauty. Messrs. Gill of Falmouth showed a particularly fine form of it at the Chelsea Show of 1923. Its colour was deep and so rich as to be almost a royal purple.

R. YANTHINUM.—One of the most variable in colour, ranging from nearly pure white to purple with brown blotches. Like so many rhododendrons of variable colour, it can be very fine or it can be horrid. It is worth while picking out a good form and striking your own cuttings in preference to growing from seed, as the seed does not come true to colour.

R. YUNNANENSE.—One of the greatest favourites and perhaps the most floriferous of a floriferous series. The colour is pale pink with crimson spots or blotches. This is a very common plant in China and is really magnificent. At the Royal Botanic Gardens at Edinburgh they have a hedge of this rhododendron which is worth travelling from the ends of the earth to see in full bloom in early May. It is absolutely hardy and accommodating.

R. ZALEUCUM.—The largest member of the series. It will grow to a bush of 14ft. or more in height. The colour varies from a pale lilac to a blue-lilac, almost approaching the finest form of R. Augustinii in tone. It is quite hardy, but not quite so floriferous as the rest of the series.

This by no means finishes the list, but I hope that there is a sufficient selection in the above to tempt people to grow these fascinating plants. Without a doubt it is the series of rhododendrons best suited for the ordinary garden. All the plants mentioned are in general cultivation, and can be obtained from many nurserymen who specialise in rhododendrons and shrubs generally.



PALE YELLOW, R. LUTESCENS. TO APPRECIATE ITS BEAUTY IT SHOULD BE GROWN IN A CLUMP.

TULIP TALK

BY THE REV. JOSEPH JACOB.

THE TULIP IN LITERATURE—ARM-CHAIR GARDENING—THE LAUGHING CAVALIER SCENT—JOHN REA—THE CAUSE OF THE MANIA—WHAT GREAT LADIES WORE ABOUT A.D. 1635—TYPICAL EXAMPLES OF SUCH FLOWERS.

IT is just what happens when one has decided to build a house. Up to that time one passes by houses or goes in and out of them with, comparatively speaking, unobservant eyes. But once the fateful decision has been made, it is surprising how one notices matters one never noticed before. It is the same in the world of flowers. Once the Rubicon has been crossed and a "Curious" has said to himself, "I am really going in for this or that," it is wonderful how he takes note of this or that whenever he comes across them in his ordinary reading. Only the older generations of gardeners will remember dear old F. W. Burbidge. He was "great." I remember a long talk we had about what I may call armchair gardening. His idea was that long winter evenings might be utilised in trying to get together a collection of references to a special flower, or to special flowers, in literature. I did not know it at the time, but he must have done something of the kind with regard to the daffodil, as I can prove from some papers of his that came into my hands after his death. The seed Burbidge sowed has germinated. What he did with the daffodil, I now find myself continuously doing in the case of the tulip. Now, luckily for me, the tulip is, perhaps, the best of all flowers for armchair work. Very likely Mr. Arthur Grove could produce lily references galore, and Mrs. Darlington rose quotations as sand on the seashore; but, considering that the tulip is, as it were, a flower born out of due time, with hardly four centuries of civilised existence to its credit, it is a standing wonder how frequently references to it are to be found in just-bread-and-butter writings. It seems as if the pleasant shock of its sudden appearance in the sixteenth century still reverberates, and that we need no super-powerful receivers to hear the famous broadcasting of the Mania time of 1635–37. Truly, as a Western flower the tulip had a great send-off. One of my latest finds is in the Baroness Orczy's "Laughing Cavalier" (now no longer to be found on Frans Hals' splendid canvas or under the pen-name of "Diogenes" in the Baroness' book, but, if I mistake not, in something very like flesh and blood at the Council table of the mighty in Vincent Square!). The rivalry of the rich men of Haarlem, and the handiness of the name of Mynheer Beresteyn's "Schwarzer Kato," are more or less the sort of references that one expects. What "found" me most of all was the description of the heroine Gilda's "small white hand" as possessing "the subtle fragrance of tulips." Well done, Baroness! You have said what is very true. Putting on one side the stronger scents of Sulphur, Jenny and Prince of Austria, nearly all garden varieties have a strange undefinable aroma which fascinates and allures like that well known smell of the East. Here the armchair gardener might register a vow to try his spirits—that is, his tulips—and let his poor old nose have a

Digitized by Google

chance. It likes having something to do, although some modern raisers of flowers seem to forget this. Suppose all roses were Frau Karl Druschkis in their scentlessness and other families followed suit—the next step would be atrophied noses!

Again, another value of this reference collecting habit is the historical one. Gardening is a great asset to the eye, the nose, the tongue and, in more ways than one, to the mind. The first purely gardening flower book that was produced in England was John Rea's "Flora, Ceres and Pomona," which appeared in 1665. It has been far too much overshadowed by the larger work—the "Paradisus"—of Parkinson; but if I wanted to know what *actually* was grown in the best English gardens about this time, I would go to the work of Rea and not that of Parkinson. In one of his dedication poems—that to Lady Gerrard of Gerrards Bromley—we get these four lines:

"Mark how the glorious Tulips rise
In various dress, to take your Eyes,
And how the fair'st and all the rest
Strive, which shall triumph on your Brest."

I call attention to them not because Rea considered tulips "the most glorious ornaments of the best Gardens" or in order to discuss the differences between "the early, middle, and later flowering varieties" of which full lists are given; but because he tells us that they were worn on ladies' dresses. This, of course, naturally calls to mind the Mania time. As far as I can learn, the initial cause of the incomprehensible madness of the people of the States of Holland was the simple and natural one of the rich young men of Paris to procure for their best young women the finest and the rarest of flowers for them to wear in their dresses in an evening. Just as I seem to remember in my early days camelias in the hair were all the rage. "In her hair she wore a white camelia," so "Tulips in her dress" would portray the floral embellishments of the seventeenth century belle of the ball. Can I give any idea of the type of tulip that might have been worn in those distant days? Yes, I think I can. They would almost to a certainty be striped ones, or edgers, that is, with an edging of a different colour from the body of the petal as we now have in the "Lac" type. Their petals would be more or less pointed. Their colours would be much as we have them now, only the greater the mix-up the more they would be esteemed—"Agot" and "Morillion" were two of the names given to what we would now call "strains," and denoted different mixtures. If a striped were used it might be something like Admiral Reyniers, Globe de Rigaut or Golden Bride of Haarlem. If an "edger," it would very likely feature Mrs. Elwes, Lac van Rhijn or Duchess of Parma.

Some of these may be in flower now, or may have just passed out of flower and be remembered. They are generally, nowadays, grown under glass. Those who force tulips might like to jot down the names, so that another season they may be able to say to friends as they go round the greenhouses or see them in their sitting-rooms, "These are the sort of things that Mynheer Beresteyn and his friends bragged about, or that Lady Gerrard wore if ever she gave a ball in spring-time at Gerrards Bromley."

A PICTURESQUE AND DELIGHTFUL FIELD OF TULIPS

THE BIG BUD MITE WHICH IS DECIMATING THE BLACK CURRANTS

BY SIR GEORGE WATT.

THE alarming disease met with on black currants and known as the big bud or gall mite was first recognised in this country about the year 1850. It was then recorded from one or two localities, but viewed more as an entomological curiosity than as a dangerous pest. Since then it has spread over the length and breadth of the country and become so serious that it may be said to threaten the very existence of black currant cultivation.

DESCRIPTION.—According to entomologists, it is not an insect but a four-legged acarina or spider. It is about one-hundredth part of an inch in length, so that it cannot be seen by the naked eye, though readily discovered on cutting open a swollen bud lengthwise and examining the central axis of crowded young racemes of flowers and distorted embracing bud scales, using for that purpose the magnification of a ten or twenty power lens.

PROTECTED AND EXPOSED PERIODS.—Once the mites make their escape from the buds and get on to the leaf-stalks, twigs, etc., they drop from twig to twig or to the ground and, I believe, are wafted on the breezes far and near. Crawling about all over the plant, they have little difficulty in getting attached to insects, birds, or the dresses of people working in the plantation, hence, by numerous different methods, they doubtless are carried to new feeding grounds.

During their residence within the buds the mites are completely protected from both their natural enemies and the chemical reagents used for their destruction. The period of exposure is, however, very short, for no sooner does the mite reach a new bud than it at once crawls between the bases of the imbricating scales and soon finds itself in the very heart of the bud—a veritable city of refuge—where its descendants may reside in perfect safety for some time (six to nine months) before their depredations cause the bud to swell and burst open and the resulting scarcity of food renders migration imperative.

DIFFICULTIES OF TREATMENT.—It is the brevity and intermissive character of the periods of exposure and the complete security at once attained within the bud, that render all methods and materials of chemical treatment next to futile. Insecticides are of value only when the mites are wandering about outside the buds, and if they all were to come out at one and the same time they might be dealt with effectually. An insecticide may be used with good effect to-day, but a few days later a fresh swarm may occur; hence to be really effectual the insecticide would have to be used every now and again throughout the year. It is the failure to recognise repeated swarmings that has led to so many false hopes of success. There is, of course, one great swarming season, namely, from March to May; but there are, in addition, what may be called individual bud swarmings throughout the year, except during the coldest days of winter and spring.

From May to July the mites may be said to disappear—there are many fewer swollen buds present then than at any other time. The mites from the great swarming season have either found their way into new buds or have perished. Buds in every stage of mite infestation may be discovered, however, on one and the same shoot: some large, greatly swollen, widely open at the apex, and with mites clearly crawling out of them; others sufficiently advanced that they

Digitized by Google

will open in a week or two; still others only partially swollen or not swollen at all and with the apex securely and firmly closed, nevertheless mite-infested. The last-mentioned have quite recently been invaded, and just now there may be within only one mite or a very small colony so that they may be difficult to discover. These facts explain why the systematic and even persistent removal of all big buds, as also the removal of all visibly affected portions of bushes, are of necessity futile methods of treatment. The buds left on the bushes, though they may not be big buds, may still be mite-infested and very shortly will swell and discharge their hordes of mites ready to attack the buds of the new shoots. And buds of new shoots are more readily attacked than buds on old shoots, so that the pruning has only intensified the malady.

SUGGESTION OF FIRING AS A REMEDIAL MEASURE.—In 1922 I was asked by the Directors of the Crichton Royal Institution of Dumfries to take the supervision of a fairly large plot of badly mite-infested black currants (1,932 sq. yds., or 427 plants of Boskoop Giant). I was given authority to conduct any experiments that I believed might lead to the discovery of practical results. I may explain that for some years previously all known methods of chemical treatment had been tried, but with no beneficial results. Heavy pruning had also been resorted to, but shortly after there was not a bud free from mite on the young shoots that sprang from the collar-pruned stools. Clearly, something more drastic had become necessary, or the cultivation would simply have to be abandoned and land somewhere else found for a new plot.

Experience gained in India suggested to my mind the possibility of success by burning the bushes to the ground. I satisfied myself that suckers were so freely and readily given off by the black currant that, were the plants burned *in situ*, fresh shoots almost for certain would be given off from the underground stems, and the plants thus resuscitated very possibly might prove to be mite-free.

I have reason to suspect that there may be a hibernating stage in the life-history of the mite, and that it then rests in the soil. If, therefore, firing be sufficiently well performed, not only would every trace of mite-infested buds be destroyed, but the soil also would be purged.

Having arrived at the conclusion that a systematic firing as a remedial measure should be tried, certain practical issues had next to be dealt with, such as the following:

SEASON OF FRUITING.—I realised that it was more important to consider the plant than the mite. Firing would, therefore, perhaps, best be accomplished in February-March-April, or just before the sap begins to ascend or the plant to sprout. The actual date selected would, no doubt, vary slightly, according to locality; the idea being that the burned stools would thus have not more than a few weeks delay before the ascending sap forced them to sprout. With a longer interval between burning and the ascent of the sap, there would be danger of the weakened plants not surviving.

METHOD TO BE PURSUED.—The work should be proceeded with in strips of, say, 6ft. to 8ft. in breadth, right across (and 3ft. beyond) the brake. The bushes (within that strip) should be cut down to within 3ins. of the ground and placed temporarily behind the operator. The surface of the strip should next be given a thorough hoeing to a depth of 2ins. or 3ins., sufficient to open it up completely. The strip should then be carefully covered by a layer 6ins. deep of old dry straw, paper, etc., and over the top of that should be laid the prunings of the currant bushes. On this, again, should be spread a second layer of straw or other readily combustible materials and on the top of that thrown dry hedge prunings, spruce thinnings or anything available that will burn. On no consideration should the strip be trodden on after being hoed, as it is desired that both the currant prunings and the soil should be burned sufficiently to kill all the mites that may be on or within them.

After the first strip has been prepared, a second should be taken in hand, then a third, and so on till the entire brake of currants has been converted into a pyre of 18ins. to 24ins. in depth, ready to be fired. It should be ignited on the windward side, choosing a suitable dry day, not too windy, as it is preferred to secure slow, steady conflagration, not a sudden blaze.

SUBSEQUENT TREATMENT.—The charred twigs should be removed and the surface soil dressed. The ashes should be pushed aside and fresh soil drawn towards the stools. All the ashes should be carefully forked into the soil, not left to be blown away. If the burning has been done in March, a month later the plants should be sprouting freely. The death rate will be found to be between 8 per cent. and 20 per cent. The losses depend entirely on the extent of the previous ravages of the mite. The root supply of the resuscitated plants will be found far in excess of the stem requirements, hence a superabundance of shoots, many of these faciated, will most probably occur, so that pruning or thinning may become necessary.

RESULTS.—The Crichton experiment, alluded to above, was performed on March 22nd, 1922, when the entire brake was fired, but to make sure, next day it was again fired. On April 30th the plants had commenced to sprout freely, and on July 18th it was reported that the treatment had cost £13 13s. 6d., and that out of the 427 plants 91.1 per cent. had completely recovered. Firing had thus proved a practical measure so far as the recovery of the plants was concerned, and the mite, up to that date, had not reappeared. But on March 25th, 1923, a year later, I examined the entire brake once more, plant by plant, and ultimately found one bush with a few small rounded purple-coloured buds, right down near the ground. These were found to contain a few live mites, feeding in the very position (within the bud) that the mite, aft-

SECTION THROUGH A BIG BUD SHOWING MITES WITHIN. *Greatly enlarged.*

ERIOPHYES RIBIS *Highly magnified.*

Digitized by Google

the great swarming season, usually succeeds in attaining about June-July: the buds had only just been invaded. I at once directed that that bush and the few adjacent ones should again be fired. This was done, and by June every one of them had once more sprouted and their shoots were a foot high. They did not appear to have suffered in the least, so that as a practical measure it may be found necessary to correct imperfect firing by refiring until the mite is entirely eradicated.

CONCLUSION.—To-day, the Crichton plot of black currants is growing vigorously, the plants are over 3ft. in height and laden with flower-buds that give promise of a full crop, while the mite is nowhere to be seen. So far as I can judge, therefore, the treatment would seem to be a complete success. Should contamination from external sources occur later on prompt refiring of isolated bushes as seen to be contaminated should prove an infinitely less expensive treatment than any of the methods of control known to me. I shall continue to watch the progress of the Crichton plot—my first adventure in the fire-treatment—and at some future date may report success.

NOTES FROM CONTRIBUTORS

A WARDIAN CASE.

THE accompanying illustration shows a Wardian case packed with young rubber plants for export. This is, without doubt, the best method of sending growing plants on long journeys. It is best described as a miniature greenhouse with half the roof removable. The roof is of frosted glass protected by slats. The bottom is filled with fibre and the plants are planted in it and rammed down as hard as possible to keep them from shifting. Between each row of plants a batten is nailed down on top of the fibre; it is thus impossible for anything to shift during transport. The side is then screwed on and the plants are ready for their journey, and will remain quite happy without further attention for a considerable time; but attention can be given by removing the side if necessary. Ventilation is supplied by two holes at the top; these are covered with wire gauze and inside them are little boxes (open at the top) which prevent any salt spray entering and doing damage. It is to the introduction of rubber plants by this method that the Malay States owe their present great industry.—L. B.

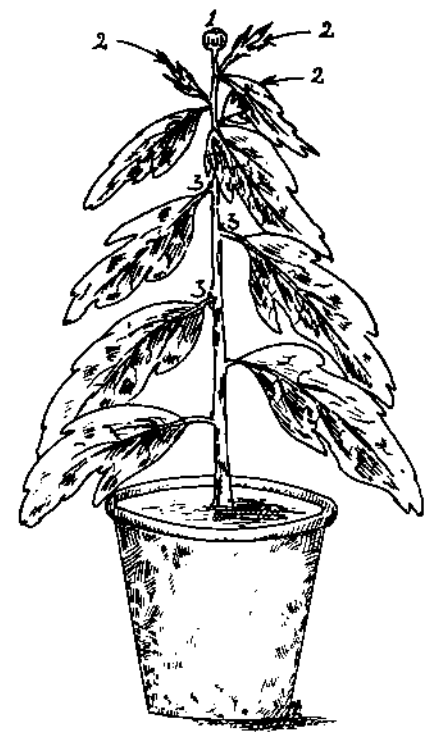
A MINIATURE GREENHOUSE FOR TRANSPORT PURPOSES.

POTTING AND STOPPING CHRYSANTHEMUMS.

THROUGHOUT March and April these plants will need repotting into 5in. and 6½in. pots if raised from cuttings inserted last autumn—November—and early in January. Those rooted first will be in good condition for placing in the 6½in. pots and the later ones in the 5in. pots. These remarks do not refer to cuttings quite recently struck but to forward stock intended for the production of exhibition blooms and specimen plants for furnishing greenhouses and conservatories. It is at this stage of growth that some varieties show the first crown, but which is termed the first "break." If the naturally early sorts, such, for instance, as Viscountess Chinda, show buds, the latter should be removed and new side shoots taken on, which will, in due course, show another bud—in May, probably—and these second breaks will cause more side shoots to form on which in August the desirable bloom buds will appear. Briefly, this is the treatment for early-flowering varieties that are required for exhibition late in October and early in November. The naturally late-flowering sorts, of which Mrs. Gilbert Drabble may be mentioned, require slightly different treatment. The formation of the first bud will, on a healthy plant, be delayed till, perhaps, a date too late to allow of the desired early crown bud being secured, so the cultivator should remove the tips of the main stems of these late-flowering plants early in April. In the accompanying sketch No. 1 shows the bud; Nos. 2, 2, 2, the three desirable side shoots to retain; and Nos. 3, 3, 3, denote where lower shoots must be removed altogether. Those side shoots, Nos. 2, 2, 2, if growing on a late variety, will be the ones to retain throughout the summer till August, when the crown bud forms on them. Plants of varieties to form specimens should be stopped a second time, in May, when the shoots will be increased to nine or a dozen, the flowering time being in November. The repotting should be carefully done at this stage, and finally. Use a good compost: fibrous loam two parts, rotted leaf-soil one part, old mortar rubble and rotted manure in equal proportions one part. To each bushel of the combined parts add a 5in. potful of bone-meal. Use clean pots and crocks and make the soil moderately firm.—GEO. GARNER.

CONCERNING SALVIA PATENS.

TO lovers of this rich blue-flowered border plant the following brief note attaching to its propagation may prove of interest. I have just recently potted off some autumn-rooted cuttings and some autumn-sown seedlings, both of which were put in last September. The cuttings are by far the stronger plants and bigger, especially as regards the tubers formed, it being necessary to use 3½in. pots to accommodate them, and this size was none too comfortable for a few of the best plants. On the other hand, all the seedlings, with one exception, would go into 2½in. pots, many of them into 2in. pots. The exception plant was the first seedling to come up—hence its better size—but even this could not reach the size of the cutting examples. I have never before experimented with seed of this sage, some of which was rather long in germinating. The seed was fresh gathered and sown in a slightly heated greenhouse. It remains to be seen whether there will be any ultimate difference between the two batches of plants; but perhaps nothing more than a little variation in the depth of colour of the flowers of the seedlings will be noticeable. It is sometimes recommended (I saw it lately somewhere) that early in the year is a good time to put old roots of Salvia patens into heat with a view to producing rooted cuttings for this year's use. This is perhaps the case, and from such practice no doubt quite passable plants are obtained. There can be no question, however, as to whether autumn is the better season in which to root cuttings of this plant, for these have a start over the spring-rooted plants of at least four months in which to be enlarging or forming the tuberous root-stock, without which vigorous bushy specimens of plants are not possible. Obviously, too, spring-sown seedlings stand but a poor chance of strong development and effective blooming during the same year, whereas, sown at the end of the preceding summer or early autumn, the gain in size of plant and quantity of bloom is very great.—C. T., *Ampthill*.



HOW TO STOP CHRYSANTHEMUMS.

CYPELLA HERBERTI.

THOSE who are making out orders for half-hardy bulbs and such-like for spring planting should give Cypella Herberti full share of attention, for there are many things of the sort at four times the price which are not nearly so good. This is a South American irid of the utmost elegance and distinction, attaining, with its slender, but wiry stem and spare, grassy leaves, some two feet. At the tips of these growths the flowers appear in June, and these, over two inches across and in form somewhat like a tigridia, are a refulgent tawny orange, thus affording a note of colour which always attracts attention

Though the blossoms of C. Herberti do not last long, they are produced in extraordinary abundance, a good group yielding an unbroken succession from midsummer to autumn. Although classed as half-hardy, this plant appears to be quite robust enough for any conditions that a montbretia will endure, the soil, of course, being light and gritty and the aspect warm and sunny. The bulbs should be planted in March, 6ins. deep and about 4ins. apart in groups. C. Herberti is not a novelty, being introduced almost exactly one hundred years ago.—A. T. J.

BUDDLEIA ASIATICA.

MANY are acquainted with different forms of Buddleia variabilis, but few know what a desirable plant B. asiatica is for the cool greenhouse. It was introduced from India in 1874, but, so far, it does not appear to be a very popular plant. During January and February a few examples were making a fine show in the conservatory; they were about 5ft. high, with upwards of twenty-five sprays of bloom. The flowers are small and set in dense long racemes and sweetly scented. This is altogether a desirable graceful shrub. No doubt the best effect would be produced if it was planted out, but few have the necessary space, so the next best thing is pots and young plants. Old specimens do not respond well to pot culture, unless very large receptacles are used. When the plants have flowered they are cut back, and in a few weeks will produce numerous young shoots suitable for cuttings. These will readily form roots in a close propagating frame, and when rooted, should be potted off singly. If moved on as required they will make nice healthy specimens in 6in. and 7in. pots. A mixture of loam and leaf-mould will suit them.—T. W. B.

THE SELECTION OF TOOLS

BY R. V. GIFFARD WOOLLEY.

THE average amateur does not devote nearly enough thought to the choosing of his garden tools. Such proverbs as "Call a spade a spade" and "A bad workman blames his tools," seem to convey to some people the idea that all spades are much of a muchness, and that, in general, tools vary little in quality. Never were there more mistaken notions. A workman who has to use an unsuitable type of tool may justifiably blame it, unless, indeed, he selected it himself.

The most important of all garden tools is the spade. When purchasing one for one's own use, select a No. 1 size and see that it is by a good maker and properly finished off. It is important that the stock fits snugly into the straps above the langet, leaving no rough place to tear or blister one's fingers as they slide up and down, while the blade of the tool should be smooth front and back. The paint which is usually applied to the top half of the blade may cover a great deal of want of finish, but cannot conceal it if a close inspection is made. Above all, be satisfied that the tool comes nicely to hand and is well balanced. Since the weight of the tool comes upon the digger (plus that of a panful of soil), with every spit that is turned, it is advisable to get as light a tool as is consistent with rigidity and strength. The use of saw steel for spades is a modern development, important principally because of the saving of weight involved.

Some like treads on the top of a spade, others prefer a "clean" blade, which is easier to free from dirt and does not foul itself so quickly. Amateurs, as a general rule, seem not to like foot-irons, which are essential with an untreaded spade, but there is no reasonable argument against their use, and I strongly recommend the untreaded tool with a nice light (and short) foot-iron. Get the local blacksmith to make one to fit the gardening boot with which you dig—left if you dig right-handed, the right if you are "caggy." It is certainly advantageous to dig freely with either foot, but few can manage it.

Nowadays the garden owner very usually undertakes the purchase of tools for the staff, and there has, in consequence, been an increased demand for No. 3 spades and other out-sized tools. A "No. 3" is a fearful "weapon" for digging in heavy or even medium loams, and upon peaty or sandy soils there is no advantage in the use of so clumsy a tool, unless, perhaps, for shovelling. Buy the tools of the type favoured by those who have to use them—it is not easy to change one's working style to suit a strange tool—and pay as much attention to their finish and balance as if you had to use them yourself!

The fork is, compared with the spade, a fragile tool and even from the very best makers one sometimes buys a "dud." If the steel is a little too soft, the tines, or some of them, will bend, or the whole tool may "give" a little at the langet, in which case it becomes practically useless at once. If, on the other hand, the steel is over-tempered, the prongs are only too likely to snap in use. "Cheap" forks are even worse than "cheap" spades—avoid them! Forks are usually made with either four or five prongs, the former being better for heavy and the latter for light soils. A digging fork should be moderately straight in the tine, with a fair "lift" from the langet, but not too much. For lifting potatoes, herbaceous plants and so forth, more curving tines are desirable, but it is practicable to lift a crop with the digging fork, whereas one cannot dig with a lifting fork. For breaking up new ground, for trenching or bastard-trenching land with a stony sub-soil, a proper trenching fork with substantial tines, and strapped back and front right up to the handle, should be employed. An ordinary digging fork is almost certain to break or bend if used for the purpose, and if it does neither, one is wearing out at an excessive speed an especially good tool! A narrow "ladies'" fork is useful for pricking over the soil in a herbaceous border.

The three essential tools for working the soil are the spade, the fork and the hoe, and hoes are of two distinct types, the one which works on the push being called the Dutch hoe, and the other bearing the descriptive name of draw hoe. From time to time a controversy arises as to the comparative worth of the two types. On stiff loams wanting in lime, the Dutch hoe is practically useless and on *all* soils the draw hoe as commonly supplied for amateurs is next door to useless. On light and not too stony soils the Dutch hoe, in the hands of one who understands it, is invaluable and speedy in operation. On soils of awkward texture, or where paths have been tramped, a smith-made draw hoe with detachable plates—usually made from an old scythe blade or other cutting steel—is splendid, and a draw hoe is, of course, the proper tool for earthing up rows of peas and so forth. Four blades will be enough for most purposes, these being 4ins., 5ins., 6ins. and 7ins. long respectively. Most amateurs would do well to take a lesson in the proper use of both types of hoe from a skilled professional.

There are spades, forks and hoes made rather to sell than to use, but they do not force themselves upon one's attention quite so much as the tinned-iron trowels and impossible hand-forks which seem so plentiful in even good-class shops. A trowel should be made of the best steel so that it will ring musically if knocked and should be compact—I have just measured a very good one and it is only 11½ins. long from blade-tip to end of handle. It should be cranked and have a lift which brings the tip of the blade back approximately to the line of the handle-centre. One with a blade about 3½ins. wide is the most useful size, but a tool of otherwise similar construction, but with the blade almost flat and only 2ins. wide is useful for the rock garden, and also, if one does any, for "collecting." The hand-fork, except that it ought to have three flat tines, pointed at the tips, instead of the blade, should be of similar construction to the trowel. Hand-forks with the tines twisted to bring them parallel to one another choke badly in work.

Steel-shod dibbers are very useful for putting out cabbages and other plants which take root readily, but quite a useful dibber can be made from the handle of a spade or fork which has worn out or become a casualty. Dibbers for pricking off small seedlings should be made of boxwood and, so far as I know, one has to make them oneself or procure them

Digitized by Google

from a working gardener who has had a box tree to grub up.

A garden line made of whipcord is very desirable, and the proper spool upon which to wind it convenient, yet many good gardeners never use anything but two sharpened hardwood sticks to carry the line, and with a little practice, one can wind it on to such a stick almost as quickly as on a reel.

Old time gardeners found a worn out muck fork with the tines turned over at right angles, or a garden fork similarly treated and mounted on a broom stick, a very useful tool for stirring the surface of the soil after rains had beaten it down. A better balanced device with spring-steel tines, bearing cultivator teeth and called the "Buco" has now been on the market some years and is very recommendable.

For all but the smallest gardens the Planet Jr. double wheeled cultivator with detachable and adjustable tools for hoeing, earthing up and so forth, is a big labour saver; its use is, of course, confined to kitchen garden, fruit garden and nursery or cutting beds. For places where potatoes and green vegetables are grown largely, perhaps on plough land, the Planet Jr. horse hoes are excellent. They may be used to cultivate and earth up, as well as to clear out weeds quite close to the plants.

Spades, forks and trowels should be freed from earth as the work proceeds with a small, home-made wooden cleaner.

Apart from the kinds used in working the land, garden tools divide themselves into two classes, lawn and path tools and those for pruning, trimming and grafting. The former partake of the nature of machinery and could not have justice done to them in an article such as this. Coming then to knives, shears and scissors, a good pruning knife should be available in every garden. I never use a knife myself to prune roses, but for trimming up wounds after the saw, for shortening stakes and for many other jobs which are always cropping up, this tool is invaluable. The more expensive makes are here, as usual, well worth the extra money. The amateur will be well advised to select a tool with a "good deal of draw," that is to say, with a reasonably hooked blade. As essential as the knife, where a good deal of heavy pruning has to be done, is the bill-hook, and for this purpose a rather light tool with a narrow blade is the most useful. It will come in, too, for trimming pea and bean sticks and such like. The question of secateurs is a vexed one; there are a hundred and one patterns, most of which have something to recommend them. I have a little pair of secateurs in use now with an attachment to enable me to reach over and pick a flower, gripping the stalk by an attachment on the head of the tool. Their really strong point, however, is that they do not pinch the fingers; at least, the makers say so, and I thought myself that the tool was "immune." I lent them to a friend to try and he pinched a finger badly inside two minutes! Perhaps that is why I really favour plain, springless pruning scissors. These have their drawbacks, however, due mainly to their want of draw-action, which means that unless kept really sharp they are difficult to use and bruise the wood badly.

Scissors and secateurs should be rubbed up on a suitable soft stone every few minutes during use, and need grinding pretty often if given at all heavy wear. For this reason owners of large gardens should always invest in those with detachable and renewable blades.

Pruning grips are another problem. Most of the makes on offer seem satisfactory, but the simpler-looking this kind of tool is, the better, as a rule, it functions. As regards hedging shears, for any but the smallest garden it is wise to buy a pair which adjust by lock-nuts and a spring washer rather than by a rivet. The former kind are, in addition, rather easier to grind. We have all noticed that the strongest parts of a hedge tend to get higher at each cutting in comparison with the weak places, and the time comes when we want to cut into the hard wood to level things up. That is where a "grip" arranged near the fork of the blades in some makes comes in very useful.

And now, what other edge-tools does one need? Well, all gardens, except the very smallest, need a fagging hook; not an expensive tool, but see that the blade is nice and tight in the handle; they often aren't! Long handled brushing hooks are quicker to use than a pair of shears for hedge-trimming and in skilled hands do better work, but they are awkward for a novice and few seem now to understand their use. A hedge should be brushed downwards, *not* upwards and in the writer's view, at all events, the blade should be only moderately curved. For grafting the pruning knife will come in handy, while for budding roses and fruit trees proper budding knives are sold. These are made of razor steel and tempered just like the barber's tool, and as they need frequent sharpening, their life, if used a good deal, is not long. They are made in various shapes to suit different tastes, but the beginner would do well to select rather a small one with the back blade longer than the front. There is little to say about pruning saws. One often sees carpenters' saws in use for the purpose, but this no doubt is a case of "making do," though they answer well enough except in tight places.

All tools should be thoroughly cleaned before being put away, and if they are not to be used again for a considerable time, should be wiped over with an oily rag, or better, with one smeared with vaseline.

CORRESPONDENCE

GERANIUM ATLANTICUM.

THIS species appears to be quite uncommon in gardens and one rarely sees it offered in the trade lists. It is, nevertheless, a geranium of no little distinction and one well worth a place in the mixed border, woodland or rock garden. As to its merits, G. atlanticum is, in the first place, an early bloomer, coming into flower in spring, the cup-shaped flowers borne on an erect stem some 10ins. in height are a violet-blue suffused with plum-red. Thus, in colour, they closely resemble those of G. ibericum, but they are of about one-fourth the size. The foliage consists of deeply and finely cut round leaves and a colony of the plant makes a dense mat of pale green verdure some six inches in depth after the style of the wood anemone.

At midsummer the foliage of G. atlanticum commonly dies down, to re-appear with the autumn rains. With us this leaf growth continues to develop during mild intervals throughout the winter and it appears to be frost-proof. G. atlanticum resents disturbance and it is obvious that the best time for planting is full summer, or as soon as may be after the leaves have disappeared. The fleshy, carrot-like root makes off-sets freely so that propagation is a simple matter. We grow this geranium in ordinary free woodland loam, enriched with leaf-mould, in partial shade. A cool, moist root-hold during the flowering season is desirable, but the soil can hardly be too hot and dry during the later summer. This combination may be a somewhat difficult one to provide, but it seems to be essential to free blooming.—N. WALES.

DAFFODIL OR LEEK?

IT is recorded, but how far authentically the writer does not know, that March 1st in every year is the anniversary of St. David, that St. David is the patron saint of Wales, and that on that day Welshmen wear or wore a leek in their caps by way of commemoration.

St. David is stated to have advised King Cadwalcar that his Britons taking part in the battle on March 1st should, to distinguish them from the enemy Saxons, each wear a leek in his bonnet or cap.

The sand-leek, which is said to be wild in Britain, is very rare, and as an emblem the leek (even as cultivated) would not be very prominent or distinguishing.

The point one wants to raise is whether the daffodil was not the distinguishing mark which the Britons wore.

It (viz., the common daffodil, N. Pseudo-Narcissus) was common in woods and thickets in most part[illegible]ountry.

"Daffodils which come before the swallow dares" should have been plentiful in Wales on March 1st, the date of the battle.

Moreover, the name is suggestive of David or Taffid. Perhaps some learned Welshman who knows all about the subject will enlighten us.—PARKER WOODWARD.

KING ALFRED DAFFODIL.

IT may interest some to know that Narcissus King Alfred is not always such a failure as described by the Rev. Joseph Jacob (page 132). My bulbs do bloom in the open, and a few years ago one perfected a full head of seeds. I sowed three in a pot, plunged outside, and in course of time had nine or ten bulbs, and one has given a real "K. A." bloom already, not having been crossed with any of its neighbours. I anxiously await further blooms. Very numerous are the seedlings which spring up, some in a "wild garden" in the grass—notably from a Swiss importation, and pallidus præcox also.—I. H. PÖE (Capt.), *Riverston, Nenagh.*

I HAVE read the Rev. Joseph Jacob's note on this fine variety (page 132), but I can assure readers of THE GARDEN that the Cornish climate is not a necessity. I obtained bulbs from Messrs. Carter and Co. more

Digitized by Google

than twenty years ago, and, while they have not increased so fast as Emperor, I have now a good stock growing in the open border. It is the soil as much as climate that seems to be the deciding factor, with me at least. This daffodil likes, as far as I can make out, a good loamy soil, but does badly in retentive clay or anything approaching it. In very light soil it should be lifted and replanted more frequently to keep it vigorous. My practice is to lift all daffodils every second year, take such of the better bulbs as I need for pot culture to have early flowers in spring, and replant the offsets, which two years later have grown into good forcing bulbs.

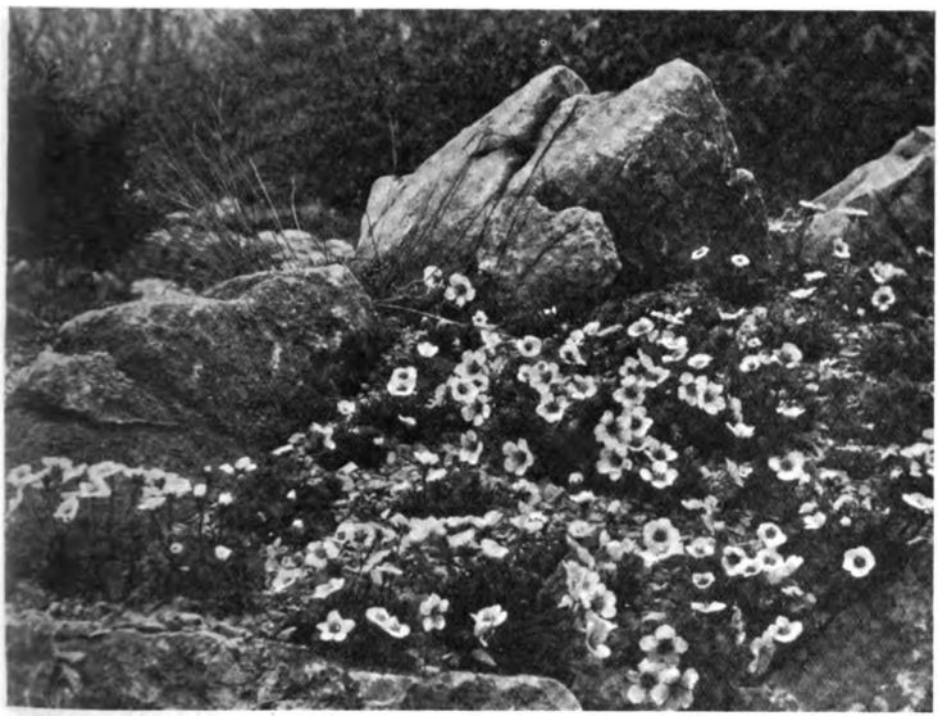
The climate here, in Kincardineshire, about six miles from the North Sea but sheltered somewhat from the worst effects of the east wind by a low ridge of hills, is far from being Cornish, but all the same it is not too bad to get good results in the garden, where there is shelter by belts of trees and the lie of the ground.—WILLIAM LOW.

SAXIFRAGA BURSERIANA.

I AM sending you a photograph of a group of Saxifraga Burseriana which I took in my rockery a month ago.

The plants were collected eighteen months ago in one of the steep gulleys running into the Adige Valley, and were planted out in a moraine mixture containing a large proportion of limestone grit a few months later.

The mild spell, which lasted for ten days or a fortnight before the present wintry weather, enabled the flowers to develop very well. My garden is within less than three miles from the centre of Birmingham, and, of course, the climate is cold and sunless.—ROY PINSENT.



A BEAUTIFUL DRIFT OF SAXIFRAGA BURSERIANA NEAR BIRMINGHAM.

DO WHITE FLOWERS OPEN FIRST?

THIS interesting question is raised in THE GARDEN (page 51) by "J. J." while discussing the merits of Hyacinthus amethystinus and its white variety. He says that the point was suggested by the late Miss Hope of Wardie Lodge, Edinburgh. The best way to settle this question would be to grow various plants and their white varieties side by side to see which would open first. With the flowers in different parts of the garden one does not readily notice which of the two actually opens its flowers first. I have noted a tall tree of the old white lilac (Syringa vulgaris alba) brightening a garden year after year, while its flowers became discoloured and were falling just as the common lilac came into beauty. It is my impression that this is merely a precocious variety, for Mme. Lemoine, which is double white, flowers later. This would apply to the single and double hawthorn. I have also grown the typical and the white Sisyrinchium grandiflorum, but not side by side. In the wild state I have seen Scilla festalis, Ajuga reptans, Campanula rotundifolia, Calluna vulgaris and their white varieties all blooming simultaneously, but that does not prove whether or not the white variety opened first. The red-tinted daisies seem most plentiful in spring, especially in exposed positions.—J. F.

WISTARIA BUDS DESTROYED BY BIRDS.

CAN any reader of THE GARDEN advise in this distress? For years an old wistaria smothered with its delicious trusses has been a delight. It is one of the joys of the floral year. For the first time last year, just as the stout buds were lengthening out, they were attacked, and practically every floret was nipped off. Sparrows are the suspected culprits — we hope the tits are guiltless— and were seen at the fell work. What is the remedy?

A Norfolk trap is at work, which means hard labour repeatedly letting out angry tits and flustered robins. Some of the sinners will not eat of wistaria buds again. But many, many sparrows are left, and possibly some preventive might be used.

Has any other victim suffered in the same way, or found a remedy? Has spraying with quassia or Horticol proved effective? This is not a little grief, for nothing can replace lost wistaria buds.—J. M. HOPKINSON, *Sutton Grange, Wansford, Peterborough.*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Lettuces are always in demand, and to keep up the supply a little seed should be sown every fortnight. Both cabbage and cos varieties should be selected, and directly the young plants are large enough to handle, thinning should be resorted to. If necessary, some of the seedlings may be transplanted. Lettuces need liberal treatment, and the ground should be well manured. During a dry period afford the plants plenty of moisture.

Radishes.—Frequent sowings should be made, and to secure crisp, succulent roots the resultant plants need to be grown quickly, and not allowed to suffer from lack of moisture. Protect the seeds from birds.

Celery.—Seed may now be sown to produce plants for the main crop. Solid White and Sulham Prize are both reliable varieties. Sow the seed in boxes containing light soil, and place them in a warm greenhouse to germinate; failing this, a cold frame arranged in a warm part of the garden will suffice. When the seedlings are large enough, prick them off in a cold frame which contains a few inches of loam and leaf-mould. Where only a small number of plants are needed, boxes may be used.

Beet.—A small sowing of a turnip-rooted kind made now, will produce useful roots during the summer months. Sow in lines 12ins. apart and if the seed is sown thinly no further attention will be needed beyond keeping the ground clean.

THE FLOWER GARDEN.

Single Asters.—These are rapidly coming to the front, both for cutting purposes and garden decoration and they will thrive in almost any position. They produce seed freely and if some is gathered at the end of the season it will be found useful for scattering in any part of the wild garden the following year.

Poppies.—The Shirley poppy is a very showy annual and seed may be sown any time during the next two months. It is advisable to sow the seeds where the plants are intended to flower, because the seedlings do not readily transplant. Bold patches or beds are the most effective, and the seedlings should be thinned to 6ins. There are many other useful annual poppies.

Sweet Peas.—Plants raised in pots will be ready for planting out, and seed may be sown in the open ground. Choose an open site and a rich piece of ground.

THE HARDY FRUIT GARDEN.

Wall Trees.—Specimens that have been planted this season will have sufficiently settled in the soil to enable the necessary tying of the shoots to be done. With all wall trees ample room should be left for the development of the growth when tying in, or the tie will cut into the bark and injure the wood.

Peaches and Nectarines.—Where the trees are well established the soil around the base of the stems may be lightly forked over, taking care not to injure the roots. Afterwards give a dressing of fibrous loam with which is incorporated a sprinkling of lime rubble. They may then be mulched with decayed manure.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.).
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Asparagus.—The soil should be well raked on the surface and rows taken out about 2ins. deep and 15ins. apart, and the seed sown. The two varieties usually recommended are Argentouil and Connover's Colossal. Sow the seed thinly, and so give the plants space to develop and grow, and thus avoid having to disturb the roots in future.

Brussels Sprouts and Savoys.—Plants raised from seed sown last autumn should be set out now on well cultivated ground, in lines 30ins. apart and 18ins. between each plant in the lines. Savoy cabbage and Drumhead should be planted at the same distances.

Onions.—If plants from autumn sown seed have done well throughout the winter, they should be set out in lines 15ins. apart and 6ins. or 8ins between each plant in the lines. Onions should be carefully handled and planted with a trowel. By using a trowel, sufficient soil can be taken out at each station to allow of the roots being well spread out.

Celery Trenches.—The ground from which Brussels sprouts have been cleared forms a suitable position for these trenches. The number to make must be regulated in all cases according to requirements.

Tomatoes.—If plants are grown in prepared beds, these should be made up now and the plants set out and properly staked. Continue to maintain a genial growing temperature.

THE FLOWER GARDEN.

Chrysanthemums.—Old plants should be lifted, and if very large split up. If the plants have not to be transferred to another border, place some old manure or leaf mould at the base of each station before replanting.

Gladioli.—Where corms have not been forwarded under glass they should be planted 4ins. deep in the beds or borders. If the soil is inclined to be heavy a little sand should be placed underneath each corm.

Lawns.—The mowing time is hastening on and the work of sweeping and rolling the grass should be taken in hand.

THE HARDY FRUIT GARDEN.

Apricots.—At this season we are stil liable to get frosts and snow and it is advisable to protect the flowers, as no doubt a few will be open here and there on the trees. Ordinary herring nets are often used, but we find that small birds get through these and pull off the flowers. A net with a ½in. mesh is therefore to be recommended.

FRUITS UNDER GLASS.

Orchard House.—Cherries, gages and plum trees should now be in flower, and the work of pollinating should be carried out daily, while the structure should be well aired.

Vines.—The bunches in the early house should have the shoulders, *e.g.*, side top portions, tied up with matting. This work if done carefully makes, as a rule, better shaped bunches, and to some extent lessens the thinning.

Strawberries.—These plants should be in flower now and the blooms should be gone over daily with a rabbit's tail to secure pollination; air, too, should be admitted on all favourable occasions. Careful attention should be given to the watering, as on no account should the plants be allowed to get dry at the roots.

DAVID ARMSTRONG.

(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Begonia Gloire de Lorraine and its varieties that were partly cut back early in the New Year for the production of cuttings should have now developed a quantity of shoots from the base suitable for cuttings. These will root readily if inserted in pots containing sandy soil and placed in a warm propagating case. It is important that the cuttings should be made from basal shoots; if taken from shoots off the stem they generally persist in flowering and never make free-growing plants.

Begonia gracilis is a tall graceful species, with beautiful pink flowers. This species is generally known in gardens as B. Martiana. The tubers should be started in a warm house, afterwards growing the plants in greenhouse temperature. As it finishes flowering this begonia develops bulbils on the inflorescence. These form a ready means of increasing the stock.

Begonia Evansiana (syn. discolor) develops bulbils in the same way. This is a very old garden plant, being introduced in 1812. It is almost hardy, and is very useful in the conservatory during August and September, when interesting and beautiful plants are rather hard to find. Fine examples can be grown in 6in. pots. This plant grows freely in any good potting compost, and only requires cool greenhouse treatment at all stages of its cultivation. Plants that have been kept dry and have started into growth should now be shaken out and repotted into small pots, afterwards potting them on as they require it.

Begonia fulgens is another beautiful variety which is deserving of more general cultivation. It has tuberous roots, which should be started into growth in a warm house at this time. When growth is a little advanced, this plant only requires cool greenhouse treatment. Begonia Davisii, with vivid scarlet flowers, and B. Pearcei, with yellow flowers—both progenitors of the present-day race of tuberous-rooted begonias—are worthy of more general cultivation for the conservatory, as both succeed under the same treatment as that accorded the ordinary tuberous-rooted varieties.

Tuberous-rooted begonias that have been placed in boxes and started into growth in a warm house should, when they have made 2ins. or 3ins. of growth, be placed in suitable sized pots, which will vary according to the size of the tuber; but care should be taken not to over-pot them at this stage These plants enjoy a light rich compost, and in their next shift a larger proportion of loam should be used. Young plants raised from seed sown early in the year should be kept growing freely, by giving them frequent shifts into a light rich compost. In their younger stages they are best grown in seed boxes or pans, afterwards planting them out in a bed of rich soil in cold frames.

Capsicums in their many varieties are very useful for furnishing the stages in the greenhouse towards the end of summer, as their bright and curiously shaped fruits always attract attention. Seed should be sown in a warm house towards the end of this month. The young seedlings, when large enough to handle, should be placed singly in small pots, potting them on as they require it until they are in 6in. pots, in which they will fruit. These plants should be grown in a house with an intermediate temperature. Unfortunately, these plants are very subject to attacks by red spider and begonia mite. The former should be prevented by a free use of the syringe, and the latter by the use of Campbell's Sulphur Vaporiser.

J. COUTTS.

Royal Botanic Gardens, Kew.

BOOK REVIEW

THE JOURNAL OF THE KEW GUILD.

PAST and present Kewites will, no doubt, welcome the 1924 Journal which has recently come to hand. Of outstanding interest to present Kewites should be Mr. Turrill's article on the London University B.Sc. degree in Horticulture. Perhaps the most valuable part of the Journal is that devoted to the names and addresses of old Kewites and what they are doing. The frontispiece is of Mr. John Masters Hillier, Keeper of the Museums at Kew. Mr. Hillier is the oldest present Kewite and he has just entered his forty-third year of service at the Gardens. The Journal is well got up and the illustrations are excellent. The new Editor of the Journal, (Mr. E. G. Dunk), is to be congratulated on his first issue.

*THE JOURNAL OF THE KEW GUILD, 1924. Secretary of the Guild, Mr. E. G. Dunk, 197, Kew Road, Kew, Surrey.

ANSWERS TO CORRESPONDENTS

THE GREENHOUSE.

Greenhouse Plants Unsatisfactory (N. M. P.).—So far as we can see, the trouble with the plants has arisen either from fumes from the heating lamps or from their being allowed to become dry for a while when the temperature was too high. No fungus or insect is responsible for their present condition.

ROSES UNDER GLASS.

Rose Trees Attacked (T. W., Notts).—The rose shoots sent for examination are very badly infested with mussel scale, and if many trees are infected they should be sprayed with paraffin emulsion. If few trees are attacked it will pay to go over them armed with a blunt stick and soft soap solution and remove the scale completely. Watch carefully for the hatching of eggs, and fumigate immediately the young insects appear.

Name of Plant (R. H., Worcester).—Iris unguicularis (I. stylosa).

HARDINESS

SPRING is abnormally late this year, so late that the gardening calendar has gone awry, a state of affairs which seems to be causing some hesitations and doubts among our readers. We have received several letters complaining that our articles are more suited to gardeners in the south than to those who live in the north and in Scotland. The idea seems to be that we mention flowering and planting dates suitable only to the south of England and the home counties, but we have to take a mean. It should not be difficult to add or subtract a few days according to the locality in which one is situated.

It might be as well to quote extracts from a most illuminating table in the October number of the Quarterly Journal of the Royal Meteorological Society. This table consists of the mean dates of flowering of fourteen plants in various districts of the British Isles. The figures are the number of days counting from the beginning of the year:

	England.					*Ireland.*	*Scotland.*	
	S.W.	*Mid.*	*E.*	*N.W.*	*N.E.*	*N.*	*W.*	*E.*
Hazel	31	37	38	33	38	47	55	59
Wood anemone	94	103	100	97	98	92	105	115
Horse chestnut	133	136	136	143	141	137	148	150
Dog rose	155	156	152	166	161	167	165	167
Harebell	192	190	188	200	180	199	199	192

This table proves, without fear of contradiction, that in the early portion of the year the variation in flowering dates is large between west and east and is greatest between south-west and north-east. As the months advance the variation lessens, until about midsummer it is nearly uniform, with a slight advantage in favour of the east. Naturally, at this time of year our articles deal with plants whose interest is topical; in other words, with those whose variation of flowering time is great.

These letters, however, open up a very much more difficult question, that of the general hardiness of plants. Non-hardy plants may be divided into two sections, those which are definitely soft at all times of the year, and those which are liable to be cut in the spring by reason of their early growth. The first section can be dismissed from this article, because their weaknesses are easily recognised throughout the country. They may be planted out in summer, but all gardeners know their shortcomings and deal with them accordingly.

The second section is a much more serious matter, for here the question of locality has a great deal to do with it. It is obvious that the comparative absence of spring frosts gives the west a great advantage over the midlands and east, and there are numbers of plants which will thrive in Cornwall, Wales and the west of Scotland which are useless in the midlands and in the east. It must be remembered that there are few countries so handicapped as we are in often having a pseudo-spring which brings a warm spell during January or February; the garden then sleeps again owing to wintry conditions in March or April. The majority of our garden plants come from abroad, where they are not accustomed to such treatment. This, again, brings us to the curious fact that many plants, particularly trees and shrubs, will grow equally well in Cornwall, which does not often suffer from spring frosts, and in the extreme east where the east winds retard growth and where the pseudo-spring has not sufficient force to make plants burst into leaf or flower. I have tested this several times in the case of rhododendrons and other shrubs which are perfectly healthy with me on the east coast of Scotland and yet are so badly cut in the home counties as to be practically useless as garden plants.

It is only too common an occurrence to blame a plant for not being hardy when the fault is not that of constitution but one of ignorance of proper cultivation and of error in situation. Gardeners are only too inclined to judge all plants by comparison with the easiest to grow, which is a mistake, for half of the amusement in gardening is in being able to diagnose the requirements of a plant.

This season has been so peculiar that gardens in the midlands and in the north have a distinct advantage over those in the south and west, for the weather in the former has been consistently cold while the latter have already had a mild spell and are now suffering severely from spring frosts.

We shall try in future to give more notes from gardens in the north and in Scotland, but we also beg our readers to remember that we cater for a universal gardening public, and that we try to strike a happy mean between the subtropical and the cold gardens by taking the climate of the home counties as an average, a climate which plays more tricks than that of any other part of the British Isles.

PLANTS WHICH ARE CURIOUS & FASCINATING

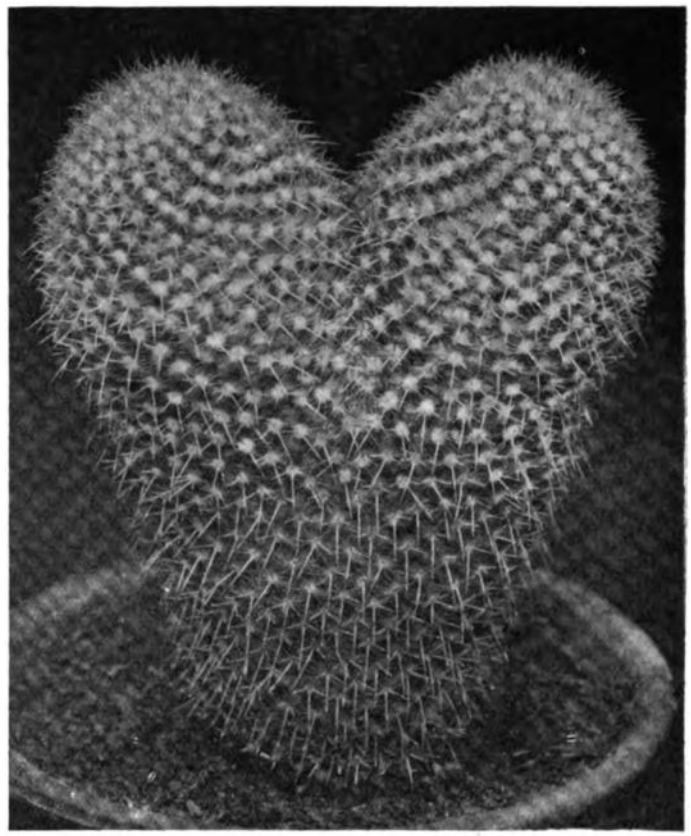
BY ROBERT W. ASCROFT.

CONSIDERABLE interest has been shown in the cacti and succulent plants exhibited at the Royal Horticultural Society's meetings by Mr. S. Smith of Falmer Road, Enfield. The study of cacti is a fascinating one, and it is a great pity that interest in these plants has been allowed to wane. In many parts of Europe the "craze" for cacti still continues, and there are growers on the Continent who list a vast number of species and varieties. Although well over a thousand species are now known, very few collections are to be found in this country, with the exception of certain botanic gardens, such as the Royal Botanic Gardens at Kew. The Carnegie Institution at Washington has published a very comprehensive monograph on this family, and another very fine work containing a vast collection of coloured plates showing the different species of cacti is a German treatise called "Bluhende Kakteen," by Professor Dr. Karl Schumann, over forty parts of which have been issued.

It is a curious fact, but one that exists nevertheless, that interest in any special plants—such as tulips, dahlias, sweet peas and cacti—rises and falls according to the popular fancy of the moment. The rich man and the poor man may grow cacti with equal success, and in the dry, heated atmosphere of small rooms, where most other plants are sure to fail, cacti will thrive and in due course produce brilliantly coloured flowers.

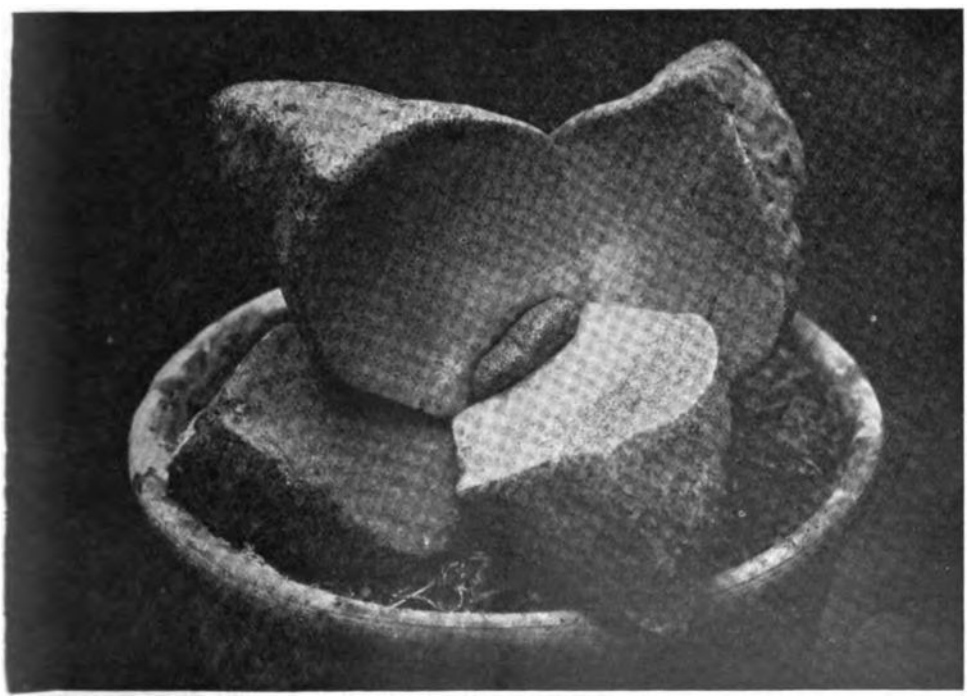
Cacti belong to the class of plants known as Xerophytes, and are mainly found growing wild in North and South America. The original form of cactus before it lost its leaves is the plant known as pereskia. The next stage is shown where the leaves are lost, the example being the prickly pear or opuntia, in which the so-called leaves are really branches. Seedlings of opuntia have one pair of fleshy seed leaves, while true cacti seedlings have none at all. A very curious feature about cacti is that the fruit is practically a bit of the stem with which the flower is incorporated. These fruits are very curious, and if placed on the surface of the soil will emit roots and form fresh plants.

We shall be sure to see many cacti this summer at the Wembley Exhibition, as collections of these plants have already been sent from Jamaica and other countries. In the Royal Botanic Society's Gardens, Regent's Park, there are some very interesting West Indian plants, and among them are specimens of the "Turk's cap" cactus, which belongs to the Melocactus group. These plants, which are oval in shape, bear on the top a cylindrical crown several inches high which, owing to its resemblance to a Turkish fez, both in colour and shape, has given the plant its name.



MAMILLARIA WALTONI RESEMBLES A SEA URCHIN.

Another curious cactus which is used extensively in Jamaica for making hedges, and which belongs to the genus Cereus, is the Dildoe cactus. This plant sometimes attains a height of 60ft.



MESEMBRYANTHEMUM BOLUSII. FAT LOOKING BUT ATTRACTIVE.

PROPAGATION BY CUTTINGS AND OFFSETS.—Although most cacti can be readily propagated from cuttings, it must be remembered that, owing to the presence of so much water in the plant tissues, any bruise is liable to form a source that may be subsequently attacked by the various species of fungi which cause decay. A sharp knife should be used in making the cuttings, and these should then be allowed to lie in a dry atmosphere for a day or two until a callus or cuticle has formed over the cut surface. The cuttings should not be inserted at all deeply in the soil or sand which is being used.

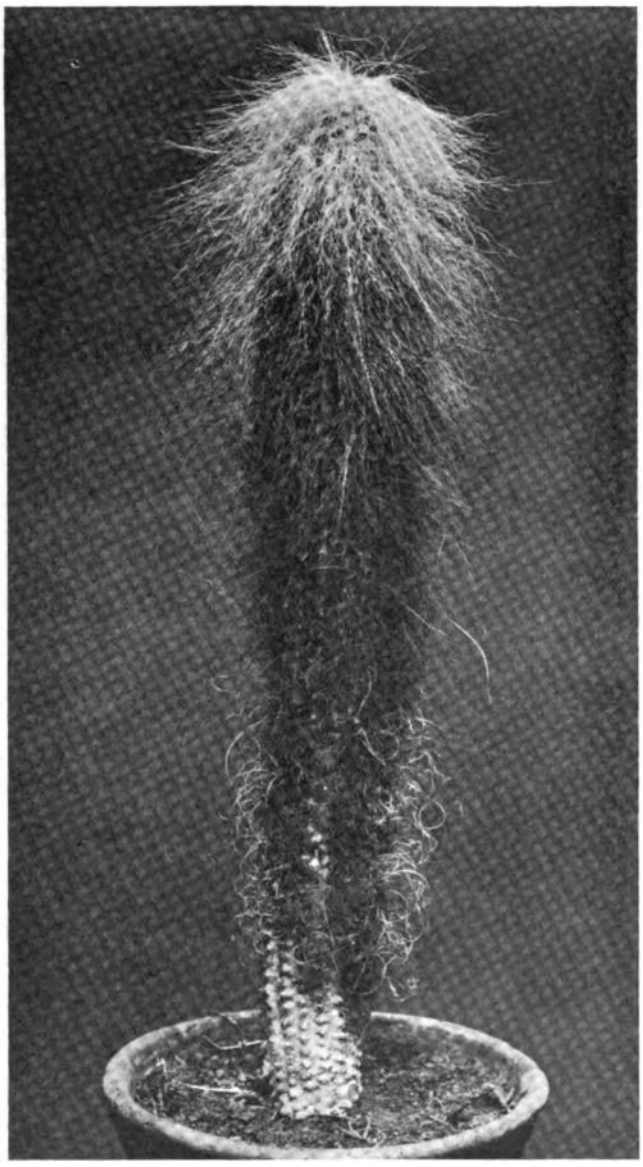
Mamillarias and some species of echinocactus may be increased by removing the offsets which form near the base of the stems, and these should then be treated in the same manner as has been described above. Species of cereus and opuntia can be readily increased in late spring and early summer by the removal of pieces of the young growth.

Light sprayings overhead will encourage rapid rooting. In many of the opuntias the fruits, if removed and treated as cuttings, will readily produce new plants. Grafting is frequently

Digitized by Google

carried out, but amateurs will probably be content to confine their attention to raising plants from seed or by the usual method of cuttings.

REPOTTING.—When repotting cacti any old crocks should be removed, but the soil around the roots should be disturbed as little as possible. The surface soil should be stirred so as to remove any weeds or green algæ. The growing months are between April and September, and the plants should be kept perfectly dry during the rest of the year from September to April. Start potting the plants in April in a soil consisting of loam, leaf-mould, sand, and old brick and lime rubble. Be certain that the pots are clean before use and add plenty of crocks for drainage. The plants can then remain for two



CEPHALOCEREUS SENILIS, "THE OLD MAN" CACTUS.

or three years before repotting will be necessary. Remember that too large a pot or too much soil invariably means failure. Another very valuable hint to amateurs, when potting, is to place a little piece of stone just underneath the plant. Many of the cacti require very little heat, and the temperature can go as low as 45° in winter. It should be remembered that the cereus and opuntia types need a certain amount of lime owing to the fact that they secrete large quantities of crystals of oxalate of lime.

FRUITS.—In the case of many species of cacti it will be found that the fruits are of considerable value, and in some parts, such as in districts in Mexico, the cacti fruits are eaten in large quantities by the natives. The outer skin is peeled away and the inner flesh containing the seeds is then eaten in a similar manner to an orange. The fruits of some of the opuntias and cereus group are used for the preparation of jams and jellies. One of the most curious uses to which cacti fruit is put occurs in the case of a Mexican species of cactus called Cereus pectenaboriginum, where the spiny fruit skins are dried in the sun and then used by the natives as combs and hair brushes.

FLOWERS.—The flowers of some species of cereus and phyllocactus attain a considerable size, and are often of a beautiful soft colour. Some forms bloom at night and are very fragrant. Although in the case of these plants the flower-buds open in the evening and the flowers die early in the morning, it will be found that a succession of fresh buds will open for some considerable time. Quite apart from their flowers, cacti are remarkably attractive in other respects. As a rule symmetry is one of the most characteristic features, and hairs, spines, ribs, etc., occur in regular order. When, on the other hand, monstrosities are met with, the plants are very remarkable, and amateurs obtain considerable pleasure from showing these plants to their friends.

The stems vary in form from the tall columnar cereus type to the round or globular melocactus and mamillaria. It must be remembered that cacti are exposed not only to scorching sun, but also to drying winds, and the thick fleshy stems have only, therefore, a very limited number of breathing pores so as to enable the plants to survive where others less suitably adapted to these conditions could not exist.

Many species of cactus are subjected to very low temperatures during the winter, and many cacti enthusiasts endeavour to keep their plants in too great heat during the winter. If they kept them in a cooler temperature just safe from frost the plants would grow far more quickly when the spring came round each year. Tropical species of cacti, such as some of the phyllocacti, will, of course, need greater warmth.

PESTS.—The chief insect pests which are likely to trouble cacti are the red spider and the shield louse. In order to keep these parasites from attacking them the plants should always be placed in a position both during the summer and winter where plenty of air is able to circulate freely between the pans. Once the pests have obtained a footing the best means of getting rid of them will be to examine the plants carefully and to touch any insects that may be seen with a soft brush that has been dipped in fir tree oil. No other rememdy will be necessary if the plants are gently sprayed with soft water early in the morning on bright sunny days during the summer months.

The chief cause of failure in the cultivation of cacti by amateurs is watering the soil too freely or standing the pots where they are exposed to drip from the roof of the greenhouse, with the result that decay sets in. Water should only be given in the early hours of the morning, and during the winter months the plants will go without any watering at all for weeks at a time. When it is found necessary to water the plants a thorough soaking should be given and the plants should then be lightly sprayed so that they may be dry by the afternoon. This light spraying will keep the pores open and free from dust. If a decayed spot is noticed, it should be rubbed immediately with a little slaked lime. Dust spells ruination to cacti, as it blocks up the pores and prevents the plant breathing properly.

HANDLING CACTI.—The best plan is to use pieces of very stout manilla paper cut into strips and wrapped round the thumbs and fingers. The ends should overlap and then be stitched back. Gloves are not suitable, as they are easily pierced by some of the sharp spines.

NOTES ON SPECIAL SPECIES.—Mamillarias should flower every year, and this also applies to the echinocacti. These plants should be kept in full sun during the summer months. Mamillaria Waltoni rather resembles a sea urchin, while Mamillaria plumosa is probably the only cactus which has branched spines, and in this case the minute feather-like spines are arranged in rosettes on the top of each tubercle. The spines are more like down than spines and the flowers are white with bright yellow stamens, the plant resembling a ball of soft down.

Mamillaria micromeris is a little gem and is covered with tufts of pure white spines. The flowers are large and star shaped, and the long carmine-coloured berries remain on the plant all the winter. The plant is easily grown, but dislikes any excess of water and needs keeping under glass so as to keep it white and clean. The plant only grows about six inches

Digitized by Google

high in forty years, and is found growing on very high mountains where no other vegetation will exist. When cultivated under artificial conditions it will be found that only about four applications of water a year are necessary.

Echinocactus Scopa rather resembles a bottle brush, and the whole plant is covered with short white spines. A rare and remarkable variety which is strikingly crested is Echinocactus Scopa cristata. Echinocactus minusculus is perhaps the prettiest of all the cacti with its numerous scarlet flowers, while Echinocactus Leninghausii is remarkable for its yellow hairs over a dark green cuticle.

Echinocactus Wislizeni is provided with very long and sharp spines which are bent in the form of a hook and account for the plant often being known as the fish-hook cactus. In North America the Indians use the hooks for fishing, and, as the spines when wet closely resemble worms in colour, no bait is necessary. The flowers are a greenish yellow colour, and are two or three inches in length and width.

Cereus grandiflorus and, in fact, all the varieties of this species bloom only at night, and the plants require shading in the summer. The flowers generally open about 7 p.m. and close again as a rule about midnight.

Cereus peruvianus monstrosus is one of the most strangely contorted cacti. Some of the branches swell out into curious crests many inches across, and the plant is most at home in a rather warm spot.

Pilocereus senilis is known as the "Old Man" cactus on account of the covering of long white hairs all over the plant and which resemble an old man's beard. Dust soon spoils the appearance of this curiosity of plant life, and for this reason the plant should be covered with a glass case if possible. Although in its native habitat specimens grow 20ft. in height, in this country it is a very slow grower. Opuntia cylindrica cristata closely resembles a cabbage leaf.

The Echeverias form a beautiful group of plants which differ greatly in the colour and texture of the leaves, while the mesembryanthemums belong to a very beautiful genus of succulent herbs or shrubs. The leaves are swollen and succulent, and the flowers are amazingly brilliant.

It is only possible to describe a very few of the many species, but I am sure that readers will agree that cacti deserve a little more attention than has been bestowed on them in the period since the war.

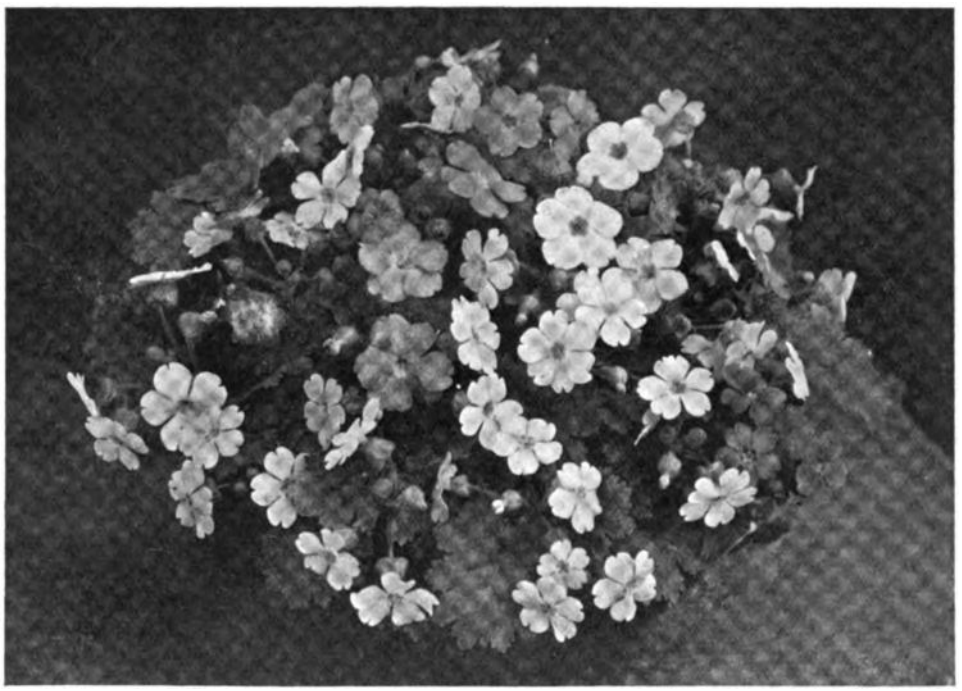
ATTRACTIVE BOWLS

A METHOD OF MASSING TOGETHER FLOWERING PLANTS GROWN IN TINY POTS IN A WAY WHICH IS BOTH USEFUL AND CHARMING.

FOR some years plants in pots and bowls have been growing more and more popular for house decoration, so much so that in many houses they have entirely ousted the cut flower. This is a move in the right direction, for growing plants last much longer in bloom and so are more economical. There are, however, one or two difficulties from which it is sometimes hard to escape, one is that of monotony of growth. The flower scape sticks upright in a pot, and is inclined to be stiff and ungainly. The days of those serried banks of potted greenhouse flowers towering up at the end of a Victorian drawing-room have disappeared and flowers for decoration are kept in smaller units, which are sometimes difficult to make attractive. Coloured and glazed pots are used, but are not always a success, and they do not assist in overcoming stiffness of growth.

At the Royal Horticultural Society's Show at Vincent Square on February 26th Messrs. Sutton and Sons had a small exhibit of Primula sinensis which was extraordinarily successfully arranged. It consisted of numbers of different varieties and colours of this primula grown in thumb pots and collected in large black bowls. So thickly were they grouped that each bowl constituted a tuffet of colour. The advantage of growing them in thumb pots is that the pots can be placed in the bowl at all angles and so any idea of stiffness can be avoided. The pots were packed in with moss, and the effect, as shown in the illustration, is very effective and with a grace which could not be obtained by growing the same number of plants in one pot. Also they are kept smaller in size in these thumb pots and are not allowed to grow long and lanky.

This method of growing plants for house decoration need not be confined to Primula sinensis. Many of the scillas and crocuses and such plants as small ericas and some of the dwarf varieties of begonia can be shown by this method with equal success. Crocuses, especially, will gain in grace, for if grown in clumps in one pot they are inclined to turn into a shapeless mass of colour and the charming shape of the flower is lost. By grouping ten or twelve thumb pots in a bowl the centre pots will be upright while those at the edge can be so placed as to stand at any angle to suit the flower and the contour of the bowl.



MANY SHADES OF PRIMULA SINENSIS ARE COLLECTED TOGETHER IN THIS ATTRACTIVE TUFFET OF COLOUR.

It is rather difficult to describe such an arrangement satisfactorily, but this method of decoration should certainly be tried, for a bowl of infinite variety in colour and shape can be arranged which will last in flower for a considerable period. Another advantage is that many shops keep tiny pots of flowering plants which can be suitably collected and massed together in infinite variety and at little cost.

A SELECTION OF SHRUBS for the ROCK GARDEN

BY W. IRVING.

SHRUBS that might be included under this title are so numerous that I only propose to deal with a small selection of the most distinct and easily grown kinds. Low-growing shrubs, apart from the dwarf conifers, are very valuable adjuncts for adorning the rock garden, giving it a furnished appearance during the winter months, and providing a charming display of bloom in season. Many of the following plants naturally inhabit the cold Arctic regions or high mountain chains, and when transplanted to our lowland gardens they preserve their alpine character, which makes them fit associates for the other plants grown there. With few exceptions they are easily grown, and, if only pot-sown and established specimens are procured in the first place and well planted, there need be no real difficulty with many of them. It must, of course, always be remembered that some plants are partial to certain soils and situations, so that it is necessary to learn their requirements before placing them in their permanent positions.

Among the best of the close-growing deciduous shrubs of creeping habit is Arctostaphylos alpina. The leaves are small, slightly serrated, netted and wrinkled; while the white flowers are succeeded by black berries. On the Alps this species usually grows in high altitudes in peaty soil, mostly damp, but it is also found in sandy or gravelly soil. Collected plants are difficult to establish; seeds are the best method of propagation. A. Uva-ursi is a well known and pretty evergreen of fairly quick-growing habit. The plant is trailing, with thick, smooth leaves, and bears pretty rose or white urn-shaped flowers, which are succeeded in autumn and winter by coral-red berries. It is fairly common on the Alps of Europe, and is also found on the mountains of this country. A. nevadensis is an American species very closely allied to the above.

Alyssum spinosum is a silvery-leaved shrubby species that forms rounded hummocks up to 1ft. high and several feet across. It bears, in early summer, white or pink flowers in terminal clusters and is a very ornamental plant. As its name implies, the old branches are spiny. It is a native of France, and soon establishes itself in suitable situations by means of self-sown seedlings, which have a preference for rocky crevices.

There is a fine genus of small trailing shrubs called bryanthus, which is closely allied to loiseleuria. They require to be grown in sandy peat in a partly shaded situation. B. Breweri, from North-western America, grows about 9ins. high with numerous stems crowded with narrow leaves that have revolute, thickened margins. It is a charming little evergreen, with good-sized rose-purple flowers in short racemes during the summer. B. empetriformis, from the same region and of similar habit, has reddish purple flowers clustered near the extremities of the branches. It is only 6ins. high. B. erectus, from Siberia, grows about 1ft. high and bears red campanulate flowers.

The species of Cassiope are tiny alpine bushes somewhat resembling the heaths. There are four or five species in cultivation—C. fastigiata and C. selaginoides from the Himalayas, C. tetragona from Lapland, and C. hypnoides from Arctic Europe and North America. Until their requirements are perfectly understood they are not easy plants to grow, but when success is attained the plants are to be numbered among the choicest alpines for the rock garden. They appear to like a half-shady position and a moist peaty soil that is well drained; while stagnant moisture and drought are alike harmful. C. fastigiata comes from the north-western Himalayas where it grows at about 12,000ft. elevation. It is a beautiful free-flowering plant about 9ins. high. The flowers are solitary, white and bell-shaped, not unlike an andromeda. The five segments of the corolla are recurved and show the pink centre and curious awned stamens like the arbutus. The leaves are imbricated in four rows and have white membraneous margins. The other species from that region, C. selaginoides, is only an inch or two high, of moss-like habit, with white, bell-shaped flowers. C. tetragona is a more common but less attractive plant. The foliage has a more grassy green colour and the stems are more branching, while the flowers are only about half the size of those of C. fastigiata, and they are not produced so freely. It is easier to grow, and if the stems are pegged down they root quickly. The plant produces its little white, bell-shaped flowers in April, about a month before C. fastigiata. C. hypnoides is a creeping, moss-like plant bearing solitary drooping flowers on long stalks. It is very rare in cultivation and is one of the most difficult to grow in lowland counties. There is also another species in cultivation from North-western America, C. Mertensiana, of dwarf compact habit, but I have not seen it in flower.

A little-known trailing shrub is Chiogenes hispidula, with almost thread-like woody stems and small ovate leaves, light green and smooth, quite evergreen, the branches being covered with small bristles. The flowers are small, white, and in the autumn are succeeded by white berries. It grows best in a half-shady moist position in peaty soil. It is a native of North America, being found on the Alleghany Mountains.

Many of the daphnes are beautiful rock plants, such species as D. Cneorum and D. petræa when well established making charming groups. This genus was dealt with in THE GARDEN of May 26th, 1923, when all the different species in cultivation were described. All daphnes thrive best in slight shade, but will do without it if the soil is moist. Stones in the soil help to keep the roots cool and moist, and prostrate-growing species like D. Blagayana like their stems covered with large stones, these inducing them to root afresh. They are not deep-rooting plants, but usually make a mat of fibrous roots just below the surface. It thus follows that they are not able to withstand the dry conditions of a sunny aspect.

Empetrum nigrum is an evergreen of creeping habit with small linear leaves.

A DECORATIVE ROUNDED HUMMOCK OF ALYSSUM SPINOSUM.

Digitized by Google

The flowers are somewhat inconspicuous, rose-coloured, and the fruit is black. It is easily grown in peat and loam and is useful on account of its evergreen character. It is a native of this country.

One of the prettiest of the dwarf trailing shrubs is Epigæa repens. It is variously known as the May-flower and trailing arbutus. It is far from common, and many find it difficult to cultivate. In its native land, North America, it loves sandy and rocky woods, and delights particularly in the shade of evergreen trees. It is of distinct trailing growth, and the wood is hard and quite wiry, rough, and covered with rusty hairs. The leaves are rounded or heart-shaped. The pretty flowers, produced in terminal or axillary clusters, are salver-shaped, white or, more often, flesh or rose coloured, and deliciously scented. This plant may be grown in sandy peat under the shade of standard evergreens, but it is difficult to establish in situations under the influence of smoky towns. As a pot plant, grown in frames under a north wall, it is charming for the alpine house. The propagation of Epigæa is best effected by layering after flowering, which is generally from March to May.

Although Erinacea pungens has been in cultivation since the year 1759, when it was introduced from Spain, it is still rare in gardens. It is, however, quite hardy if planted in a suitable situation on a sunny, well drained ledge. Under those conditions it forms a much-branched, spiny and almost leafless little bush about 9ins. high and a foot or more across. The flowers are produced during the summer months, six or eight together, on a short inflorescence, and they are of a bluish purple colour. It is a somewhat difficult plant to propagate, but this can best be accomplished if the cuttings are inserted in sandy soil in the autumn and placed in a cold frame, where some of them will commence to grow the following spring.

Erica carnea and its variety alba are beautiful winter and early spring-flowering plants that are indispensable in the rock garden. They are valuable for planting in large groups and masses.

(To be continued.)

DAPHNE BLAGAYANA, A PROSTRATE-GROWING SPECIES WHICH GIVES A PICTURESQUE APPEARANCE TO THE ROCK GARDEN.

RARE TREES AND SHRUBS

BY W. J. BEAN.

NOTHOFAGUS DOMBEYI: THE COIGUE OF CHILE.

SINCE the introduction — or rather, re-introduction — of Nothofagus obliqua and N. antarctica from Chile by the late Mr. H. J. Elwes in 1902, a good deal of interest has been taken in the southern beeches generally. Although they are so closely related to our northern beeches that many botanists have placed them in the genus Fagus, they have much smaller leaves and are really very distinct, but perhaps more so in general appearance than in purely botanical characters. N. Dombeyi is a large tree, commonest in Chile and the island of Chiloé, but also native of the Argentine. Near the Baths of Chillán, at altitudes of 5,000ft. to 6,000ft., Mr. Elwes told me he measured two trees, one 27ft., the other 22ft. in circumference of trunk. It is rather remarkable that the introduction of so fine a tree—one of the chief sources of timber in Chile—should have been so long deferred. Mr. Elwes brought home seeds from the Argentine in 1902, but none of them grew, and we owe its existence in Britain now to Mr. F. R. S. Balfour of Dawyck, who obtained seeds in 1917 and sent them to Kew, where a few germinated. These, so far as I am aware, represent its first introduction to this country.

It is evergreen in South America, but the young examples in cultivation sometimes lose a good deal of their foliage in winter. The leaves are ¾in. to 1¾ins. long, half as wide, ovate to lance-shaped in outline, finely and sharply toothed, leathery in texture, dark glossy green above, paler but also bright green beneath, speckled freely on both surfaces, but especially beneath, with minute dark glands; leaf-stalk 1-12th in. long. Seeds three-cornered, like those of our common beech, but only ¼in. long. The young trees in cultivation are very elegant, making long shoots annually on which are set, horizontally and alternately, two rows of small lustrous leaves. As regards hardiness, they have not been put to any real test since their introduction, but at present are perfectly healthy.

CARYOPTERIS TANGUTICA.

In a good many gardens, in the South at any rate, Caryopteris Mastacanthus has for many years been valued for the beauty of its flowers, more especially as they open as late as September and October. It was first introduced from China by Robert Fortune in 1844, but subsequently disappeared from cultivation until Charles Maries sent it to the Coombe Wood nursery from Japan in 1880. If given a sheltered place, such as at the foot of a south wall, it is hardy near London in all but the severest winters. This new species, C. tangutica was originally discovered in Western Kansu by Przewalski

the Russian traveller, but the credit of its introduction to cultivation belongs to the late Reginald Farrer, who sent seeds of it home in 1915. As Fortune found the older species wild near Canton, where, I imagine, the climate is very much warmer than that of Kansu, there is every probability that this newer one will prove considerably hardier. At the present time (February) the shoots made last year are entirely fresh and healthy.

C. tangutica is a bushy shrub described as 3ft. to 5ft. high in a wild state, the young shoots, the undersurface of the leaves and the flowerstalks all clothed with a close grey down. The leaves are ovate, ¾in. to 1½ins. long, the terminal half coarsely toothed, dull dark green above. The flowers are borne in short-stalked clusters in the leaf-axils and at the end of the shoot and open in September. Each flower is about ½in. long, the corolla bright violet-blue, with four short entire lobes and one larger, longer, toothed one forming a "lip"; the calyx is ¼in. long, its lower part bell-shaped, but dividing at the top into five pointed, violet-tipped lobes.

This shrub belongs to the Verbena family and, like so many of this group, has a pleasant aromatic scent when crushed. It bears considerable resemblance to C. Mastacanthus, but differs in the smaller leaves with blunter teeth. It is easily increased by leafy cuttings in late summer.

CALLICARPA GIRALDIANA.

Several species of callicarpa are or have been grown under glass, the best known of them being C. purpurea. Another species, hardier but not completely hardy, is C. japonica, sometimes grown out of doors and very handsome when well furnished with its violet-coloured berries, each about the size of a peppercorn. But, near London, I think this newer species, C. Giraldiana, will prove to be the hardiest and best for cultivation in the open air of all the callicarpas. It is a native of western China in the provinces of Szechuan, Hupeh, etc., and was discovered by Professor A. Henry in 1887. It was introduced by Wilson twenty years later.

This is a deciduous shrub of erect habit growing about 6ft. high, the young shoots at first downy, soon becoming smooth. The leaves are narrowly oval or lance-shaped with a slender point, toothed, 2ins. to 5ins. long, 1in. to 2¼ins. wide, dull dark green above, paler beneath, downy on both surfaces; leafstalk ¼in. to ½in. long. The flowers open in July on the leafy shoots of the current season, crowded in roundish clusters in the axils of the leaves. Each blossom is about 3-16in. wide, the corolla lilac-coloured, with four rounded lobes; anthers yellow. But, while by no means devoid of beauty of flower, it is in late October and November, when the fruits are ripe and in full colour, that this shrub acquires its full charm. The berries are pale blue-lilac, glossy, each one ⅛in. to ⅛in. in diameter, and they are borne in roundish clusters at each node (or "joint") of the shoots, several dozens in each cluster.

This callicarpa likes generous treatment at the root and an open, well cultivated soil, and it should be grown in full sunshine. I do not know how it would withstand a winter like that of 1894–95, but it has not been affected by cold since its introduction. From C. japonica, which has smooth leaves and flowerstalks, this is easily distinguished by its downy ones.

THE ART OF GRAFTING

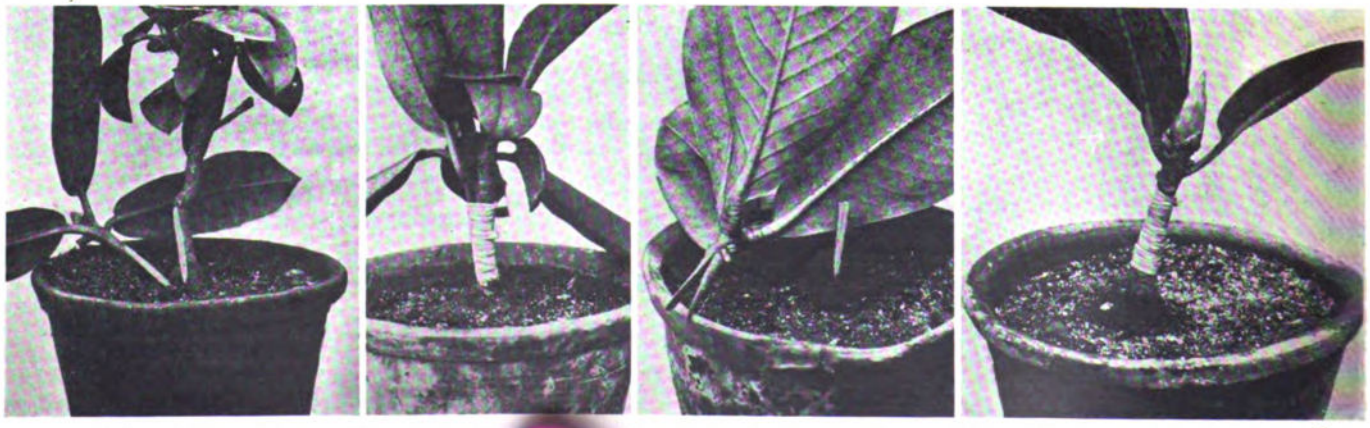
BY A. OSBORN.

GRAFTING is an important method of propagation. It is a means of increase which should be considered when seeds, cuttings, layering and division are not practicable or not in sufficient quantities to meet the demand. Important examples of grafting as a rapid means of increase include the large-leaved hybrid rhododendrons and the named varieties of clematis. Layering may be, and is in fact, a preferable method of propagating a few rhododendrons at home, but there are very few sufficiently large plants in nurseries to consider layering as a paying method of increase. The many beautiful garden varieties of clematis can be increased by cuttings and layering. To meet the yearly demands of their customers, however, nurserymen graft thousands annually. Letters appear in the horticultural Press from time to time attributing the sudden withering of clematis to grafting. There appears to be no reasonable ground for this statement. The trouble can usually be traced to the sun cracking, or the wind swaying and splitting, the fibrous bark of the lower parts of the stems.

The many varieties of hollies and flowering crabs can be readily and profitably increased by grafting. A certain amount of grafting is practised with the Japanese cherries, flowering peaches and roses, though budding in summer is preferable. The scientist regards budding as merely a form of grafting, but in the field of practice it is preferable to treat them as distinct methods of propagation. The nature of the wood of the prunus family in general does not lend itself to such a good, permanent and lasting union, the cambium of a single bud uniting better than a woody scion. On the other hand, we have the pyrus family in which there is nothing to choose between grafting and budding. Another reason for grafting is to infuse vigour into plants of weak growth and, if of weeping or prostrate habit, to get them up on stems well above the ground where their distinct habit of growth can be better seen and appreciated. Pendulous varieties of the beech, elm and holly may be cited as examples. Though some of the progeny of the copper beech or the cut-leaved beech may come true from seed, when grafting is practised we are sure of trees true to type.

With the increasing popularity of ornamental trees and shrubs the demands at the moment for a number of the new and rare kinds can be best met by grafting.

The skill of the propagator, however, in the practice of grafting can easily be overdone. There are some examples for which I can find no justifiable excuse.



THE FIRST AND THIRD ILLUSTRATIONS SHO[W] SCIONS AND STOCKS READY FOR SIDE AND SADDLE GRAFTING. THE SECOND AND FO[UR]TH SHOW THE RESPECTIVE OPERATIONS COMPLETED.

Digitized by Google

Osmanthus Delavayi is readily increased by cuttings. Plants we obtained from the Continent were grafted on Phillyrea. Apparently it was done to obtain quick growth, but it is a perpetual source of trouble to keep cutting off suckers. The privet is sometimes used as a stock for lilacs, which are freely propagated by layering and cuttings. A third example may be cited, namely, grafting cotoneasters on thorns, when increase is easy by seeds and cuttings.

As a rule, one or other of the common species of a genus is used as a stock, but occasionally, in practice another genus of the same Natural Order is used, as, for example, grafting Cytisus Dallimorei and Spartium junceum flore pleno on the common laburnum.

In addition to the desire for rapid increase, grafting is sometimes of value when our soil, climatic or other cultural conditions are unfavourable. The grafting of Clianthus Dampieri on Colutea arborescens and Halimodendron argenteum on Robinia, or Caragana, are examples. I am also inclined to attribute the healthy growth of several plants of Rhododendron campylocarpum outside at Kew to the fact that they are grafted on R. ponticum. Plants on their own roots are not doing so well, though probably this result would not coincide with bushes in the south and west.

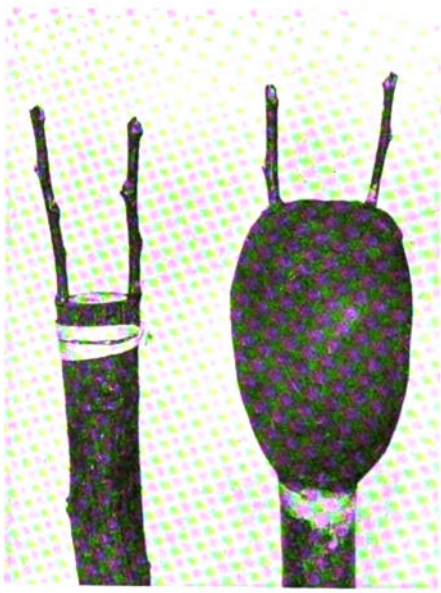
The best time for grafting most trees and shrubs is in spring, about April in the open, and from January onwards under glass, beginning and finishing with evergreens. Some grafting is also done under glass during late summer and autumn, oaks and rhododendrons being noteworthy instances As a matter of fact, the rhododendron is such an easy plant to graft that there is no reason why it should not be practised throughout the year, assuming increase is imperative from October to December, but not otherwise should it be done in the dull dark days of winter.

METHODS OF GRAFTING.—There are several slightly different forms of grafting, though the principle is the same, *i.e.*, the union of the cambium, or inner bark of the stock, and scion. The object, then, must be to so cut and fix the scion on the stock that as much of the cambiums as possible of both may coincide. With this end in view it helps very considerably when stock and scion are similar in size.

It being desirable for the sap in the stocks to be running freely, they should be placed under glass two or three weeks before the actual grafting is done. A larger percentage of successes may be looked for if the stocks have been potted some time previously. Outside, this advance of stock over scion is obtained by cutting off the wood for grafting and heeling it in the ground at the foot of a north wall or hedge early in January.

The average length of the cut surfaces on the scion and stock is about 1in., varying a little, more or less, according to the size of the wood and the kind of shrub or tree. The quicker the surfaces are united when the actual cutting is done the better.

In bush plants it is desirable to have the point of union low down so that there is less chance of sucker growths developing on the stock. When grafting on tall stems this objective cannot apply, but being a clean stem suckers are more readily detected than on bushy plants with branches near the ground. Another reason for grafting low down on the stock is that the point of union can be buried when replanting to encourage the



RIND-GRAFTING: MODE OF CLAYING.

scion to root and become independent of the stock in course of time.

When grafting under glass in a close, moist atmosphere it is sufficient to tie or bind the stock and scion together with raffia, matting or grafting cotton. Outside the point of union must be kept air-tight with clay or grafting wax.

SADDLE-GRAFTING is a favourite means of increasing the large-leaved rhododendrons. The stock is cut wedge-shaped, sloping on both sides as depicted in Fig. 3. The scion is cut up the centre and thinned to fit closely on the top of the wedge-shaped stock, hence the term "saddle" grafting. Care must be taken not to cut up the stem beyond the point of union desired with the apex of the stock.

SIDE-GRAFTING is the most generally practised method. With saddle-grafting it is imperative to have the stocks established in the pots. With this method it is also a great help, but as the top of the stock remains to draw up the sap until the union is assured the point need not be so closely followed. Fig. 1 shows the prepared cut surface of the stock ready to fix the scion resting on the pot at the side.

LIP-GRAFTING is a form of side-grafting, a groove or "lip" being made at the base of the cut surface on the stock into which the bottom of the scion will fit. This holds the scion more firmly in position.

If there is a difference in the size of stock and scion, place the scion on one side to ensure the union there of the cambiums.

TONGUE, WHIP OR SPLICE GRAFTING is a useful type of grafting, and one designed to hold the scion firmly in position. It is desirable that the sloping cut on the stock should finish just above a bud. A thin downward cut is made corresponding to an upward cut or "tongue" made in the scion. The parts are then closely fitted together and bound in position.

RIND-GRAFTING is largely practised with old fruit trees which through some cause or other it is desirable to graft with better varieties The branches are cut back a month or more before grafting time, leaving sufficient wood for a fresh cut to be made at the actual time of grafting. The scions may be 6ins. to 9ins. long. Cut 1in. at the base as is done with the ordinary side graft. The bark of the stock is next separated from the wood and the scion inserted. Several grafts may be placed round according to the size of the stem. After binding in position cover the points of insertion with clay or grafting wax. To keep the clay moist and prevent cracking, tie moss over the clay.

ROOT-GRAFTING.—This is the easiest and most adaptable of all forms of grafting. It consists in grafting small twigs or pieces of root taken from trees of the same species, or a closely allied genus. Important examples of trees and shrubs readily propagated in this way include wistarias, bignonias, tree peonies and clematis. It is a method of propagation giving abundant scope for the enthusiast to experiment with. Any tree or shrub proving difficult to increase should be tried. It is preferable to pot up all root grafts and start them in a close frame with gentle bottom-heat.

NEW GARDEN CLUB

THE very latest thing in London is the Garden Club—the resort of the best-informed and best-known people in the gardening world—and, judging by its long list of members, there appears to be little doubt that it is going to be extremely popular. At the inauguration reception recently there were present the Countess of Dartmouth and Lady Joan Legge, Lady Tenterden, Lady Eva Wyndham-Quin, Sir William Lawrence, Sir Ronald and Lady Russell and very many more gardening enthusiasts. Situated next to Princess Mary's town residence in Chesterfield Gardens, it was originally Lord Leconfield's house, and its position is ideal for a club. The furnishing of the beautiful library—with its original frieze of Cupids riding on dolphins, and its carved fireplace and bookcase to match—and of the dining and drawing rooms adequately conveys the title of the club. The floral loose covers to the deep-seated easy chairs and settees, the window-boxes in green and gold with growing flowers, and the latticework decoration to the walls of the lounge are in excellent taste. There are over thirty bedrooms for the accommodation of the club members, which have all been furnished in extremely good style, and the whole arrangement of the interior is most pleasing. A roomy lecture hall will be used for enlightenment on interesting subjects, and many new friendships among garden lovers will be made within the walls of this new club. The furnishing has been carried out by Messrs. Oetzmann and Co., Limited.

GARDENS in the MAKING at WEMBLEY

BY G. C. TAYLOR.

IT was with feelings of wonder and amazement that I regarded the British Empire Exhibition at Wembley Park in its last stages of completion on a fine sunny morning last week. One could almost imagine that one had arrived at some industrial urban area. Thousands of workmen were scurrying to and fro like a hive of busy bees. Buildings took shape, and became a reality, while one looked on. Trees disappeared suddenly from one spot to make way for something more substantial and one rediscovered them growing happily in a more secluded nook perhaps two miles distant. Roads are being quickly fashioned, with grass lawns bordered with young trees running along their length.

THE DARK SETTING OF THE PINES LENDS A ROMANTIC TOUCH TO THE SCENE.

Owing to the kindness of Mr. A. C. Bartlett, the Horticultural Superintendent at Wembley, I spent a very pleasant few hours looking round the area of some two hundred and twenty acres, paying particular attention to the gardens which are in the process of formation and which, when completed, will add a natural and beautiful appearance to the Exhibition—the green verdure and the colour of the spring flowers showing up in striking contrast to the whiteness of the buildings. Even the most wonderful exhibit would appear drab were it not enhanced by a touch of colour from Nature's palette.

One often wonders at the marvellous skill of the engineer and the builder, and their accomplishments at Wembley call for further praise in that direction, but the horticultural staff also come in for their due share of credit. To be presented with a veritable sea of mud and instructed to form and lay-out beautiful gardens in the space of a few weeks is to be given no easy or light task. And yet, such is being done at Wembley Park. Already a number of gardens are completed, some are nearly so, while others again still await the harrow before they can assume anything like the form of a garden.

From the north-west entrance one is confronted immediately with a broad open vista, in the centre of which there is a large grassy lawn with broad paths about 18ft. wide along its edges. Rhododendrons have been transplanted at intervals of from 6ft. to 8ft. along the sides, forming a pretty avenue. They are fine, bushy plants and are growing well. At the corners of the smaller squares and rectangles forming this lay-out one finds transplanted cypresses (Cupressus Lawsoniana). These were only transplanted about four or five weeks ago. At present they are protected by a canvas screen on two sides to guard them against the north and east winds till they become thoroughly established and attuned to their new conditions. It is an exceedingly novel way of affording protection, as the illustration shows. Other cypresses will be planted in tubs interspersed here and there throughout the lawn.

Mention must be made of the exhibits of the many horticultural firms which are gathered together in one area, where are being prepared gardens of flowers, shrubs and fruit trees, surrounded by well laid out grassy lawns, bordered with narrow gravel paths. These exhibits, while, as yet, only in their infancy, will indeed be a picture when completed and will give one an idea of the correct methods to be applied in landscape gardening, the use of hedgerow plants and shrubs and their value to their less bulky neighbours in a border, of the skill required in the maintaining of a lawn, with the necessary and up-to-date tools to be employed, and various other difficulties which oft-times confront the gardener in carrying out his duties.

Each of the Dominion buildings will be surrounded by a garden containing many plants indigenous to that particular part of the globe which the Dominion building represents. The exhibits will be world wide in their representation and thus should evoke considerable interest and attention among a large section of the British public, as it will bring home to the visitor the untold wealth of the Empire in all the various aspects of horticulture.

The fruit display will be one of the finest ever seen in this country, contributions coming from Canada, Australia South Africa and New Zealand. All the various kinds and varieties for which our Dominions are famed will be on show, and the exhibit will be sure to prove interesting and instructive to those engaged in the trade in Great Britain. Oranges. lemons, pineapples and soft fruits (in preserve) will be found in the South African building: while the apples will come from their well known home—Canada. Australia will show her fruit products from the garden, orchard and vineyard, many of which will be exhibited in a frozen state. New Zealand's raw fruits will be largely represented by apples and pears. Fresh consignments of these fruits will arrive throughout the period of the Exhibition, so that an excellent standard is assured.

The aid which scientific research renders to agriculture and horticulture in its manifold branches will be demonstrated by the Ministry of Agriculture in exhibits dealing with plant pathology, plant breeding, the chemistry and nature of soils, and horticulture. Much useful information will be gained by a visit to this stand in H.M. Building, where the theories and the research of the scientist

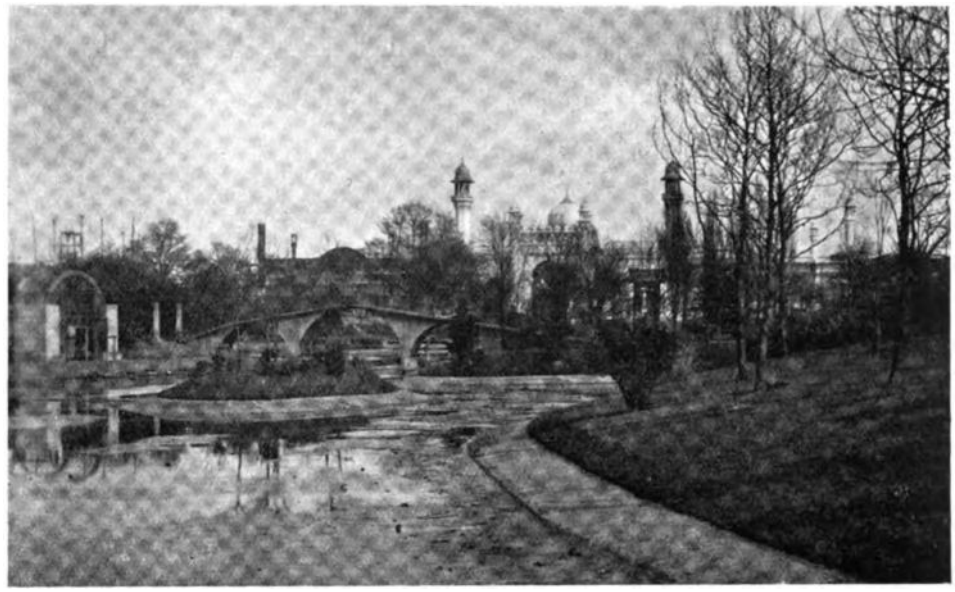
Digitized by Google

will be seen in their application to the present day practical problems.

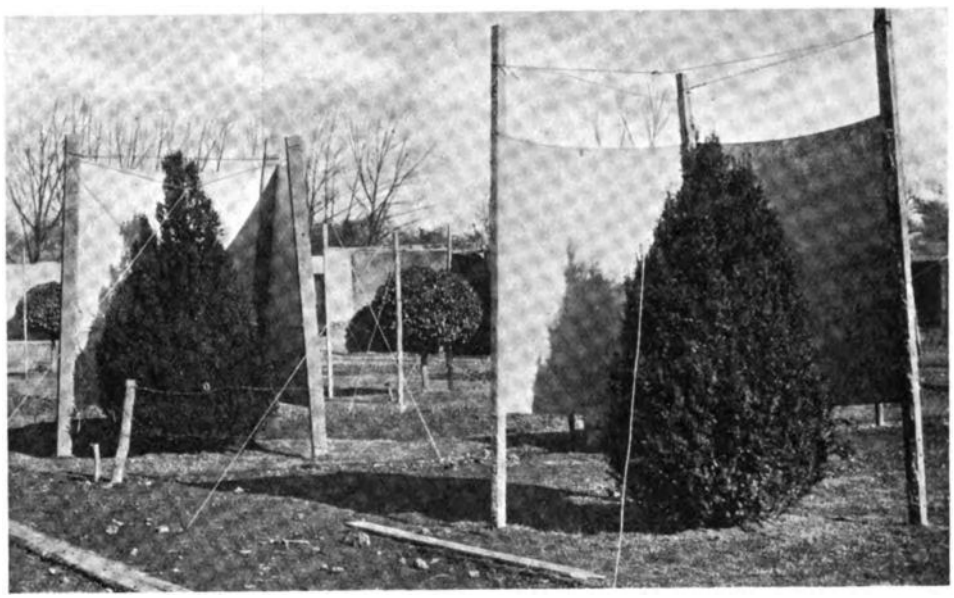
The Forestry Commission exhibit is taking the form of a village hall, a house and pavilion, built of home-grown timber, containing all manner of wooden articles manufactured in the country. All the various woods will be represented—Scots pine, larch and the English hard woods, showing their varied uses. The gardens surrounding the buildings will be laid out as nurseries in which young trees will be exhibited by Scottish nurserymen famed for their raising of young conifers. This Forestry section should prove of great value to the visitor in the great question of housing and lack of building materials, and will indicate the part which forestry can play in solving the problem.

On walking up the main avenue between the Palace of Engineering and the Palace of Industries one reaches an ornamental lake which is crossed by many small stone bridges. The north side of the lake is bordered with boxes containing periwinkles climbing over them. Towards one end, shrubs of various kinds have been planted. On the south side and towards the west end a small, picturesque rock garden has been arranged. It really forms a striking picture. No attempt has been made to furnish a covering of rare alpines to the rocks, but their absence is not noted, as the whole is clothed with dwarf shrubs and ericas, while hardy bulbs have been planted between the heaths which, on blooming, will lend a distinctive note to the rest of the colour scheme.

On the other side of the bridge will be found a grassy bank with rhododendrons, poplars, chestnuts, limes, and Picea pungens var. glauca, most of which are transplanted specimens. Truly a great feat. In summer such a bank will present a handsome appearance. A small island is to be found in this part of the lake with, as a background, a few tall handsome Lombardy poplars. To the left there is a small clump of Scots pines (also transplanted), their dark glaucous foliage lending a realistic touch to the picture. Bulbs have been planted indiscriminately along the southern borders of the lake. Already they are peeping above the ground and if the weather clerk is favourable one will witness the yellow of the daffodils in harmony with the varying hues and tints of the tulips, hyacinths and irises. When the bulb season is over, small garden shrubs and herbaceous annuals will be ready for transplanting—from a specially prepared nursery at Wembley, where at present they are being potted on—to their new home, to maintain the seasons in this Exhibition of exhibitions.



A GRASSY BANK WITH TRANSPLANTED SPECIMENS OF POPLARS, LIMES, AND CHESTNUTS.



A NOVEL METHOD OF PROTECTION AGAINST WIND, EMPLOYING CANVAS SCREENS.

ANEMONES

BY THE LATE MAURICE HEWLETT.

WINDFLOWERS ARE AMONG THE MOST CHARMING OF SPRING BLOSSOMS. THEY ARE FOUND IN THE WOODS OF ALMOST EVERY COUNTRY IN EUROPE; PERHAPS A BETTER NAME WOULD BE "WOODFLOWERS."

Anemones, which droop their eyes
Earthward before they dare arise
To flush the border, . . .

says the poet, and says truly, for I believe there is no exception to his general statement. The point is really one in the argument between the gardeners and the botanists, as to whether you are to reckon hepaticas as anemones. I shall come to that presently, and here will only point out that hepaticas do *not* droop their eyes—or hang their heads, as I should prefer to say. Let that be remembered when the scientist tries, as he is so fond of doing, to browbeat the mild Arcadian. Except for that remark I do not call to mind that the poets have sung about the windflowers. None of them has likened his young woman to a windflower. Meleager, indeed, when he is paying a compliment to his Zenophile, pointedly leaves it out.

ONE OF THE FINEST ANEMONES; THE CLEAR CUT ST[illegible] OF APENNINA.

Now bloom white violets, now the daffodils
That love the rain, now lilies of the hills,

he begins; and what lilies those could have been unless they were lilies of the valley (which sounds absurd), I do not know. But how could he talk about spring flowers in his country and leave anemones out? It is true, he was a Syrian; but politics do not interest anemones. No one is to tell me that Asia Minor is without Anemone fulgens.

Fulgens is the typical Greek anemone, anyhow, as coronaria always seems to me specifically Italian. It is a wonder of the woodlands—as of those between Olympia and Megalopolis, or of the yet denser brakes about Tatoi, where the late Constantine used to retire and meditate statecraft. Blanda, the starry purple flower of eighteen points is commoner in the open. Nothing more beautiful than the flush of these things under the light green veil of the early year can be imagined. The gardener in England who can compass anything like it is in a good way. Luckily it is easy, for these are kindly plants, seed freely, flower in their first year and are not so affected by climate as to change their habits to suit our calendar. Do not grow them in woods if you want them early. Our woods, *in quella parte del giovinetto anno*, are both cold and wet. Put them in the open, in light soil sloping to the south, and you will have as many as you want. One thing I have noticed about them is that in England fulgens is constant to its colour, whereas in Greece there are albinos, pure white and very beautiful, with black stamens. The pairing of those with the staple has produced a pink fulgens of great attractions. I have imported it, but it has not spread, and the seed of it comes up scarlet. Blanda has no sports, and is so proliferous that, if it is much grown in soils that suit it, very probably it will become a naturalised British subject. Here it is a weed.

Our own pair of windflowers is not nearly so easy to deal with as those two Ægean tourists. Nemorosa will only grow happily in woods, and even there does not readily transplant. Pulsatilla is subject to winter rot, as anything which lies out at nights in a fur coat must expect to be, and it reacts immediately and adversely to a rich soil. Now, nemorosa grows in the fields in Germany, even in water meadows; Pulsatilla in Switzerland will stand any amount of snow. But the snow in Switzerland is as dry as salt, and no flower objects to a flood when it is beginning to grow. The enemy in England is wet at the slack time. The best way to treat Pulsatilla is to grow it on a steep slope, for that is how it grows itself.

Talking of nemorosa, there is a harebell blue variety of it which I have seen, but never had, and, of course, the yellow ranunculoides, to be met with in Switzerland, though it is not a widespread plant. I found a broad patch of it under some trees on the edge of Lake Lugano; a clear buttercup yellow, not a dirty white. I do not call it an exciting plant, all the same, and am perfectly happy without it, and to know it is the only true yellow anemone that exists.

No offence, I hope, to the great sulphur anemone of the Alps, a noble windflower, indeed. I know few things more exhilarating than to round a bluff and find a host of it in stately dance. And I know few things less so than to try to dig it up. I have devoted some hours to the pursuit, notably after a night spent at Simplon Dorf. I rose early and toiled till breakfast. I had an inefficient trowel, bought in Florence, and an alpenstock, and with them excavated some two feet of Simplon. At that depth the root of the sulphur anemone was of the thickness of a reasonable rattlesnake, and ran like the *coda* of a sonata, strongly, and, apparently, for ever. Something had to give, and it was the anemone. I coiled up what I had, brought it back with me in a knapsack, and made a home for it among my poor rocks. Nothing to speak of happened for

Digitized by Google

two years, except that it let me know that it lived. Then came a spring and a miracle. The sulphur anemone burgeoned; that is the only word for what it did. Since then it has never failed, though more than once the rocks have been rent asunder. In what goes on underground, this anemone is a tree.

I do not forget—am not likely to forget—coronaria, which in its (I must own) somewhat sophisticated form of Anemones de Caen is the glory of my blood and state in the little hanging garden I now possess. I own, it seems, the exact spot it likes. It is thoroughly at home, and proves it by flowering practically all the year round. In the dog days, I do not say. But who cares what happens in August? Except for that waste month—the only one in the almanac with nothing distinctive to report—I believe I have hardly failed of a handful of coronaria. Since Christmas I have not failed of a bowlful, and in this month of April, 1923, it is out in a horde. Wonderful things they are: 9ins. high, 4ins. across, with a palette ranging from white through the pinks to red and crimson, through the lilacs to violet and the purple of night. There are few better garden flowers. Untidy? Yes, they need care. Too free with their seed? They cannot be for me. I am open to the flattery of a flower's confidence, as, also, to that of a woman's. Another thing to its credit is its attraction for bees, with the range of tint and tinge which that involves. Your whites will be flushed with auroral rose or clouded with violet; you will have flecks and splashes of sudden colour, the basal ring of white—whence comes its cognomen, annulata—will be sometimes invaded. Even the black centre with its stamens is not constant. I have one with a pale green base and stamens of yellow. With these fine things fulgens goes usefully and happily. Coronaria has no such vermilion. A bank of the two together growing in the sun can be seen half a mile away, and will not look like scarlet geranium if there is a judicious admixture. To qualify that dreadful sophistication called "St. Brigid" I shall serve myself of W. S. Gilbert's useful locution; "Nobody," he said, "thinks more highly of So-and-So than I do; and *I* think he's a little beast."

A FINE TUFT OF ANEMONE PULSATILLA.

Apennina, I think, wants a mountain. I should like to try it in some favoured ghyll in Cumberland; and some day I will. I have it on a lawn, and have had it for many years. There is no less, but no more, than there ever was. It does not seed. The two colours, china blue and white, are delicious in partnership, though the blue is not so good as that of blanda, and the white not quite so white as nemorosa's.

And what am I to say of hepaticas, and how *écraser* the botanists? Who am I to deny them with my reason—entirely satisfactory to myself—that the *feeling* of the two flowers is distinct and separable? What does an anemone imply? A spring woodland on a mountain slope. What an hepatica? A wet cleft in a rock, sodden last year's leaves, ragged moss, pockmarked crust of snow—and out of them a pale star raying gold from blue. The anemone is gregarious, the hepatica solitary; the anemone is a spring flower, the hepatica a winter flower. And lastly, as a gardener, I say, the anemone can be moved and is often much the better of it; the hepatica should not be, and is always the worse. If you plant an hepatica root and leave it alone for fifty years, you will have something worth waiting for—a ring of it as big as a cart-wheel. I have not done it—but it has been done for me.

With all these distinctions, nevertheless, the two are intimately related, belonging as they do to the same Natural Order Ranunculacæ. They are both graceful flowers and pleasing to the eye and everyone should be happy indeed to see them appearing in the garden.

ANEMONE NEMOROSA BOSNIACA IN THE ROCK GARDEN, FORMING A PLEASING SIGHT IN EARLY SPRING.

TOMATO CULTURE

BY EDWIN BECKETT.

IN the year 1596, four varieties of edible tomatoes, or as they were more familiarly known in those days, "Love Apples," were brought to this country from South America. It is very doubtful whether their introducer ever dreamed of their becoming popular other than as pretty, ornamental fruiting plants. Indeed, for nearly three hundred years they had but little other use, and yet, in less than half a century, they have become so important an adjunct to the culinary list that they now claim a trade all to themselves, and even the enormous quantities grown annually in this country do not cope with the demand, and we have to import many from abroad. Yet it is possible, where there is a fair amount of glass, for them to be grown almost all the year round, in fact, by careful arrangement I have had no fewer than four crops of fruit from one house inside the space of twelve months. Modern sorts lend themselves very readily to this work, and are of robust constitution, far in advance of their antecedents.

A commencement should be made by sowing seed thinly early in January, in a light, sandy compost, and germination should take place in a temperature of from 50° to 55°. It is as well to warm the compost to this temperature before sowing. See that the seed pans are well drained, and only cover the seed lightly with a dusting of the finer particles of the compost. Once the seedlings are through, place them close up to the glass of the house to promote sturdy, healthy growth. The next step should be to prepare a light compost comprising mostly leaf-soil and sand, with a very small amount of light loam. This should be mixed and put into the house with the seedlings to warm up, and the young plants potted on, singly, into thumb pots, before the second leaves appear, inserting them right up to the seed leaves in the compost. Water well in at this stage with tepid water and place up close to the glass. The idea of conducting these operations in the same house is that by maintaining a level temperature, risk of check is precluded, and the aim at all stages should be to promote and continue steady, healthy growth, for, otherwise, results will not come up to expectations.

Stage number three calls for potting on into 60 pots, under similar conditions, when the thumb pots are well filled with roots, and a slightly heavier (more loamy) compost should be employed, and transference into 48-sized pots should later take place, as increased root formation demands it, again with a little heavier compost, taking care now to employ a thin stick to which to tie the plant for support.

Care should be taken here to note that soil in the pots should never be saturated, nor the atmosphere of the house be too moist and stagnant, at any period, for these are the principal reasons for disease and lack of fruiting. When the pots are again full of roots, the final potting on should be done, using either 8in. or 10in. pots, or suitable sized boxes, and see that they are well drained. Employ for the work a compost of three parts fibrous loam, one part decayed leaf soil (as a substitute for this spent mushroom bed manure may be used) and, added to these, sufficient coarse sand to keep the whole thoroughly porous and open. Do not sift this mixture too finely, and make the plants very firm in it when planting. When potting it is only necessary to employ, for a start, a sufficiency of soil to cover the roots, and this should not be too rich in character. The plants should then be grown either supported to stakes or trained up the wires of the house, but in all cases as close to the glass as is possible. Feeding will not be required until fruit has set, and the top-dressing required from time to time, until the setting takes place, should consist of similar compost, added as root growth is apparent.

To assist fruit to set, the plants should be gently tapped two or three times a day when in flower, to spread the pollen. Failure to set is generally to be accounted for by the plants having received too much moisture, either at the roots, or through the atmosphere, during their young growing period, and through this error having formed sappy, rank, useless growth; yet another cause in this direction is inefficient or defective ventilation. When fruit commences to set, then richer compost may be added as a top-dressing, and after a quantity is apparent, use a reliable fertiliser as a dressing. Feeding with diluted liquid farmyard manure will be very beneficial, the strength of the liquid being increased with the quantity of fruit setting. When fruit commences to colour remove it from the plants in order to relieve their burden and so help them to perfect the remainder of the crop. Fruit removed will ripen well off the plant, if placed in a warm, dry room.

For the maintenance of supplies through summer and autumn and even beyond, three or four sowings at intervals during the spring will be necessary, and the cultural directions are the same as the foregoing. For winter work, sow in August, and use every effort to grow the plants as sturdily and healthily as possible in order that they may have efficient constitutions to perfect themselves under the more trying conditions of the shorter days and longer nights they have to go through. The house is an important factor for winter work, for it must be well and efficiently heated, the ventilation system good and in proper working order, and the glazing in perfect condition to admit every particle of light possible during the short days. Undoubtedly the best form of structure to cover these points is a full-span house. The final shift of the plants should be into pots rather than boxes, and a temperature of 55° to 65°, maintained. Careful and controlled ventilation should be allowed whenever weather conditions permit. Assist the setting of fruit by hand fertilisation with a camel-hair brush or a rabbit's tail on a short stick.

Fine crops may be grown during the summer in frames on a mild hot-bed; the plants being trained as close to the glass as possible, and ventilation, feeding, etc., carefully attended to. The plants should be placed in their pots at the front or shallow part of the frame for starting them on their career. This method may also be adopted, with profit, in portable frames, even where a hot-bed is not available.

As an open air crop the tomato is, at best, a very precarious one, though against a good, sunny, southern wall they are generally fairly successful in greater or lesser degree according to the season experienced. Raise the plants from a sowing made early in March, dealing with them in the same way as detailed above until the time arrives when careful hardening off should be undertaken whereby the plants may be ready for planting in the open at the end of May. Plant out at the foot of the wall, about 18ins. to 20ins. apart, secure to stout stakes, and only allow three or four trusses of fruit to set, after which pinch out the points of the plant, and at all times remove any side growths as they appear. If there is no wall and the plants have to be grown in the open, select the most sheltered sunny site, dig it well, but do not manure it, as this is fatal owing to the promotion of sappy growth. Allow 4ft. from plant to plant and 6ft. between the rows, and securely tie the plants to reliable stakes to prevent damage by heavy wind; also only permit sufficient fruit to set as will mature properly. In both cases remove fruit as it colours. Water plants in the open freely if weather conditions are dry, mulching slightly to assist this, but if the weather is wet and sunless, it is as well to shorten back the leaves to about half their length so as to aid the plant to perfect the fruit.

Pests are a trouble, but the worst of all under glass is the White or Snowy Fly, and immediately it is seen it should be tackled at once with a reliable fumigator, using this several times at intervals, so as to destroy the various generations of the pest that are in different stages of progress at the same time. This enemy attacks and destroys the foliage rapidly and thus prevents the plant ever being likely to fulfil its function of fruit production.

Fungus pests are mostly the result of too much moisture and inefficient ventilation, and affected parts should be removed from the plants and burned, and the plants dusted with black sulphur to prevent spread, and at the same time take the proper steps to remedy the cause of the ill.

A few words in conclusion will suffice to note a selection of varieties that may be relied upon for their utility, flavour and appearance for general work. Make a point to obtain the seed from a reliable source. For the early and main supplies under glass the following red varieties may be recommended: Comet, Kondine Red and Sunrise; while most distinct and

Digitized by Google

novel in appearance, but to my mind one of the very best flavoured varieties is Peachblow. Of the yellow varieties for similar use, the best are probably Golden Perfection, Golden Sunrise (the yellow form of the red variety) and Sunbeam. Prejudice, I know, still exists against yellow varieties, but there is no question that for quality and flavour they are the equals of the reds, and will at times surpass them. For winter work, as mentioned earlier in these notes, I would recommend Winter Beauty, a variety which is especially fitted for this work, as its name denotes; while Sunrise is also excellent. Again, for out-of-doors growing, Sunrise scores, and should be employed for this work, and if variety is required, then select a good type of this class of tomato. A word or two as to new varieties before finishing. If it is desired to grow these when they are introduced, make a trial growing first, before using largely, to make sure that they will succeed well under your own particular conditions, as success or failure may be greatly influenced by environment.

TULIPS AND ORCHIDS AT VINCENT SQUARE

ALTHOUGH officially it was to be principally an orchid show at the Royal Horticultural Society's Hall, Westminster, on March 11th and 12th, it was really a spring flower show and the fine spring-like weather induced a very large attendance. The outstanding floral exhibit was a magnificent collection of early tulips, arranged by Messrs. Sutton and Sons, in the form of a large flower carpet in which they displayed a large number of brilliant-coloured tulips in very many varieties. This gold medal exhibit illustrated sound, well ripened bulbs of first quality and expert cultivation.

Brilliant colour was also provided by the large quantity of splendid greenhouse cyclamens shown by Mr. J. W. Forsyth. The silver-leaved varieties were very prominent and these bore better flowers and in larger quantity than is usual. The form of the flowers, too, was good. Scarlet Queen and a salmon coloured variety of this type are excellent examples. Mauve Queen and Simplicity, also of mauve colouring, were very charming.

Forced azaleas, especially indica and Japanese varieties, were plentifully shown. Mr. L. R. Russell associated them with Begonia manicata, Clematis indivisa lobata, bearing trails of starry, white flowers and the weird Tillandsia Zahnii, a bromeliad which has a cluster of yellow flowers surmounting a bright reddish stem. Messrs. R. and G. Cuthbert had a collection of Azalea indica varieties of useful sizes.

In a little rock garden of pleasant design Messrs. Wm. Cutbush and Sons displayed dwarf bushes of Japanese varieties of azaleas bearing countless numbers of small salmon tinted flowers. There were several other attractive plants on Messrs. Cutbush's stand, among them Andromeda polifolia, with masses of white bells; this species should be grown more in our gardens. Fine sprays of Cydonia japonica alba were also to be seen on this stand. Messrs. J. Cheal and Sons also had a small rock garden.

Azaleas of good types with taller bushes of double-flowered cherries, white brooms and other shrubs, with seasonal alpines, made an attractive display in the group of Messrs. Wallace and Co. Tall wistarias rose above massed azaleas, interspersed with palms in the collection of Messrs. John Peed and Sons.

The new white lilac was included by Mr. F. G. Wood in his exhibit, which also contained carpets of double lilac primroses and a large-flowered single blue variety, while several especially good lilacs, in pots, were set out by Mr. Endtoz.

In a collection of well grown pot roses, Mr. E. J. Hicks had a large centre stand of Climbing Lady Hillingdon, flanked by Columbia and Queen of the Belgians, the last named is a beautiful single variety of large size and lovely soft pink colouring.

Messrs. Stuart Low and Co. showed good hippeastrums with Acacia Baileyana, and among their carnations included

A VERY FINE LILAC, JAN VAN TOL.

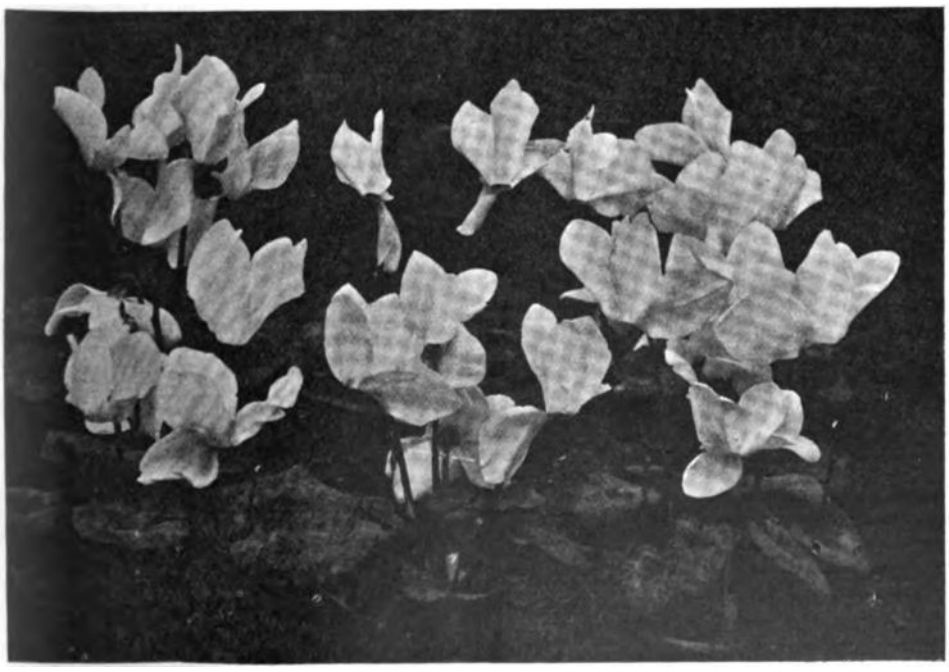
Sir Philip Sassoon, a new perpetual-flowering variety of good form and deep crimson colouring. Nearby they had a large vase of the rosy-cerise Reginald Cory. Messrs. Allwood Bros. had a large collection of their new perpetual border varieties of great merit and a selection of the ever-blooming Allwoodii hybrids. Messrs. Keith Luxford and Co. and Mr. C. Englemann also staged good carnations.

The first large collection of narcissi for the season was displayed by Messrs. J. R. Pearson and Sons, and this was an excellent group composed chiefly of such admirable large trumpet varieties as King Alfred, Lowdham Beauty, Florence Pearson and Cleopatra, with the smaller and more delicate Capella. The Poeticus and Barrii types were also represented by very good blooms. Messrs. R. H. Bath, Limited, again showed bulbs in fibre.

At the other end of the hall Messrs. Carter and Co., Limited, had a large collection of daffodils in pots, the chief varieties were King Alfred, Victoria, Lucifer and Seagull.

Messrs. Barr and Sons showed the smaller daffodil species with chionodoxas, Christmas roses, and well flowered bushes of forsythia. Messrs. Skelton and Kirby also showed forsythias and included some heaths and alpines.

Alpines and border flowers were shown by Messrs. Carter Page and Co., Messrs. Pulham Bros., Messrs. Bakers, Limited,



CYCLAMEN GIANT WHITE WONDER STRAIN WHICH GAINED AN AWARD OF MERIT.

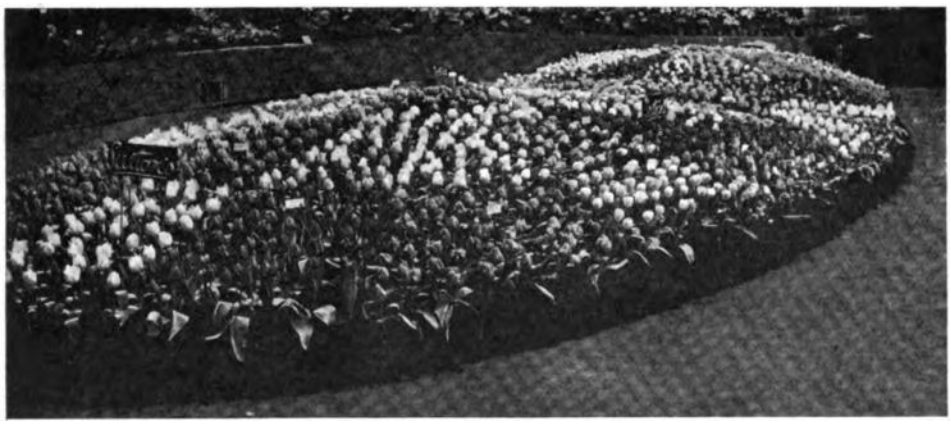
Digitized by Google

who included the golden flowers of Ranunculus montanus and Primula capitata; Mr. M. Prichard had a bright patch of Anemone fulgens and saxifrages in a low rock garden; Messrs. Waterer, Sons and Crisp, Messrs. Maxwell and Beale and Messrs. R. Tucker and Sons, displayed alpines. Such saxifragas as Irvingi, Burseriana varieties, kewensis, oppositifolia splendens, and dalmatica were shown in fine masses of flower. The Orpington Nurseries Co., had a sober but valuable collection of conifers and other shrubs suitable for the rock garden.

Sir Arthur Vivian, K.C.B., sent from his garden at Bosahan, Cornwall, many sprays of half hardy shrubs which excited a good deal of interest. The collection included flowering examples of Magnolia Campbelli, Berberis Bealei, with fragrant flowers, Clematis Armandi, Clianthus puniceus, bearing its curious large pear-shaped flowers, Azara microphylla, Nuttallia cerasiformis and richly coloured trusses of Rhododendron barbatum.

Sweet violets were shown by the Misses Allen Brown and Mr. B. Pinney, the former included especially good bunches of yellow and pink coloured varieties.

Messrs. G. Bunyard and Co. continued their exhibits of seasonal apples and on the present occasion staged dishes of Cobham, Sturmer Pippin, Calville Rouge, Calville Malingre, Claygate Pearmain, Rosemary Russet and King of Tomkins County. Messrs. Shearns, Limited, had another of their fascinating "shop-window" collections of fruits.



A MAGNIFICENT FLOWER CARPET OF TULIPS EXHIBITED BY MESSRS. SUTTON & SONS.

NEW AND RARE PLANTS.

CROCUS ÆRIUS VAR. CELESTE.—A rather short-stemmed variety which produces large, rounded flowers with milky-white centres, flushed with blush lilac towards the tips of the segments and on the exteriors. The filaments are orange coloured. Award of merit. Shown by Mr. G. Reuthe.

CROCUS TOMASINIANUS PICTUS.—This is rather a thin bloom with pointed tips to the segments which are heavily flushed with purple. The filaments are deep yellow in colour. Award of merit. Shown by Mr. E. A. Bowles.

CYCLAMEN GIANT WHITE WONDER.—The plant which received the award was of excellent type and very floriferous, but those in the group of greenhouse varieties were not so good, though the flowers were of large size and freely produced. The blooms were sprawly and had lost the fascination of the real cyclamen form. There is a distinct need for a really good white strain which produces blooms of good shape and it would seem that it could be evolved from the variety under notice. Award of merit. Shown by Mr. J. W. Forsyth.

SYRINGA JAN VAN TOL.—This is a magnificent single white lilac. The trusses were large, erect and shapely, and the individual, pure white flowers were well disposed. Award of merit. Shown by Mr. F. G. Wood.

VIOLA ODORATA ROSEA.—Often the pinkish coloured violets are not at all fragrant, but this is a welcome exception as the medium-sized blooms are deliciously fragrant. A couple of pot plants were shown and these displayed fair floriferousness, but the flower stems were a trifle shorter than most would like, though probably under frame culture the stalks would be longer. Award of merit. Shown by Mr. C. Duruz.

ORCHIDS.

AWARDS OF MERIT.

CYMBIDIUM PRESIDENT WILSON WESTONBIRT VAR.—The spike bore ten large flowers, bronze tinted with reddish shading; the cream-coloured lip has a dark crimon blotch on the apical area.

CYMBIDIUM MACAW.—A pleasing flower of brownish crimson tints, the lip bearing a V-shaped blotch of deep crimson.

CYMBIDIUM REDSTART VAR. ROSY GEM.—A beautiful flower, rose coloured, the broad lip white and speckled with rose.

CYMBIDIUM LINNET VAR. OLIVE.—This plant carried a spike of nine large flowers, in colour bright olive green, the lip slightly spotted.

CYMBIDIUM RING DOVE VAR. RUBY.—A charming hybrid of rose pink colour, the expansive labellum boldly marked with large spots and a median line of dark crimson.

The above five cymbidiums were exhibited by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt (gardener, Mr. H. G. Alexander).

CYMBIDIUM ALEXANDERI VAR. PRINCESS.—A pretty flower of uniform rose-pink colour, the labellum having a crimson apex. From Messrs. J. and A. McBean, Cooksbridge.

CYMBIDIUM CERES VAR. RUBRUM.—One of the best forms of this elegant hybrid. Flowers of deep reddish rose colour. From Messrs. Sander, St. Albans.

ODONTIODA THE TORCH.—A fine result in which the flowers are above average size, the segments effectively blotched with crimson-rose. From Messrs. Sanders, St. Albans.

Gold medals were awarded to Lieut.-Colonel Sir George Holford, K.C.V.O., and to Messrs. Sanders for fine groups of cymbidiums, also to Sir Jeremiah Colman, Bt., for an excellent exhibit of Lycaste Skinneri and other choice species.

BUDDLEIA COLVILEI

THOSE of us who have the good fortune to possess Sir Herbert Maxwell's latest flower book, "Flowers: A Garden Note Book," look many times and oft at the illustrations in colour, reproductions of paintings by the gifted author. One which is of high interest to many is that of Buddleia Colvilei shown there. Sir Herbert speaks of it as 20ft. high on the walls of his laundry at Monreith, and his only regret seems to be that it does not flower with more freedom there. It is indeed a magnificent climber or wall shrub, far surpassing in the size and beauty of its flowers any other Buddleia in cultivation. That it does not flower everywhere is generally the fault of its environment. It is one of the shrubs which flowers on the wood of the former year, and this is sometimes so injured by frosts in winter that the flowers are not produced. It seems, also, to take a few years to attain flowering size. There are a few gardens in the south-west of Scotland where it does not suffer from frost every year, and with a mild winter the delight of its long, drooping racemes of rose flowers may be anticipated. The Monreith plant is a very fine one. The first time I saw B. Colvilei in bloom was in the garden of the late Mr. W. D. Robinson-Douglas of Orchardton, Kirkcudbrightshire. It was some time before B. Colvilei bloomed with him, but I had the great joy of seeing it that season—now a good many years ago—and it struck one as among the finest of flowering shrubs. The same plant, which was on a south wall, flowered annually for a good while until a severe, long-standing frost one spring cut it badly back so that it did not bloom again for a year or two. Thinking it was not likely to do any more good after being cut back another plant was procured, but the old one revived and in due course seemed little the worse of its having been crippled for a time. The claret-coloured variety mentioned by Sir Herbert in the above work is certainly not to be placed on the same plane as the one with the lovely rose flowers.

S. ARNOTT.

FORTHCOMING EVENTS.

March 25.—Royal Horticultural Society's Fortnightly Meeting (two days). Masters' Memorial Lecture on the first day at 4 p.m. by Professor A. C. Seward, M.A., F.R.S., on "Plants as Evidence of Climatic Changes."

March 27.—British Carnation Society's Exhibition, to be held at the Royal Horticultural Society's Hall.

FRUIT-GROWING IN SMALL GARDENS.—V

BY RONALD G. HATTON, M.A.,
OF THE EAST MALLING RESEARCH STATION.

THE CONTROL OF DISEASES AND PESTS.

As to controlling the diseases and pests in your small garden, I will say straight out that, if you are taking your fruit-growing seriously, you must be prepared with some simple sort of spraying apparatus.

Do not be satisfied with the syringe that cleans the windows. A syringe, by all means, but one with a fine nozzle that will break up your spray and distribute it in a fine mist, underneath the leaves, on top, into the unopened truss, into the eye of the apple or wherever it may be needed. For several years I have sprayed quite successfully my growing cordons, and young gooseberries and currants with a simple garden syringe. If you have big, old trees in your garden, or your cordons are maturely developed, you may want to invest in a small knapsack sprayer..

I do not want to alarm people, but I want to make it clear that fruit trees and bushes are like human beings, some constitutionally strong, some weak. Often the choicest are in the latter class. Sometimes there may be an epidemic of disease, sometimes there may be a clean year, but if you let your fruits go under to the epidemic, it will almost certainly lose you good fruit for several succeeding years.

Now, I do not suggest a whole series of sprayings and a number of sprays, but an essential annual routine on your young trees should be followed. Once in three years they would benefit, just as the young leaves are bursting and before blossom opens, by a good covering lime-sulphur spray. This is a general cleanser, a tonic and, besides, helps to keep your apples clear of spot and crack, your gooseberries free from mildew, and your black currants free from "big bud." On apples liable to spot, on gooseberries liable to mildew, on black currants, and on any wall peach liable to leaf-curl I should make this an annual routine. The wash is non-poisonous, though it may scorch vegetable leaves. This will probably be about the first week in April, and the ground between your trees could then be clear of vegetable crops. Then, I should watch carefully for signs of young caterpillars and for the first mother green-fly, before blossom opens. If I saw any signs, I should be ready with a wash, preferably containing soft soap and nicotine (or any other harmless and effective insecticide), and this would be at my elbow until I had safely passed the season of the rosy aphids. Always spray before your leaves are curled. It is too late once they are curled. Nicotine is a vegetable poison and will do no hurt to other plants. As for harming individuals, I should certainly not care to eat lettuce, for instance, on which the spray had drifted, unless a good rain had supervened. But I believe this to be the safest insect wash for the garden.

Spraying nowadays has been made comparatively simple for the amateur. There is no trouble in mixing up various ingredients. A small tin of a proprietary lime sulphur or soap and nicotine, with full directions as to use, will supply almost all your needs. Only, remember that no spray can possibly cure everything. It has no miraculous power, it is effective just in so far as you hit your object at the right time in the right place, just in so far as you cover your leaves, shoots or fruit effectively. The cleaner you keep your garden, walls, fences, and trees, the less rubbish you have about, the less likely will you be to have epidemics of pests which find a ready harbour in such places.

MANURING.

Finally, remember that heavy manuring will cause too much wood growth for your top fruits, but that if you intercrop these with vegetables and starve the ground, you cannot hope to get good crops of either. Your raspberries, gooseberries, black currants and strawberries will always respond to generous treatment and, when you cannot get good stable manures, you need not be beaten. It is so simple to-day for the amateur to obtain the smallest quantities of the meat and bone meals, the rape dusts and fish meals that the commercial grower uses so much. They are so readily handled and easily sown. If the garden is in general good heart, it will almost certainly be good enough—if not too good—for your top fruits. If the ground runs together or dries out too quickly, you can improve it by digging in all the available green refuse matter or a crop such as mustard, when it is yet not too high. If the home has any refuse, such as small rag bits from the old piece drawer, any old spent feathers after the hen is plucked or the cushion discarded, do not forget what a high manurial value these things have in the garden and how the roots of your fruit trees will find them out.

In conclusion, may I refer you to helpful leaflets for the amateur such as those issued by the Ministry of Agriculture, on the "Control of Pests of Fruit Trees in Gardens and Small Orchards (Food Production Leaflet No. 39) and "Picking and Storing of Apples and Pears Grown by Small Cultivators" (Leaflet No. 283). After you have grown the fruit, you may easily spoil it by gathering too soon and by bad storage. Do not be in too great a hurry, favour rather the cool dark cellar than the warm dry attic. Fruit-growing in the small garden works in with the general routine of the home, it affords a ceaseless source of interest, and, if properly managed, a constant supply of fruits for the table. It will give you the appetite for still more. That natural magnetism of the apple tree for the boy really only expresess an hygienic necessity.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Plants for a Sloping Bank (M. B. T.).—The following kinds of plants are suitable for such a bank. They will spread and help to keep the soil in position. Achillea umbellata, Ajuga reptans, Antennaria tomentosa, Cerastium tomentosa, Saxifragas, Sedums, Sempervivums, Anemone japonica, Pinks, Alyssum saxatile, Montbretias, hardy Fuchsias, Euonymus radicans, Thyme and London Pride (Saxifraga umbrosa). Everlasting sweet peas are also suitable if allowed to spread on the bank without stakes. Periwinkles are charming for the purpose.

GREENHOUSE.

Climbers for Cool Greenhouse ("Tun Wells.").—The following plants will be found excellent for a cool greenhouse: Clianthus puniceus and its var. alba, Cestrum aurantiacum, Clematis indivisa, Lapageria rosea and var. alba, Mandevilla suaveolens, Lonicera sempervirens, Plumbago capensis, Senecio macroglossus, Solanums jasminoides and Wendlandii. If our correspondent has ample space plant also Cobæa scandens variegata, Tacsonia Van Volxemii and Passifloras cœrulea and Constance Elliott. The list could be further augmented with Abutilons Golden Fleece, Boule de Niege and insignis, also Fuchsias.

TREES AND SHRUBS.

Plants for Peat Bed (C. L., Hants.).—The following peat-loving dwarf shrubs would be suitable for this position. Daboëcia polifolia varieties; Calluna vulgaris vars. Alportii, Serlei and flore pleno; Ericas carnea and var. alba, darleyensis, ciliaris, Tetralix and var. alba, vagans and var. alba, Mawiana, cinerea and St. Keverne; Dwarf Rhododendrons impeditum, intricatum, Williamsianum, hippophæoides, flavidum and racemosum; Bruckenthalia spiculifolia; Bryanthus empetriformis; Kalmia angustifolia and Ledum latifolium.

MISCELLANEOUS.

To Make a Hard, Smooth Path (Lady R. C.).—If the paths in our correspondent's garden are near to the trunks of the pine trees, tarred paths may prove injurious. If they are 10ft. to 15ft. away and the trees are large, harm would not be done. The tar should be boiled in the open air, then poured into the centre of a heap of sifted ashes, all thoroughly mixed and spread evenly 3ins. thick on the dry, prepared surface. Roll with a constantly wet roller after freely sprinkling sifted gravel on the surface. A path of this kind will remain hard and smooth for many years. Gravel and cement, mixed, spread and rolled also answers well, but does not last as long as the tar preparation.

Names of Plants.—J. H., I. of W.—1, Colletia cruciata; 2, Cupressus Lawsoniana; 3, C. L. var. aurea; 4, Thuya dolabrata.

CORRESPONDENCE

PEONIES.

I WAS very interested in Mrs. Harding's article (page 119) on peonies to find mention of "pie nanny" as an old name for these herbaceous plants. Near to Lancaster, at Halton in the Lune Valley, is a place not much more than a cottage called Peony Hall, and a Scotchman who resided in Lancaster persisted in calling this place "Pie Nanny" Hall, much to my mystification. Evidently this is a Scottish term. Mrs. Harding must surely have struck a rock gardening clique when she mentions being informed that an Englishman could not raise his eyes from his rock garden. I should class several subjects as taking precedence.—M. H.

VEGETABLE PLANTS—RABBIT-PROOF AND OTHERWISE.

HAVING read with much interest Sir Herbert Maxwell's useful article on "Rabbit-proof Plants" in your issue of March 1st (pages 127-128), it has occurred to me that some of your readers might be interested in a few notes of a similar kind concerning our ordinary garden vegetables. I am of course aware that rabbits have no business in a well ordered kitchen garden, but most of us know from sad experience that they do not always stand on etiquette and will, if they so desire, enter by the front gate, if necessary, to get a feed. The following notes are made from my own experiences as a gardener in four English counties (Wilts, Surrey, Bucks and Hunts).

Rabbit-proof Plants: Savoys, kales (all kinds except asparagus kale), spinach (generally), broad beans, shallots, pickling cabbages, parsnips, vegetable marrows, sage, mint, marjoram, thyme, horse-radish, turnips (generally) and seakale.

Otherwise (to be specially protected where necessary): cabbages (generally), cauliflowers, broccoli (including both purple and white sprouting), beetroot, carrots, leeks, onions, parsley, asparagus kale, lettuces, peas and kohl-rabi.

These lists might be amplified, but will probably suffice. Rabbits, too, appear to be very fond of young wallflower plants in some districts, and are very destructive through scratching (preparatory to making new burrows in the early breeding season) among flower borders and carpet plants, if these are not protected in good time in rabbit-infested districts.—E. A. SAUNDERS.

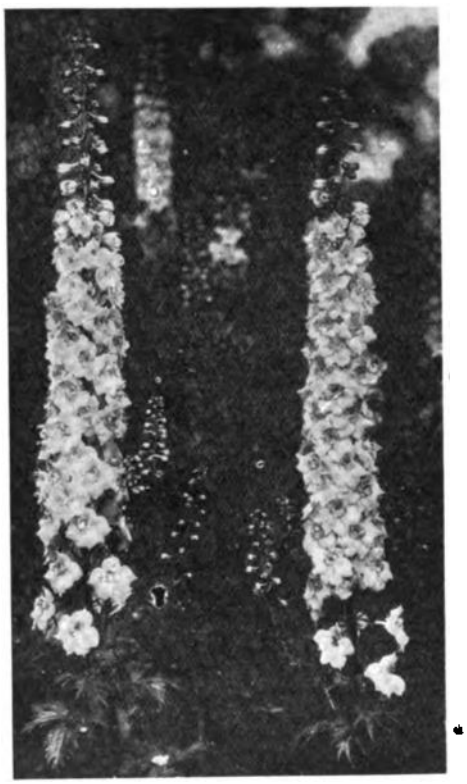
I HAVE read with much interest, as I always do, Sir Herbert's list of rabbit-proof plants in THE GARDEN of March 1st, but I am sadly afraid many of those mentioned, like a troublesome wife in the valley of Bong, would have but a short span of existence in my neighbourhood. The question of the rabbit's destructiveness really seems to come to this: it depends to a certain extent on the climatic and agricultural conditions of the district, what food the rodents have to depend on for their existence and, very possibly to a much more important extent, on the number of rabbits.

Where there are, say, three rabbits to the acre, the damage might be negligible; at thirty they would eat anything; and at three hundred per acre everything, in precisely the same manner as a starving man might struggle to exist on eating shoe leather if tossed in mid-ocean, but, placed under somewhat more favourable conditions, such as the dining-room of the Ritz Hotel, I think I can fairly safely hazard the opinion that that is not the form of diet he would be likely to select.

Apart from their destruction and wire netting, possibly one of the best preventives is Bentley's tree-protecting paint, manufactured by Joseph Bentley, Limited, of Barrow-on-Humber, which is excellent and will keep trees absolutely safe from the attacks of the rodents for at least seven months after application, and for young orchards it is all but indispensable where rabbits abound, but its application is rather difficult in the case of shrubs, etc., though this can be surmounted by surrounding them with old rope or something of that nature, attached to pins some 7ins. or 8ins. high, and smeared over with the mixture; but, most unfortunately, in localities liable to heavy snowfalls, the protection is lost just at the very time it is most urgently required.—FORMAKIN.

WHITE DELPHINIUMS.

IN March of last year you reproduced in THE GARDEN a photograph of a white delphinium which I raised from seed. THE



A WHITE SEEDLING OF EXCEPTIONAL MERIT.

GARDEN must have a very wide circulation for I have received interesting letters from New Zealand, Canada and other parts of the world, not the least interesting being one from a Quebec lady who has sent me photographs of her beautiful garden in that city. Last year several of my seedlings again proved to be white or cream-coloured varieties of quite exceptional merit, and I am now sending you a photograph of another one which perhaps you may be able to reproduce. The plant is wonderfully vigorous, the spike of bloom measuring rather more than 2ft. in length. It was raised, as the former was, from the seed of the blue variety known as Commandant Chapius, grown in close proximity to the white belladonna hybrid Moerheimi. This hybrid I have never known to seed, but it has occurred to me that its pollen fertilising the blue variety may possibly account for the number of white seedlings I have been fortunate in raising during the last two years.—W. C. BLAKEWAY.

DELPHINIUM AS A NAME.

I AM afraid no very conclusive answer will be forthcoming to Mr. Jacob's question (page 113) about the derivation of this name. In my classical library, which is fairly well furnished, I find no verification of the pretty American story which he quotes, of garlands of delphinium flowers being used in a procession to the temple of Apollo Delphinios. There certainly was a temple with this dedication at Athens, but little more than its bare name seems to be recorded. And I can find no corroboration of the assertion that blue was the favourite colour of the Greek deities, or of any one of them. Nor is it possible for anyone to know now that the supposed blue flowers of these garlands were "undoubtedly delphiniums." Hardly a flower named by classical writers, except the rose, the narcissus and, perhaps, the anemone can be positively identified. But the transatlantic Press is apt to invent where it does not know.

More than one species of delphinium (larkspur) are wild in Greece, and one at least was used medicinally, according to Dioscorides and other writers. But we cannot be sure whether delphinium was meant or aconite (monkshood), as they run into one another botanically and aconite is still used in medicine. In an enquiry into a plant-name it should always be remembered that sentimental or poetical derivations are unlikely to be true, especially of very ancient names. Thus, "heartsease" had at first no sentimental associations, but was a plant the decoction of which was supposed to give relief in cases of heart disease.

The "hood" of the monkshood, and the same part of the delphinium flower, especially in the bud, in shape might suggest the curved back of a dolphin, the Greek for which is *delphis*, and dolphins were, and are still, very common all round the Greek coasts; but to go a step farther back in etymology, and to jar upon our poetical notions, the root meaning in Greek of *delph* is undoubtedly "pig." The dolphin took his name from his resemblance to a pig; he is the "sea-pig," just as the porpoise, his near relative, bears a name that is a corruption and abbreviation of the Latin for "pig-fish"—porcus-piscus, porc-poisson, porpoise. And it is probable that the famous oracle-site of Delphi, despite its romantic associations, was originally simply "the spot where wild boars abounded." Similarly, "delphinium," if not so named from the dolphin-like (or possibly pig-like!) shape of its blossom, may have some other connection with wild boars or domestic pigs not now traceable—perhaps as pig-food or pig-poison (compare our "pig-nuts"). After all, it must be said that many plant names have come down, sometimes unrecognisably altered, from such remote antiquity that they belong to language-forms now extinct, and explanations can be only guesses. Scores of instances could be given. To take one only, what was the original meaning of "anemone"? Old writers connected it with the only Greek word they knew at all resembling it—*anemos*, wind. We copy them in our current name, "wind-flower"; but what have anemones to do with wind? Pliny says they are so called "because the flower only opens when the wind blows," which is absurd. Possibly the old Latin and Greek root *nem*, which means "wood," is embedded in the name, and the anemone should be called the "wood-flower," which is appropriate enough. But we do not *know*.—G. H. ENGLEHEART.

NOTES FROM CONTRIBUTORS

PERENNIAL CONVOLVULUS FOR THE ALPINE GARDEN.

ASSOCIATION with that terrible pest, the common bindweed, is apt to recoil somewhat unfairly on the whole family of convolvulus, whereby many—who know them not—are apt to exclude a series of extremely beautiful plants. Beautiful in their foliage, beautiful in their flowers and possessing that delightful charm of clothing and draping the face of large rocks and boulders with sheets of the said beautiful flower and foliage curtain.

Before entering upon any discussion of varieties, let us make it quite clear that real success is only to be achieved by special culture. As befits the aristocrat, they must be given suitable homes and conditions; failure is certain if you just tuck them in and leave the rest to chance. Natives of warmer and sunnier climes than ours, a warm sunny bank with a light dry sandy, chalky soil and a raised position must be provided and—where this is done—we can promise you that you will never regret the introduction of the choicer convolvulus.

Let the soil, then, consist of fibrous loam to which a generous addition of sharp coarse sand has been made, and be sure that this is deep enough and, in addition, that the pocket where planting is done is well drained at the bottom by a layer of stones or gravel some 3ins. thick. It is stagnant moisture in winter that causes death of the plants, and these somewhat elaborate preparations are your insurance on the life of the plants and their health and well-being.

The mallow bindweed, C. althæoides, may be used either as a climber for covering a low wall or just allowed to trail over the ground where its shoots have about 3ft. of space in which to run. The leaves are remarkable in that the lower ones on each stem are heart-shaped and a beautiful silvery hue, while the upper ones are deeply cut into narrow segments of the same shining hue. Flowers, which are rose, are produced in pairs in summer. Propagation by division.

The bryony-leaved bindweed (C. bryoniæfolius) again may be used as described for the preceding species, and has leaves which vary somewhat in shape, but are mostly heart-shaped and very hairy on both sides. The flowers are very large, deep rose or reddish in colour, produced singly in summer. Propagation by seed or division.

The Cantabrian bindweed (C. cantabricus) does not twine, but branches freely and grows upright to a height of 1ft. or more. Both stems and seed vessels are densely covered with white silky hairs. The flowers, which are produced in summer, are very numerous and borne on long leafy stalks varying in colour from pale pink to rose or flesh colour and silky on the outside.

The silvery bindweed (C. Cneorum) forms an ever-silver shrub 1ft. to 3ft. high. The leaves are small and of the colour described, while the rose pink flowers are produced in clusters on the ends of the branches during summer. Propagation by seeds or cuttings.

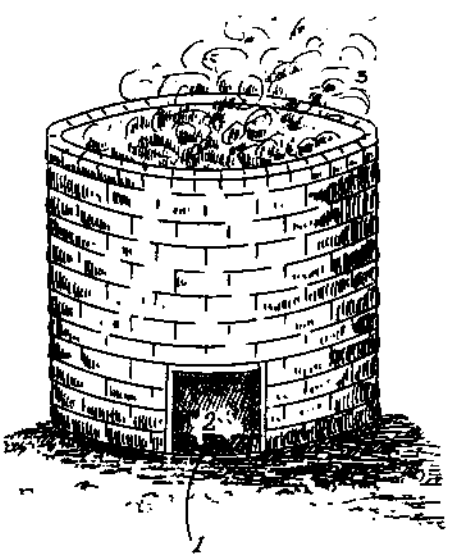
The pigmy bindweed (C. lineatus) is a charming diminutive, only 3ins. to 6ins. high, with very silky lance-shaped leaves. The flowers are rose coloured, generally in pairs and over 1in. across. This is the only member of the family that will live on a cold soil, thriving more or less on the stiffest clay, but even this flowers most freely on the lighter soils.

The blue rock bindweed (C. mauritanicus) introduces a change in colour, and these, although not large, are very freely produced. The habit of this is trailing and the stems so slender as to be almost thread-like, with round leaves that have to be examined very closely before the short white hairs, so conspicuous in other species, can be seen. You must provide a raised position for this, not only to allow for the trailing growth, but to make absolutely certain of the drainage. Propagation by division or cuttings.

The sea bind weed (C. soldanelloides) is splendid from the flowering point of view and also has the advantage that, beautiful as it is in the rock garden, one can grow it in the ordinary border and in ordinary soil. The habit is trailing, with roundish leaves which are rather fleshy. The flowers are pale red, very handsome and borne with great freedom during summer. Propagation by division.—H. W. CANNING-WRIGHT.

A USEFUL GARDEN REFUSE BURNER.

IN all gardens, refuse of various kinds accumulates rapidly, and, if left in heaps, it is not only unsightly but soon becomes offensive. There should not, however, be any waste of such refuse. If it is not convenient to burn the rubbish, the only alternative is to have all such carted away or treated with lime or salt and buried in the vegetable quarters. The cleanest way, however, is to burn all to ashes. The sketch shows a useful burner that would prove helpful in any garden, but especially in town and suburban gardens.



A USEFUL TYPE OF REFUSE BURNER

These structures may be of circular or square shape, built on the level ground or partly below it where the soil is naturally dry. Hard-burned or clinker bricks are the best; there is no need for many bricks to be left out to provide air passages in the sides when the burner is constructed as shown. A layer of loose bricks or stones should be placed to form a base and draught way, shown at No. 1. The lighting hole, No. 2, should have an iron frame, and, when the rubbish fills the receptacle, burn it when the smoke, No. 3, will blow away from a neighbouring dwelling-house, or the owners, so as to prevent a nuisance.

These rubbish bins of brick or stone will keep the contents dry as the latter are placed there from time to time, if a sheet of zinc is placed on the top, also the ashes, after burning, till they are cold and fit to store—a very important point. Furthermore, the zinc sheet can be used to regulate the burning of the rubbish by partly covering the top when the fire is well alight.—G. G.

DROPMORE IN EARLY SUMMER.

AS the days grow longer owners of cars turn their thoughts to expeditions from town for the day, and those who cannot motor or bicycle, think out walks. In June no better drive can be found than one of about twenty-five miles to Burnham Beeches and Dropmore. The Beeches are but a few miles from the garden and shrubberies of Dropmore. They can be reached either by the train from town to Taplow station (after all everyone does not own a car), three and a half miles distant and approaching by the road which leads from Taplow and Cleveden and so along the drive which passes wild bits of woodland and heath to the west of the house, or from East Burnham entering the Lodge close to Littleworth Common. The grounds are open on Mondays, Wednesdays and Saturdays from 11 to 5 and one is shown over them by one of the gardeners, after leaving the car or bicycle near the house. It is a good plan to enter by the Littleworth gate as Dropmore at the end of the eighteenth century was part of a gorse and heath covered common until bought by William Wyndham, Lord Grenville (1759-1834) in 1792, and one thus realises what his work was in planting and planning Dropmore, and how well exotic trees flourish in this country if managed with skill and care and if the soil is specially prepared for them.

Here we find spreading beeches and the elegant birch mixed with fine oak and elms, but rarer specimens are to be seen—cedars, the deodara extending its drooping branches high in the air, also pines of various kinds. Here and there an araucaria stands out with motionless stateliness against the sky. On the lawn is a Cedar of Lebanon which Lord Grenville planted in 1794, and throughout the many acres of grounds are to be seen pines which grew under his eye. Frost, his head gardener (who lived until 1887), when taking visitors round used to point out splendid trees which he gravely said he had once carried in his waistcoat pocket. The house, which was built by Lord Grenville, is hardly worthy of its beautiful surroundings.

No bit of copsewood was ever too small for Lord Grenville to take an interest in and his great understanding of landscape beauty is seen in what is known as "The Root Mount," which was built under his own supervision. One gradually climbs up to this ascent leading from shady walks of beech, honeysuckle and azaleas to a projection high above the trees, below one's feet are masses of rhododendrons, azaleas and a bush or two of scarlet camelias and beyond acres of green pasture land with here and there specially planted woods of beech, etc. In the distance a silver gleam curving in and out on the landscape denotes the Thames, with the towers of Windsor Castle standing high above it, and still further away on a fine clear day the outline of the Surrey hills can be seen. But the chief beauty of Dropmore in the early summer months is its multitude of azaleas and rhododendrons. Many people only know azaleas from seeing them grown in pots, or in small borders with specially prepared earth; here they grow in rampant and luxuriant bushes high above one's head, sheets of pale yellow, orange and flame colour. As one draws in deep breaths of their intoxicating perfume one wonders if Nature ever produced anything more beautiful. On the ground beneath and scattered far and wide are thousands of seedlings hastening to overtake their parents in growth. One wanders on and suddenly comes upon a lake where, hanging over the banks and reflected in its shimmering waters, are clumps of different coloured varieties of azaleas—EVELYN P. VENNING.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Potatoes.—The planting ot these will be fairly general, and it is always a good plan to get the main crop in by the middle of April, although I have occasionally set out tubers towards the end of May. The object of early planting is to allow lifting of the crop before the potato disease is prevalent. It is advisable to wait until the soil is in a suitable condition before planting. Clayey soils may still be wet and pasty, and therefore not ready; but light sandy soils are available at almost any time. Assuming that the tubers are sprouted, care should be taken when filling the holes or trench with soil or the young shoot will be broken. Plant the tubers several inches deep, and the rows should be from 2ft. to 2ft. 6ins. apart, according to the strength of the varieties chosen.

Spinach.—The summer variety of spinach may be sown in quantity between rows of peas or on any odd corner. If it is not required, it may be dug into the soil. The perpetual or spinach beet should certainly be grown wherever spinach is appreciated, because it is often in a thriving condition when the ordinary type fails, especially during a hot, dry period. Sow in lines 1ft. apart, and thin the seedlings to half that distance in the lines.

THE FLOWER GARDEN.

Mignonette.—Among annuals the sweet-scented mignonette occupies a high position, and it should find a place in every garden. It is easily grown, and may be obtained in various colours, such as yellow, white and red.

Eschscholtzias.—During the last few years, decided progress has been made with these charming flowers. Although it is usual to sow the seeds where the plants will flower, it is almost an impossibility with many of the new varieties, because the seeds are so few. In such cases it is best to sow in boxes containing light soil, and when the seedlings are large enough to handle, prick them off and finally transfer them to their flowering quarters. On no account should the seedlings become starved, as they rarely make fine plants after being checked.

FRUITS UNDER GLASS.

Early Peaches.—As a rule, peaches set plenty of fruit, and it is usually necessary to do a lot of thinning. Such work should be done gradually, and an interval of several days allowed between each thinning. First of all, remove the fruits that are on the undersides of the shoots; this is generally enough for the first thinning. Next time, they are further reduced to about three on each shoot, and these should be the best fruits and so placed that there is ample space for development. At the final thinning one fruit on each growth is sufficient. Over-cropping should always be avoided. Tie in the new shoots as needed. The trees should be well sprayed with tepid rain-water whenever the weather is bright, the best time being in the afternoon before the sun loses its power. The floors may be damped down twice daily, and a little air admitted through the top ventilators when the weather is favourable, viz., mild and sunny. A night temperature of 60° Fahr. should be maintained, with a rise of five or ten degrees during the day.

Keep the trees free from thrips and aphis, by occasionally vaporising the house. It is better to fumigate lightly two nights in succession, rather than overdo it by a single application.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Beetroot.—A few drills, 12ins. apart and about 2ins. deep, should be drawn out, and seed of the globe type sown, so that early roots may be obtained.

Cabbages.—Plants raised from autumn-sown seed should be set out now on well cultivated ground, in lines 18ins. apart and 15ins. between each plant in the line.

Carrots.—If one has found that the crop does well on a certain section of the garden, it should be grown annually on that part. No doubt the best roots are obtained when holes are made with a large dibber and filled with sand. This proves that carrots like a sandy soil. Although it is rather early to make the main sowing, part of the ground should be thoroughly raked and made fine, and drills drawn out 1in. or so deep and 15ins. apart, and the seed sown thinly. James' Scarlet Intermediate, Long Red Surrey and St. Valery are good and tried varieties.

Cauliflowers wintered in cold frames or on a sheltered border should be set out now in rows 18ins. apart and 15ins. between each plant in the rows; or they may be planted between the lines of first early potatoes on a south border. We have had seed of Early Snowball and Early London sown on the same date and planted out on the same day, and grown side by side; Snowball proved to be the earlier variety.

Cucumbers.—These plants may be grown in the melon house and trained to the wires, or they may be planted out in a hot frame.

Digging.—Borders from which various plants have been cleared should be manured and dug, and, after the ground is firmed and well raked, parsley and lettuce seedlings should be set in lines 12ins. apart and 6ins. between each plant in the lines.

Potatoes, Peas and Beans.—Continue to plant second early and late varieties, when the ground is in good order. Peas should be sown at intervals of ten or fourteen days, and broad beans as requirements demand.

THE FLOWER GARDEN.

Antirrhinums.—Frames from which partially hardy bedding plants have been cleared should be made ready and fresh soil added where required; also sprinkle a little sand over the surface soil and make smooth. On this prick out the antirrhinum seedlings 2ins. apart.

Bedding Plants.—Where the required numbers of plants have not yet been obtained, cuttings may still be inserted of ageratum, lobelia and musk.

Hollyhocks raised from seed sown last year and grown on in pots should be set out at the back of the borders. Enrich the soil with old manure or leaf-mould where the plants are to be grown.

Phlox Drummondii Sutton's Fireball.—This charming half-hardy annual is of dwarf habit, and seed should be sown rather thinly in boxes of fine soil and grown, after germination, in as hardy a way as possible. By this method no intermediate transplanting is necessary When the plants are sufficiently advanced have them transferred from the seed boxes to the borders. Care should be taken when lifting and planting.

Sweet Peas raised in long boxes early in February should now be sufficiently advanced and hardened to be set out on the prepared ground. Well water the roots before planting. After planting is completed support and protect the plants with small twiggy branches.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Impatiens Balsamina.—The double varieties of this plant have long been favourites for conservatory decoration, and by successional sowing may be had in flower over a long period. A start may be made now by sowing in an intermediate temperature. The seed should be sown thinly, as this plant soon spoils if at all crowded, the seedlings drawing up weak and spindly. Successful results depend largely on keeping the plants strong and sturdy at all stages of their growth. Thus the seedlings should, as soon as possible, be pricked off singly into small pots, putting them in right up to the seed leaves, as they send out roots freely from any part of the stem. They should be potted on as they require it, until they are in 6in pots, in which they will flower. Use a rich potting compost and make it moderately firm. These plants enjoy liberal feeding when in full growth, and after the seedling stage should be grown in an ordinary greenhouse temperature, and during the summer months in cold frames. Poor examples of this plant that one usually sees are generally due to their being grown in too high a temperature.

Impatiens Sultani, I. Holstii and their varieties are very useful for the greenhouse, and distinct varieties are usually propagated by means of cuttings, which root readily at any time in a warm propagating case. As they are quick-growing they soon make useful plants for decorative work. Stock is also easily raised from seed sown at this time; and in the case of I. Holstii a wide range of colour varieties can be obtained. They are best grown in an intermediate temperature until they approach the flowering stage, when they should be removed to a cool greenhouse.

Impatiens Oliveri.—This beautiful species from Uganda is very useful for furnishing large conservatories, either planted out or grown as large specimens in tubs. Such plants flower more or less all the year round. This plant is easily increased by means of cuttings, which root readily at any time in a close case. If grown on into 6in. pots, they make useful plants for the stages, potting on plants for specimens into large pots or tubs.

Celosia cristata.—This plant is by no means so popular as it used to be, although some still value it for its bright colours and extraordinary shape. C. cristata pyramidalis, with its plume-like growths, is excellent for decorative work. If several sowings are made from now onwards, these plants may be had in flower until early winter A pinch of seed according to requirements should be sown in a warm house, and in their younger stages the resultant plants are best grown in a temperature of about 55° Fahr., gradually inuring them to cooler conditions as they approach the flowering stage. Good useful plants can be grown in 48-sized pots, while the taller-growing strains may be grown on into 8in. pots, in which they make fine specimens some 3ft. in height. These plants are somewhat subject to attacks by thrips and red spider. The former can be prevented by frequent light fumigations, and the latter by the use of the syringe. They are also very subject to attacks by begonia mite, but this pest is easily prevented by the occasional use of the sulphur vaporiser.

Amaranthus tricolor splendens with its brilliant coloured foliage, succeeds under the same treatment as that indicated for celosias.

FOGWILLS Guide to Garden Success and Large

— Illustrated —

Catalogue of "BEST-RESULT"

SEEDS

SPECIALITIES:

TOMATO. Fogwills' Red King. Beautiful smooth glossy fruit of a rich deep scarlet, medium size, solid and of fine table quality. Immense cropper. 1/- and 2/6 per packet.

FOGWILLS' "GAY GARDEN" Collection of Choice Flower Seeds. 10 varieties, packed separately, 2/3 post free

DIGITALIS. (Foxglove). "The Shirley." A magnificent strain raised by the late Rev. Wilks, growing 5 to 7 feet high, with enormous flowers, ranging from white to deepest rose and wonderfully blotched and spotted dark maroon, crimson and chocolate. Award of Merit R.H.S. 1/- per packet.

AQUILEGIA (Columbine). Fogwills' Superb Strain of Long-spurred Hybrids. One of the finest strains in commerce, with extra large blooms in exquisite shades of lavender, blue, pink, orange, mauve, salmon, yellow and white. 6d. and 1/- per packet.

LILIUM HENRYI. The Orange-Yellow Speciosum. One of the most beautiful of Lilies, each plant bearing about 20 large flowers of a rich deep orange-yellow with dark green foliage. For pots or garden. Extra large, 10 to 12 inch bulbs. 1/9 each. 20/- per dozen.

GAILLARDIA. Fogwills' "Gold Medal" Strain. Enormous flowers and very stout habit. A grand new improved strain. Entirely distinct from the old kind. 6d. and 1/- per packet.

ANTIRRHINUMS. Fogwills' Guildford Mixture; lovely colours, including bright scarlet, raspberry red, dark crimson, old gold, orange and flame colour, coral pink, canary yellow and pure white. 6d. and 1/- per packet.

All orders carefully packed and carriage paid for cash with order. Everything guaranteed to give satisfaction.

Abol Specialities

Never-failing reliability distinguishes all Abol Garden Specialities, and they are *safe*. Ask your Nurseryman or Seedsman for interesting descriptive folders. In the event of any difficulty, please write to the makers.

Abol Insecticide

Non-poisonous. A sure kill for Insects and Mildew on Roses, etc. Invigorates the plant and refreshes the foliage. Used in the Royal Gardens.

½ pt., 1/4; pt., 2/2; qt., 3/4; ½ gall., 5/3; gall., 9/6.

Abol Patent Syringes

Specially recommended by the National Rose Society. Give a perfect spray, which may be varied from fine to medium or coarse. Last a lifetime.

No. 4 (1 × 14), 16/4; No. 5 (1 × 20), 21/-; No. 6 (1½ × 20), 26/-. Bend, for directing spray to undersides of leaves, extra, 1/6.

Abol Fertilizer

An all-round horticultural plant food. Highly concentrated. Efficacious and economical. Easily applied. Wholesome to handle.

Pkgs., 10d., 1/3 and 2/-; 7lb., 3/-; 14lb., 5/-; 28lb., 8/-; 56lb., 14/-; 1cwt., 25/-.

Abol Lawn Sand

Renovates patchy and impoverished lawns. Kills weeds and daisies and improves the turf. Once tried always used.

Pkgs., 10d., 1/3 and 2/3; 7lb., 3/-; 14lb., 5/-; 28lb., 8/-; 56lb., 14/-; 1cwt., 25/-.

Abol Soil-Pest Destroyer

A quick, sure and economical remedy for wire-worms and all soil insects.

Pkgs., 1/- and 1/9; 7lb., 2/10; 14lb., 4/6; 28lb., 6/6; 56lb., 11/-; 1cwt., 17/6.

Abol Weed Killer

Poison. Clear paths and walks of weeds.

Liquid: ½ gall. tin, 4/-; 1 gall., 7/6; 2 gall., 14/6. Powder: Tin to make 12 galls., 2/-; 25 galls., 3/6; 50 galls., 6/-.

Abol Shading

For glass of greenhouses and conservatories. Easily mixed and applied. In White, Light Green or Dark Green.

No. 1 (200 sq. ft.), 1/8; No. 2 (400 sq. ft.), 3/-; No. 3 (800 sq. ft.), 6/-; No. 4, 11/-; No. 5, 20/-.

Also Worm Killer, Pneumatic Sprayers, Hose Terminals and Garden Hose, Magnifying Glasses, White Fly Compound.

EUROPEAN ORCHIDS ON SAND

AFTER the chalk district of Kent probably other limestone areas in England are the richest in orchids,as indeed is the case with most flowering plants in countries where limestone is prevalent, but not a few orchids thrive well on maritime and other sands.

In the interesting article by Mr. Hadden on "Some French Orchids" (page 46), he not only remarked that he did not see any bee orchids in France except in one wood where Cephalanthera rubra grew, but that this typically limestone plant (Ophrys apifera) does occasionally turn up in a district where there is very little limestone, and it is usually an exceptionally well developed and richly coloured specimen. I can substantiate this peculiarity by saying that the finest and most abundant bee orchis I ever saw in France was in April, 1913, growing on the sandy Isthmus de Gieus, connecting the mainland south of Hyères with the rocky and picturesque Presqu'île de Giens, surrounded by the blue Mediterranean. Here they were on pure sea sand among low grasses and other somewhat dwarf plants. I took several photographs of this colony.

On a corresponding strip of more bushy, but still sandy land on the other or east side of the extensive Salt Pans, the tall, robust and broad-leaved Orchis (Barlia) longibracteata, with its handsome but sickly scented flower spikes is conspicuous from January until the end of March. It is the earliest European orchid, and, often, its fleshy spikes can be seen at Christmas after pushing through the humus of decaying needles of umbrella pines. So abundant are these orchids in confined areas near Hyères that sometimes a sort of emulsion is made from the mucilage of their stems.

In Britain, though the bee orchis is so frequent on certain downs and poor pasture, chiefly on carboniferous limestone, chalk, lias and oolite, some of the finest and most brilliantly coloured specimens were growing last June amid marram grass on pure sea sand on the dunes north of Burnham, Somerset, and this plant was recorded as abundant from those sandhills in Watson's "New Botanist's Guide" (Suppl.), as long ago as 1837. Among the Bee orchids on June 7th I noticed a single plant of the pyramidal orchis, which in Somerset is most frequent on lias soil. The beautiful Epipactis palustris still grows on the damp sand bordering what once was a considerable pool amid the Burnham sand dunes, but which the exigency of golf has caused to be partly drained.

In the extreme South of France several species of Ophrys and most of the Serapias genus grow on rough ground overlying sand—both sea sand and sand of old geological formations. On the latter soil they are frequently amid pine trees or certain species of cistus. Probably on some sandy coasts, *e.g.*, between Burnham-on-Sea and Weston-super-Mare, the sand contains a fair percentage of lime in the form of cretaceous matter from the innumerable shells on the beach below high-water mark. The salt on such dunes is more easily washed out by rain than in certain other places.

In regard to the cultivation of terrestrial orchids, doubtless the recent remarks in these columns about the Snakes-head thriving best with the help and support of grasses and other suitable plants would apply to most of the orchids. In the same way nearly all the smaller gentians grow better in turf than on the gravel of moraines. Actually, in nature, it would appear that there is a reciprocity of accommodation among many of the phanerogams which is almost akin to that of some of the cryptogams And the increasing number of plants, especially among scrophulariaceæ, which have been found to be semi-parasitic, together with the study of saprophytes and the large number of epiphytes is an aspect of the subject not to be overlooked in modern gardening. The strange looking limodorum, mentioned on page 46, with its livid violet stem, bright violet and white flowers soon fading and turning yellow, is itself parasitic on various plants, especially the roots of pines. This orchid is beautifully coloured in Bicknell's "Flowering Plants and Ferns of the Riviera," where also Plate 57 well shows the distinction between the three European (and British) cephalantheræ. But there is a better plate of the great Orchis longibracteata in Moggridge's scarce and expensive "Flora of Mentone." It is not surprising that Mr. Hadden has never seen any illustration which did justice to the wonderful rosy blooms of Cephalanthera rubra, when we turn, *e.g.* to the miserable dull purple colour of the plate in "Sowerby," Ed. III. In the second and first editions of that work the colouring of this and nearly all the plates is far better, though some of the earliest colouring of the third edition is just tolerable. In France this was the orchid whose beauty appealed most to your correspondent, particularly when growing "beneath the noble plumes of Spiræa Aruncus." In such surroundings or when intermixed with the pure white blossoms of C. ensifolia, it is indeed a joy for ever. H. STUART THOMPSON.

BOOK REVIEWS

DISEASES OF CROP PLANTS IN THE LESSER ANTILLES.

THE treatment of the subject in this work* may be compared with that of Dr. Bewley's recently published "Diseases of Glasshouse Plants." In both cases the authors are convinced of the intimate correlation between the incidence of disease and agricultural or horticultural practice, and have used this fundamental theory as a basis for the connected presentation of the various diseases dealt with. Throughout the book one is conscious of Mr. Nowell's first hand practical knowledge of agricultural conditions in the West Indies, and their influence on the prevalence of certain diseases of crops grown there. For this reason the book will be invaluable to planters and plant pathologists, not only in the West Indies, but elsewhere as an up-to-date treatise on the principles of plant pathology.

The book is divided into two parts. In Part I the first section deals with the causation of disease by fungi, bacteria, infective viruses, phanerogamic parasites, eelworms and non-parasitic agencies, and includes a discussion of the relation between insects and plant diseases. The second section treats of methods of prevention and control. The various well known fungicides and their application are dealt with in detail, and chapters are given on certain special classes of disease such as wood-rot, "damping-off," and fruit rots. Plant disease legislation is also briefly discussed.

The second or special part of the book is prefaced by a general account of agricultural conditions in the Lesser Antilles. Then follow chapters on diseases of West Indian crops, classified as general diseases (not confined to one crop only), and those of permanent crops (such as cocoa and cistus), and arable crops (banana, sugar-cane, cotton, etc.).

The book is clearly printed and copiously illustrated by line drawings and photographs. —E. M. W.

* DISEASES OF CROP PLANTS IN THE LESSER ANTILLES, by William Nowell, D.I.C. Pages xix and 383, 150 Figs. Published on behalf of the Imperial Department of Agriculture by the West India Committee, 14, Trinity Square, London. Price 12s. 6d.

A MANUAL OF SPRAYING

MANY books have been published on this subject, but as our knowledge of pests increases, so also must the methods of control be altered and more advanced and scientific treatment be employed. This little book* fulfils many requirements in that respect and contains much that is useful. The tables at the end of the book are, indeed, of extreme service, permitting of a rapid way of determining the spray to be used. The book will appeal to the more scientific grower. It is rather expensive for its size, but merits a trial by anyone who wishes to have a handy and instructive manual on the subject.

THE CULTIVATED EVERGREENS.

A LONG-FELT want has now been filled in the horticultural and arboricultural world by the publication of this volume† by Messrs. Macmillan and Co. It is edited by L. H. Bailey, which is a hall-mark to its value. The book is more a compilation of a series of articles, each contribution having been written by an acknowledged authority on that particular subject. The volume, however, loses none of its excellence in having been so treated, as each chapter follows on readily to the previous one, giving a good connected account of the treatment and cultivation of evergreens.

The first four chapters deal with the attractiveness and richness which the conifers lend to the landscape, their cultivation propagation and adaptation,and last, but by no means least, the diseases, both insect and fungoid, which continue to attack these ornamental conifers. The chapter on the cultivation and propagation is somewhat brief, but deals with the subject in a clear and concise manner. The soils to be used, the transplanting and treatment of conifers, propagation by seeds, cuttings and graftings all being given a few words in turn. A most useful chapter to those intending to plant, is that on adaptation. The information has been collected from a wide knowledge and experience of different climates, topographical and soil conditions all over the States and their effects on the various species of evergreens. To each species is devoted a few lines, giving the important cultural points. More stress might have been laid on the chapter devoted to entomology and mycology, but, of course, American conditions differ from those found on this side, as indigenous trees are more fitted to withstand the attack of injurious pests and diseases. A most interesting and helpful systematic classification of these conifers, cultivated in North America, is to be found in Part II. The nomenclature is strict and an important point to the horticulturist is that all sub-divisions of a species have been treated as varieties. There is a key to each of the genera, with, in addition, a specific key.

A most useful chapter touching on broad-leaved evergreens brings one to the end of an interesting trip through the evergreens of North America. The genus rhododendron might have been dealt with more fully, since recent discoveries in China warrant its more intensive cultivation. The typography is good and the book is copiously illustrated. The half-tone plates are worthy of notice, while the illustrations in tint bring out the various points and detail with exceptional clarity, meanwhile maintaining a natural appearance. It is a book which one who is interested in horticulture and arboriculture would find of extreme value and service to have on his library shelf.—G. C. T.

EXPERIMENTAL GARDENING

IN the last issue of THE GARDEN I said something about the fact that half the fun in gardening is in finding out the requirements of plants. This may require some explanation, and may, indeed, offend the susceptibilities of some gardeners.

Gardeners may, perhaps, be divided into two classes: those who are satisfied with plants as they find them, and those who are always anxious to investigate new plants. The former love beautiful surroundings to their houses, and once they are obtained their interest in their garden is over for the season. They are worthy of all praise, for they consist of that solid class who have made our gardens famous throughout the world for an innate sense of beauty and a feeling of repose. The other class consists of those restless spirits who have at the bottom of their hearts an intense desire for discovery, that desire which makes us the greatest exploring and colonising nation. Many people consider this trait hardly respectable, but there it is; it is born in many of us. It makes no difference whether we crave for the discovery of new plants in the wild, or the trial of new and rare plants at home, or the formation of new varieties and hybrids: that feeling is there and it is impossible to smother it.

Sometimes the first class is inclined to become impatient with those who are keen experimenters. They say, or more politely think, that there are so many fine plants in the garden that it is needless to find or manufacture more. But, ultimately, even they have to fall into line, for new plants, whether species or hybrids, gradually percolate into general cultivation and they are forced by the constant repetition of the value of a plant to include it in their garden.

It is amazing how easily a plant gains popularity. The case of Lonicera nitida is typical. It was introduced by Mr. E. H. Wilson from Szechuan in China in 1908 and although eminently satisfactory as a hedge plant and easy to propagate, yet it languished in involuntary retirement until the last six months. The first seed of popularity was sown by Mr. Eley in his "Gardening for the Twentieth Century," when he says that it "stands out as one of the best for an evergreen hedge of 3-5 feet within the garden." The next jolt was given by Mr. Avray Tipping in the columns of this paper, where it was thought worthy of an entire article to itself as a shrub of quality for an evergreen hedge. Since then it has never looked back, and never will, unless something better comes along.

We have had letters galore about it, asking where it can be obtained, and for how much, asking if it is absolutely hardy, asking if it is wholesome to cows and poultry. And yet, if it had not been gently kicked into action, it would have remained in a staid and stately oblivion. It might have been shown as a rare Chinese shrub, only to be obtained from a few nurserymen at a cost prohibitive to mass planting as a hedge. Now the stock is being rapidly increased and the cost lowered. This would have been impossible but for the experimenter class.

On the other hand, there is the experimenter who overworks his subject: who is so obsessed with the value of some family that he turns into a collector pure and simple, a collector who might just as well be cornering stamps or silver spoons. Everything is meat for his appetite, and the good and the bad are as keenly sought after. But even he has his uses, for sooner or later he will come across some plant which will have a universal appeal, and, after he has titillated his fancy sufficiently, his innate sense of the fitness of things will conquer and he will throw open his find to the gardening public, who will benefit by it.

It is amazing how much still remains to be done in finding out when and under what conditions many plants will flourish to best advantage. Really very little is known about the plant world, and anybody with a garden, however small, can help to increase our plant lore by constantly keeping his eyes open.

As I have pointed out before, the gardening public is not a close corporation, and to keep up our undoubted superiority in this, the finest of all occupations, it is necessary that everyone should lend a hand as a member of the experimental class. Everything helps in horticulture and horticulture never sits still.

AMONG OTHER ARTICLES IN OUR NEXT ISSUE WILL BE:

BORDER CARNATIONS, by J. Coutts.

VIOLAS AND PANSIES

BY HOWARD H. CRANE.

ALTHOUGH FLOWERS OF LONG STANDING IN GARDENS, MUCH HAS BEEN ACCOMPLISHED WITHIN THE LAST FEW YEARS IN IMPROVING THE VARIOUS STRAINS.

THE milder influence of spring should now be infusing fresh life into plants of violas and pansies. New growth will become apparent, both in the clumps of old-established plants that flowered last year, and also in the young plants which are the result of cuttings inserted in the frames last autumn.

Now is the time to get the ground allocated to these new plants finally prepared and made ready for their reception. No matter whether the violas or pansies are to be planted in masses in beds by themselves, or whether they are to be introduced in the foreground of a hardy flower border, the grower will be well repaid by giving particular attention to the soil on the lines to be indicated.

It is presumed that the ground has already be turned over and, where possible, trenched ; if not, it should be dug without delay, incorporating at the same time some well rotted manure, either vegetable or animal. If the soil is of a heavy character, road sweepings or other material of a sharp, gritty nature should be dug in as well. Light soils can be considerably improved by the addition of cow manure—and, indeed, to succeed in growing these plants at all well on land that is naturally light or sandy, it is essential that manure of a retentive nature be added. In any reasonably good garden soil they will do quite well.

Violas and pansies do best in a sunny situation ; a position where they are sheltered from the sun during the hottest hours of the day suits them particularly well. They will grow in a semi-shady place, but will not do so well as if planted where they get a fair amount of sun.

Planting should be taken in hand during the next week or so, unless there are indications that weather conditions are likely to be and to continue severe, in which case it is better to defer it for a while. Before the time for planting arrives, every effort should be made to get the young plants in the propagating frame or bed in good condition and growth. If the plants are in frames, the lights should be removed at every opportunity in milder weather, replacing them only in the event of severe frost or heavy rain. Except in the case of late-inserted cuttings or backward plants, it should soon be possible to dispense with the frame lights. It is very desirable for the young plants to be hardened off before being shifted. They will pick up and become established far more quickly than otherwise would be the case. Water should be given as occasion requires.

In the case of small or backward plants it is well to sprinkle a handful or so of sand or grit among them, and press the soil between the rows well down in the event of disturbance by worm-casts, etc. The thin edge of a board answers the purpose excellently. Where plants have not been propagated from the grower's own stock but are being obtained from the nurseryman, it is highly desirable that they should be put in as soon as possible after delivery. If it is not possible to get them in without delay, they should be unpacked and " heeled in " in a sheltered spot in the garden.

Ground already dealt with that has weathered the past winter should, with the approach of drier conditions, be in an ideal state for planting purposes. It should now be well

THE WELL KNOWN VIOLA MAGGIE MOTT.

THE RICH YELLOW BLOOMS OF SIR R. BADEN-POWELL.

Digitized by Google

broken up and the surface soil well raked over until a fine tilth is obtained. If, at the time of planting, a handful of a special compost is placed around the roots of the young plants they are the more likely to become quickly established and go ahead at once. A suitable compost is one made up of equal parts of good loam and leaf-soil or well rotted manure and a quantity of sand or road grit sufficient to make the compost porous. The ingredients should be passed through a coarse sieve. Personally, I always have a compost of this nature at hand when planting violas and pansies. Plant firmly. Should the soil be in a dry condition, give water as soon as planted, except in the case of plants put in late in the day or when there is a likelihood of frost.

To reduce the risk of loss in the case of special or valuable varieties, it is decidedly worth while, in the event of severe

SHADES OF MAHOGANY AND BRONZE. VIOLA MRS. MARRISON.

weather, to afford them the shelter of boards or pots until established. Some varieties of pansies, especially, need attention in this direction.

Established plants of violas of last year's growth are, in the case of tufted varieties, now good sized clumps and will soon be ready to put forth a profusion of flowers. Fine early effects can be obtained by leaving these old plants in the border undisturbed for a couple of seasons. I always rely on obtaining a good display early in the year by adopting this course. The soil round each plant should be lightly forked over and, if possible, some old manure worked in. The response to such treatment will be apparent in due course and is well worth while. Any straggling growths should be removed. After the plants have made a display, they may either be cut back or moved to the reserve garden—to make room for other plants less hardy—and used for propagating purposes.

Stock may be increased at the present time by breaking up or dividing any old plants that have served their purpose last season. Varieties of compact habit and fibrous root growth are obviously the most suitable for use in this way. Such plants can be roughly divided either into fairly large pieces or into smaller pieces of single stems each with a root. In the former case such divided pieces may be planted straight away into fresh flowering quarters, but the smaller pieces will be better plants in a specially prepared bed, or, better still, inserted in a propagating frame. If the latter plants are given the protection of a frame-light for a week or so, they will grow rapidly and make good specimens for planting out later in the season—during May. Plenty of ventilation should be given in the frame.

Few plants in the garden give such a continued brilliant display over so long a period as do violas and pansies, particularly the former. Comparatively little cultural trouble is involved to obtain excellent results, and stock is maintained at a minimum of labour and expense. As is the case with most other flowers, the plants should be grown in masses to obtain the best effects. A dozen plants put in some 6ins. apart will, in the course of a season, develop into a mass some 3ft. across. To those who have not grown violas as a groundwork for other taller-growing plants I would recommend the trying of such an experiment. In many gardens one now sees violas used in this way in conjunction with roses and carnations, and there is no reason why their usefulness should not be extended. Beds that are otherwise uninteresting during the major portion of the summer or autumn can be made effective for a very much longer period by interplanting with violas and pansies of selected varieties.

Planting may safely be effected at any time now up to the middle of May and even later, but it is expedient to plant in good time so that the plants may become well established before the hot weather arrives.

Care should be taken to acquire and grow only such varieties as are of robust constitution and of as compact a growth as possible. Varieties of a straggling habit should be avoided. They lack the fibrous root growth that is so essential to the plant in hot and dry weather.

A note is appended of a few of the best violas now in commerce, all of which can be depended upon to do well and to serve a useful purpose in the garden.

One of the most popular white violas is Swan, a variety now largely grown by market gardeners and sometimes listed as " White Swan." The flower is quite rayless and the blossoms are borne well above the plant. It grows vigorously, but is at the same time fairly compact in growth. Snowflake is another useful rayless white variety, not quite so bright as the foregoing, but very free-flowering. A particularly charming flower is Peace. The colour is creamy white, delicately tinted blush towards the outer part of the upper petals. The rayless blossoms are large and circular, and the growth is very compact.

Mauve Queen is a robust variety of good habit, bearing flowers of a bluish mauve hue; a very useful sort. John Quanton is a light mauve flower and is a very free-flowering variety. It is a robust sort and of distinct value in large masses. Maggie Mott is a particularly well known variety of a lavender mauve tint. The constitution of this viola is very strong and the growth is peculiarly tufted. The flowers are, however, a trifle lacking in substance, and they wilt rather soon in hot weather.

The striking colour of W. H. Woodgate—a bright lavender blue—makes this variety greatly to be desired in most gardens. It approaches a pale blue more nearly than any other viola I have either grown or seen. The habit is good. Newton Mauve is a very useful sort with medium-sized flowers of lavender violet; a variety well worth growing for its colour, combined with a compact habit of growth. A distinct flower is Dunbryan. It has a tufted habit of growth, bearing, freely, flowers of a pale lavender colour.

Of cream and yellow sorts there are many good varieties from which to choose. Lady Knox is a refined flower of pale primrose, and Primrose Dame is a flower of somewhat deeper colour. Both are free flowering and good kinds for garden decoration. The flowers of Margaret Wood are lemon yellow and rayless. This variety is a good bedder. Luiggi is a robust-growing pale yellow sort and possesses a good habit. One of the most popular yellows is Moseley Perfection, a variety grown a great deal by market gardeners. The flowers are golden yellow, large and rayless. It grows strongly and the habit is fairly good. Baden-Powell is another very rich yellow sort of moderately good habit.

A very old, but nevertheless extremely useful, sort is J. B. Riding. This is crimson mauve in colour and of singular usefulness in the garden for massing. It is very compact in growth. William Daniels is a very fine variety of purple

Digitized by Google

violet colour. The flowers are large and the growth compact. John Forbes is another variety of similar type to the before-mentioned, in colour a deep rosy violet, and of velvety substance.

Mrs. Chichester is a popular variety that always does well. Strong-growing but tufted in character, the large flowers of white ground edged or suffused purplish mauve are always much admired. Dr. McFarlane is a viola raised many years ago, but still one of the best of its class for good habit and free-flowering characteristics. A flower of velvety substance, upper petals mauve, lower petals dark bluish purple. An excellent sort is Mrs. Marrison in shades of mahogany and bronze.

With regard to pansies, any of the following standard varieties will be found exceedingly fine in respect of their individual flowers; they are also quite good for bedding purposes, but it must be remembered that the growth of fancy pansies is never so compact and tufted as that of violas: John Douglas, John Lister, John Mackinnon, Mrs. A. H. Lister, Sir John French, Sir Douglas Haig, Mrs. J. Johnston, William Gray and William Spalding.

Most of the leading seedsmen grow their own selected strains of fancy pansies in distinct sorts, which are of a very wide range of colour. I would recommend the gardener who desires certain colour effects in the garden rather than individual flowers conforming rigidly to certain set standards, to grow some of these special strains. The flowers are invariably large and handsome.

A SELECTION OF SHRUBS for the ROCK GARDEN

BY W. IRVING.

(*Continued from page* 183.)

THE genus Gaultheria is a large one, consisting of some ninety species of very ornamental, hardy or greenhouse shrubs, many of which have their home on the American continent. Others are found in the Himalayas, China and New Zealand, among other places. Some of the smaller-growing kinds are excellent plants for the rock garden, thriving well in a peaty soil, and easily increased by division or by layers. G. nummularioides is an ornamental, hardy evergreen from the Himalaya, suitable for clothing a rocky bank or ledge, in a shady position. It has numerous nearly prostrate wiry stems clothed with rounded leaves that have ciliate margins. These are deep green when growing, but change to a dull red in the autumn. The flowers are like those of the lily of the valley, but frequently tinged with pink, and are produced in the summer. These are succeeded in the autumn by very ornamental scarlet fruits. G. procumbens, known as the "Creeping Wintergreen," is valuable for forming a ground carpet beneath taller growing or standard plants that provide a little shade. It only grows about 6ins. high, with branching stems, terminating in tufts of oval green leaves that assume a bronzy tint in autumn. The white flowers are solitary in the axils of the upper leaves and are produced in July, to be succeeded later on by red edible berries. It is a native of North America, and is one of the most easily grown plants, soon making large tufts in suitable situations. On the larger side is G. Shallon, from North-western America and where there is a considerable vacant space this plant will come in very useful. It grows up to 3ft. or more high, the ovate leaves having a toothed margin, while the white pendent flowers are produced in racemes during May. The purple berries of this handsome shrub have a very agreeable flavour and are said to make excellent tarts. One of the smallest kinds is G. trichophylla. It is a charming little bush, only a few inches high, with dark green, shining foliage, the leaves being only half an inch long, with bristly margins. The flowers are pink or white, borne solitary in the axils of the leaves in May. The pretty blue berries are produced very freely, making the plant quite ornamental for a select position. This species is found on the Himalayas, as well as on the Chinese mountain ranges. Other kinds have been introduced into cultivation recently but the above may be considered the pick of the genus.

Another handsome shrub is Genista dalmatica. This Dalmatian broom grows about 9ins. to 1ft. high, with interlacing branches, forming a bushy plant covered with yellow flowers in summer. It is one of the smallest of the family, being practically a miniature of the well known Spanish broom (G. hispanica). It is easy to grow in well drained loamy soil and is best propagated by means of seeds, although it can be struck from cuttings.

A VALUABLE ALPINE BROOM, GENISTA DALMATICA.

Many of the junipers are ornamental evergreen plants, some erect, others of prostrate growth. Juniperus Sabina tamariscifolia belongs to the latter group. It is a low-growing, densely branched and trailing species, with bright green foliage. It is sometimes known as the "carpet juniper" and is an excellent plant for crowning a rocky knoll or bank. Others of this genus suitable for the rock garden are J. fastigiata compressa, a compact little shrub like a column about 1ft. high. It is very slow-growing and looks charming dotted about among other low-growing plants. J. hemisphærica is a curious and interesting little shrub of a dense rounded habit. It only grows a few inches high and is sometimes called the "hedgehog juniper."

Loiseleuria (Azalea) procumbens is one of the most charming of alpine shrubs. This plant only attains a height of a few inches and forms a much branched, tufted mat with small evergreen leaves, bearing pretty flesh or rose-coloured, bell-shaped flowers in early summer. It grows best in gritty, peaty soil, and in a fairly moist position. An inhabitant of the mountains of both Europe and North America, it grows in open, wind-swept positions on rocky ledges and banks, at a fairly high elevation.

Moltkia petræa is a member of the borage family and is closely allied to the lithospermums. Of bushy habit, growing up to 2ft. or more high, it bears a profusion of purplish blue flowers during the summer months. It is a native of Dalmatia, and is easily raised from seed.

A few members of the well known pentstemon family are of shrubby habit and valuable for the purpose in view. Among others is P. heterophyllus, which grows about 1ft. high, with narrow leaves and blue or purplish flowers. It is quite hardy and perennial on a well drained rocky ledge. Another handsome kind is P. isophyllus, from Mexico, which reaches a height of 2ft. or more, with scarlet flowers in long panicles during the late summer. P. Menziesii is a dwarfer plant with small leaves and rosy red flowers. This plant is being sent out now under the name of P. cristatus, but the latter is really a coarse-growing, erect species. P. Scouleri is a very handsome shrub, about 1ft. high, freely branching and evergreen. The large pale purple flowers are produced in great profusion during May. Like P. Menziesii, of which it is considered a variety by some authorities, it is a native of North-western America. Others might be enumerated, but the above comprise the best selection for general purposes.

The milkwort family (Polygala) contains two or three pretty evergreen, shrubby species that are hardy in the rock garden. P. Chamæbuxus is a plant of the mountain woods and is found in many parts of Europe. It grows about 6ins. high and bears, in early summer, cream coloured or yellow flowers tipped with purple. There is also a purple-coloured form. Both are easily grown in a peaty soil in shady positions. P. Vayredæ is a narrow-leaved form from the Pyrenees.

Rhododendrons are represented in the Alps of Europe by two distinct species, namely R. hirsutum and R. ferrugineum, both of which are common in Switzerland. The former species is always found on granitic soil, while the other belongs to the calcareous zone. They are similar in habit, growing about 1ft. to 2ft. high, of freely branching, bushy growth and both are commonly known as "Alpine Rose." R. hirsutum has green leaves that are hairy on the margins, while the leaves of R. ferrugineum are covered with rusty coloured dots beneath, and are quite glabrous. Both have flowers of a rosy scarlet colour, produced freely from May to July. There are also white-flowered forms of both species occasionally found in the Alps, but they are not common. These plants are easy to grow when planted in the soil suited to their requirements, either in full sun or partial shade. They are ideal plants for the rock garden. In addition to the above we have the choice of a large number of low-growing rhododendrons which have recently been introduced into this country from the mountains of western China. Several of these are now in cultivation and have proved of great value for furnishing rocky slopes or ledges. One of the earliest to be introduced was R. intricatum. This was sent home by Mr. Wilson when collecting for Messrs. Veitch and Sons, who flowered it in March, 1907. It is a densely branched shrub, which in its native habitat grows from 1ft. to 2ft. high, densely crowded with small leaves. Terminating the branches are lilac coloured flowers, mostly in clusters of five, very freely produced in the early spring. This species has proved to be free growing, easily propagated by cuttings and seeds. Closely allied is R. impeditum, also known as R. fastigiatum. This is one of Mr. Forrest's collecting, and is dwarfer and more spreading in habit, with smaller leaves and deep lilac-coloured flowers in which the stamens much exceed the corolla. R. calostrotum is a low-growing bushy species with large rose-coloured flowers and a still dwarfer species is R. prostratum, which Mr. Forrest found up to a height of 16,000ft. on the Lichiang range of mountains in Yunnan. Here it only grew a few inches high, trailing over rocks at the extreme limit of vegetation. It has hairy leaves and large, wide open, rosy purple flowers. These are only a few selections from this extensive genus and many others might be adapted for growing in the rock garden.

Rhodothamnus Chamæcistus is a handsome plant, closely allied to the above genus and often included in it. On the Alps of the Tyrol it is invariably found at altitudes of a few thousand feet on moraines with a little humus. It forms neat, compact and bushy tufts about 6ins. high and has evergreen, light coloured, rather small leaves covered with hairs. The flowers are saucer-shaped, large and vary in colour from deep purple to rose colour or white. It is a lime-loving plant and should be

THE DWARF PENTSTEMON MENZIESII.

CONIFERS, HEATHS AND OTHER DWARF SHRUBS IN THE ROCK GARDEN.

Digitized by Google

planted in a sunny position in a crevice or small pocket between stones, which keep the roots moist and cool. It is not often seen in good condition as it is somewhat difficult to establish. A loamy soil suits it best, but perfect drainage is essential.

The bilberry or whortleberry family, Vaccinium, is a large one, and consists mostly of shrubby plants that are too tall for the average rock garden. Two or three species, however, are very useful for ground work in the shady parts, planted in peaty soil. The common whortleberry (V. Myrsinites), is a native of this country, usually growing in woods, copses, and heaths in hilly districts, flowering from April to June. It is a deciduous plant with rigid stems about 1ft. high clothed with ovate, toothed leaves. The rosy coloured flowers are succeeded by dark blue berries in autumn. V. Vitis-idæa (the cowberry), is an evergreen plant about 1ft. high, with obovate leaves that are dark green above. The pink flowers are borne in short, terminal, drooping racemes, while the round berries are red. It is also a native of this country, chiefly in the mountain districts. Both are easy to grow in soil that contains a proportion of peat, and are readily propagated by division or layers.

TREATMENT OF RHODODENDRON SEEDLINGS

BY L. B. STEWART

SINCE Mr. G. Forrest began his travels in Yunnan the amount of rhododendron seed he has sent home must have been enormous. Edinburgh, in common with many other Botanic Gardens, has benefited greatly through the kindness of Mr. J. C. Williams, who always gave us a liberal portion, thus enabling this garden to become enriched with those beautiful plants. It has been my fortunate position to handle all the seeds sent in since 1919, and as my late chief asked me to take a real live interest in the seed and young plants, I have endeavoured to do so.

My observations are as follows: I find that the seed which has arrived here can be placed roughly into three sections: We have what I call (1) the ordinary brown-coated seed; (2) the clear or greenish clear seed, usually without coat, but when coat is attached it is somewhat transparent; (3) the bridled seed, because it has a band which encloses the seed and finishes off at each end with small twisted tails. This section, however, up to the present, is a very small one.

The sowing is a very particular operation, and much of the success depends upon the amount of trouble that is taken. It is a general practice to fill the pots or pans at the bench, sow in the same place, and then cover without ever removing the pot. This system is always to be condemned, as it leads to a tremendous mixture of seed, and one can sometimes find as many as six or seven kinds growing in one pot. The method which is adopted here at present is to fill the pots at one bin of soil, where the soil is pressed to the required firmness, then the pot is moved along the bench to a clear part where the seed is sown. The pots are then set into a tank or large saucer of water until all the soil becomes thoroughly wet. The water should not be allowed to come beyond the rim of the pot, and should be of about the same temperature as the house in which the seeds are to be germinated. It will be found that after the first two dozen pots have been sown and immersed in the water the water may have fallen to a very much lower temperature, when the addition of a little more hot water will be found necessary. After they are removed from their bath they are placed on a floor and allowed to drain, after which they may be placed on the stage and the seed allowed to germinate. As we never cover our rhododendron seed here with compost, it is found necessary to cover the seed pots with newspapers, thus ensuring a subdued light which tends to hasten germination, and at the same time lessens evaporation. It is found beneficial to keep the seed pots sprayed with a very fine spraying syringe, as this prevents the drying up of the surface of the soil and saves any damping off taking place. As most gardeners know, the cause of damping off is the meeting of the dry and wet areas, therefore by keeping a constant moisture and never allowing the seed pots to get dry this evil is overcome. When the plants have established themselves and are beginning to make roots, they will need a more liberal supply of water to keep them fit. At this time of year, if the seed is fresh, good germination will take place in about twelve to fourteen days, but should the seed be weak it will take longer. It is often found where the seed is weak that it becomes infested with moulds, and it is in cases of this kind that the solution of permanganate should be applied and that at once (see THE GARDEN, February 16th, 1924, page 92).

When the seeds start to germinate it will be found that the ordinary brown-seeded ones have red hypocotyls, and ordinary treatment may be given to them, as they are more or less "good-tempered." They usually like a good quantity of humus in their compost. In the second group we meet with those with the clear hypocotyls. In this group I find they are not fond of humus, and in mixing up the compost only the smallest amount of leaf-soil is used and no peat. The rhododendrons in this group are those Mr. Forrest describes as found growing where peat was used; whenever the young roots touched the particles of peat they either died or were found to be very sick. At that time I made small sowings on pure peat, and none of them ever survived. At the present time I have got a lot of this sort potted in old lime rubble (three-quarters) and pure sand (quarter), and up to the present they are an exceedingly happy family! The third group I would not like to say too much about, as my experience is very limited, but I might venture to say that they look epiphytic and need a lot of air at their roots. The only species I know that is in cultivation is R. sino-vaccinioides.

In mixing up the compost for sowing rhododendrons have plenty of rough sand well intermixed with the soil, and this compost should be put through a quarter-inch sieve. The compost should vary according to the kind of rhododendron being handled—whether they are peat lovers or limestone plants.

After germination, they can be moved to a cooler house and there remain until the time for pricking off. This operation should be done at the earliest possible moment, as the less check the seedlings get the healthier they are at the end of the season. There is no doubt, however, when they are tackled at the very earliest stage a great deal of patience and perseverance has to be exercised, as it becomes a very tedious operation. It is, however, very much more satisfactory to prick off early than to leave the seedlings in pots until they become a fair size before pricking off. As each pan or box is pricked out it should be watered at once through a fine rose and thereafter removed to a frame or house where the lights or the ventilators can be kept closed. Allow the temperature to rise 6° to 7° to give the seedlings an extra good environment to promote root growth. After they have taken hold of the new soil the ventilators or lights may be gradually left a little more open to permit a free circulation of air; but never at any time allow a draught, as there are no outdoor plants which detest draughts more than rhododendrons, especially at this period of their existence.

It will be found by this time that the weather is becoming warmer, and it will be advisable to shade the seedlings which have been pricked off, and this can be successfully done with tiffany. If the house runs east and west, the tiffany should be left hanging down loose in front of the stage. If, however, the house is running north and south, another method will have to be adopted, and that is to tack the tiffany on the outside of the house. The use of the syringe should become "the order of the day" in sunny weather, and should be put away on dull sunless days.

The enemies of the gardener will be found to be very active at this time when much watering and syringing is going on (namely, the liverworts and funarias — the mosses). Hand-picking is about the only way of dealing with these pests when they are living alongside the growing plants. When they appear on the seed pots, however, one or two applications of hot water will kill them.

VIBURNUMS

BY A. OSBORN.

IN common with many other families of hardy shrubs, the viburnums have been considerably augmented by numerous distinct and valuable additions from China. In "Plantæ Wilsonæ" more than thirty species and varieties are recorded. These were collected by Mr. E. H. Wilson during 1907, 1908 and 1910. A number of these had been previously named and described from dried specimens, but we are indebted to Mr. Wilson for the introduction of the majority as living plants in our gardens.

The viburnums are found in three continents—Europe, America and Asia; one species, viz., V. Lantana, extends into North Africa. They include both evergreen and deciduous shrubs, one or two attaining the dimensions of small trees. The smallest we have are V. Opulus nanum, a dwarf, tufted bush about 1ft. high, and V. Davidii, a distinct Chinese species of spreading habit, under 2ft. in height.

The three viburnums most freely planted in our gardens are VV. Tinus, Opulus sterile, and tomentosum plicatum. The last-named comes from Japan, and there are three other Asiatic species being very considerably planted: V. Carlesii, from Korea; V. fragrans, first introduced by the late Mr. W. Purdom, though best known as the viburnum described in such glowing terms by the late Mr. R. Farrer; and V. Henryi, introduced by Mr. Wilson. About eighty species and varieties are in cultivation at Kew, a very interesting and varied family of woody plants, attractive in flower, foliage and fruit.

CULTIVATION.—In good, deeply worked garden soil we generally consider the viburnums to be fairly easy plants to cultivate. There are, however, certain conditions which are desirable if we are to get reasonably good results. In reading of their native habitats we find frequent mention made of woodlands, thickets, forests, borders of swamps or streams and damp hedgerows. Perhaps because we liberally manured the ground and mulched the beds of VV. Opulus sterile and tomentosum plicatum, it was not realised until the dry summer of 1921 that the viburnums were such moisture-loving shrubs. Despite a fair amount of watering, it was a difficult matter to keep some of the plants alive on our dry soil, and a number of the bushes still show the ill effects of the drought coupled with the brilliant sun of that year.

THE GUELDER ROSE, VIBURNUM OPULUS.

THE YELLOW-FRUITED V. OPULUS FRUCTU LUTEO.

We have frequent evidence of the value of deeply cultivated and good holding ground for viburnums in the excellent exhibits of Chinese species seen at the London shows from the Aldenham House gardens.

In addition to the value of a number of viburnums for beds and groups in the pleasure grounds and shrubbery borders, all or nearly all have some distinctive merit in flower, foliage or fruit to add variety and interest wherever planted. By the waterside, in the open or thin woodland and the wild garden, viburnums may worthily find places. V. Tinus, the laurustinus, in gardens of the south and west, is a most valuable evergreen shrub, flowering in mid-winter. For a not too formal and closely clipped hedge the laurustinus is worthy of much more attention from planters.

PROPAGATION.—Seeds and cuttings provide ready and rapid means of increase. The evergreen species, with V. Tinus in particular, root readily in a close propagating frame during July or August; so also does the new V. fragrans from China. Layering provides an easy method of increasing viburnums in the open border. The dainty V. Carlesii can be freely propagated by cuttings, though nurserymen, for quickness, have increased it very largely by grafting, using a common species (V. Lantana for one) as the stock.

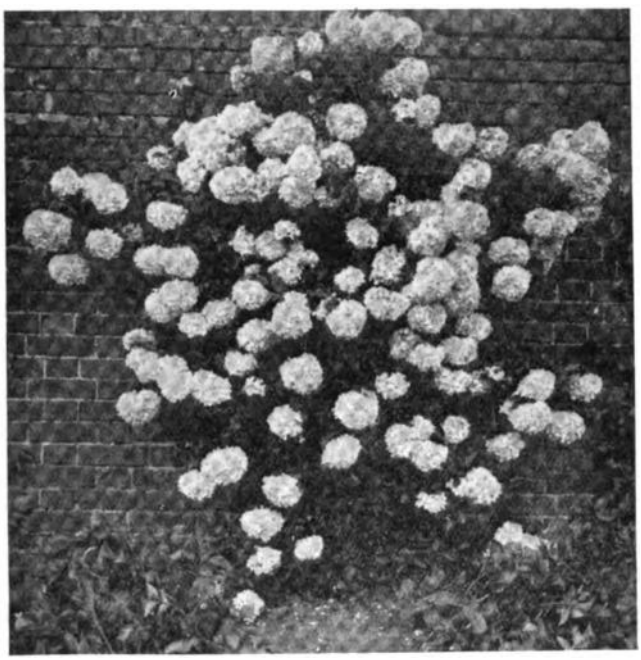
AS WALL PLANTS.—Several viburnums on the borderland of hardiness are deserving of attention as wall shrubs. They may also be cultivated in large pots or tubs, giving them a place on the terrace walks or steps in summer and wintering in an unheated greenhouse. VV. macrocephalum, coriaceum, japonicum and odoratissimum are best with this treatment. In

Digitized by Google

cold northern gardens the laurustinus is treated as a wall shrub, or planted in very sheltered positions.

THE EUROPEAN SPECIES.—Three viburnums are natives of Europe, two deciduous species growing wild in England, the evergreen, V. Tinus, being from the Mediterranean region.

The wayfaring tree, V. Lantana, is a free-growing bush up to 12ft. or more in height. Its value lies in the handsome leaves, which assume rich autumnal tints; large heads of white flowers in May and June; and, at first, red fruits, which ripen a lustrous black. For shrubbery borders, the pleasure grounds and woodland, the wayfaring tree is one of our most valuable native shrubs. V. Opulus, the guelder rose, because of its value for waterside and swamp planting, has been aptly named the water elder. Attractive from early June, when the white flowers are showy, until early winter, when laden with clusters of lustrous red fruits, this plant should be more largely grown. It is not uncommon seen as a large bush or small tree in damp English and Scottish woodland. The glowing red tints of the foliage are very beautiful in the autumn sunlight. As a shrub for the pleasure grounds the snowball tree, var. sterile, is a very valuable tall shrub. The flowers are all sterile, and instead of the flattish cyme they form a roundish head of closely packed blossoms, hence the name "snowball tree." For lawn beds and groups in the shrubbery borders the bushes are very attractive. Bushes of the yellow-fruited variety, fructu-luteo, are a delightful contrast in autumn to the rich red of the type. Sprays shown at one of the fortnightly meetings of the Royal Horticultural Society last autumn indicate how well viburnums thrive in the rich, deeply cultivated soil at Aldenham.



AN IDEAL WALL SHRUB, VIBURNUM MACROCEPHALUM.

The evergreen laurustinus, V. Tinus, a native of the Mediterranean region has been in cultivation in our gardens since about 1596. A free-growing bush of pleasing habit, it grows up to about 10ft. high, or more in the mild climate of the south and west. At Kew the laurustinus is one of the most valuable evergreens and, in addition, flowers most of the winter. Coming from southern Europe, sheltered positions are desirable when planting in our colder northern gardens. The laurustinus thrives in a lighter soil than the deciduous species, growing well in the full sun or partial shade. Its value for hedges has already been mentioned. At first dark or indigo-blue, when the fruits are very showy, they change to black when fully ripe. Several distinct varieties are in cultivation. The variety hirtum (or hirsutum) is conspicuously hairy, and not so hardy as the type; var. lucidum has larger shiny leaves, giving us a distinct and pleasing bush. An erect-growing form is grown in nurseries under the varietal name of var. pyramidale.

DECIDUOUS NORTH AMERICAN SPECIES.—The most convenient method of reviewing the merits and points of interest in their culture will be to take the species in alphabetical order, beginning with V. dentatum. This is a vigorous bush, 10ft. to 12ft. or more in height, with large, coarsely serrate leaves. The small white flowers are borne in flattish cymes 2ins. to 3ins. across, and are followed by blue-black fruits in autumn. This species is a native of eastern North America, where it is known as the "arrow wood," because the Indians used the sucker growths from the base to make arrows. The sheep berry, V. Lentago, is one of the most vigorous members of the genus, attaining sometimes to the dimensions of a small tree if limited to a single stem. The large ovate leaves are finely toothed. The small creamy-white flowers are borne during late May and early June in broad flat cymes 3ins. to 5ins. across. The fruits are blue-black, and in some seasons attract attention in autumn. It is a widely distributed shrub of eastern North America from Hudson Bay to Georgia and Missouri.

V. molle is of robust habit up to 10ft. or 12ft. high, with large, coarsely serrate leaves. The white flowers, borne in flattish cymes 3ins. to 4ins. across, are showy at the end of May or early in June. The small blue fruits are interesting in autumn. V. nudum makes a large bush 8ft. to 10ft. high, with ovate leaves, large clusters of pale yellow flowers and blue-black fruits. The tallest species of the genus with us is V. prunifolium (the black haw), a vigorous bush or small tree up to 25ft. or more in height. In favourable surroundings it is fast-growing, with showy cymes of white flowers in June, these being succeeded by deep blue fruits.

Among the smaller-growing bushes, V. pubescens is worthy of note as it forms a shapely bush 3ft. or 4ft. high, with ovate leaves, flat cymes of white flowers in June and purple-black fruits in autumn. It is found along the borders of woods from western Vermont to Wisconsin, south to New Jersey and Kentucky. In some seasons the dark green leaves change to deep purple in autumn, when they are very striking. V. venosum is a large upstanding deciduous species 9ft. or 10ft. high, with large, coarsely toothed leaves, showy white flowers and blue fruits. (*To be continued.*)

NOTES FROM FLORAIRE

BY HENRY CORREVON.

ROSES.

IN Miss Willmott's book on "The genus Rosa," the first plate has been dedicated to the rare and curious Rosa berberifolia (R. persica), which is the rarest of all those grown in Europe. I first saw it at Ryde in 1885, growing well against a south-facing wall. I brought it home but was unsuccessful with it here at that time. It differs from all the other roses by its simple unifoliate leaf and its abortive stipules. On account of these peculiarities it has been regarded by Lindley and Dumortier as belonging to another genus. It is a small scrambling shrub, 2ft. to 3ft. high, covering over the ground, and bearing, in June, numerous small yellow flowers, with brown red spots at the base of the petals. In distribution, it ranges from Persia and Turkestan eastwards to the Atlas mountains and the desert of Dzungaria, growing there as a pest between the stones and considered as dangerous to sheep owing to its possession of very acute thorns.

In some places R. berberifolia is a weed, while in others it is extremely difficult to grow. I was unsuccessful to begin with, both in my attempts to graft it on R. spinosissima and also in making cuttings.

From 1890 to 1893 I obtained several well rooted plants from Damman at Napoli, where the shrub was somewhat troublesome. It flowered all right in 1902, but died a few years later. At that time, it may be mentioned, the plant was out of cultivation in England and also in Napoli, and hence I was unable to obtain a further supply.

In February, 1906, however, I obtained seeds of it, and since that date the plant has become quite acclimatised here, flowers well, but never seeds. In one bad part of the garden

Digitized by Google

is as troublesome a weed, as it was at Napoli in 1890. It runs everywhere and propagates easily by runners. I have distributed several plants since that time and I understand that it succeeds in many gardens. One of the first points to consider in its propagation is, that it requires a very dry place and a light soil, exposed to the sun. It may be remarked that here it is found running under a path composed of stones.

We also grew here a small rose which is the most minute of all those in the genus. I believe it is unknown in England, where I have seen some small R. Lawrenceana, but never such a dwarf as R. Rouletti. This is a tiny, bushy shrub, about two inches in height, covered with small carmine-pink sweet-scented flowers, not exceeding half an inch in breadth. It flowers continuously from May till December. It was grown for many years in a mountain village, Mauborget above Grandson (Jura), 3,000ft. altitude, but ultimately disappeared from there when the village was burned. It turned up, however, in another village near the Lake of Neuchatel, where I found it some years ago, thanks to the help of my friend, Dr. Roulet, to whom I dedicated this rose. The origin of this Liliputian plant (the smallest of all the roses), is unknown. The peasants at Mauborget say that it has been grown in pots on the windows for centuries, but never out in gardens. On looking over rose literature I found, in de Candolle's "Prodromus" (Vol. 2, page 600), a reference to a form of R. indica—called humilis (Seringe) and pumila (Redouté), which is said to be "minutis" and occurred at the beginning of the nineteenth century. This species which I have found and described above is still smaller than this.

It is planted out on ground well exposed to the sun, and it does fairly well there, although it does not flower so profusely as when it is in small pots. It seldom grows higher than four inches and the flowers as well as the leaves are never larger than those grown in pots and it thus remains the real dwarf of all the roses.

EDRAIANTHUS PUMILIO, A DWARF AND DENSE TUFT OF SILVERY LEAVES, WHICH IS COVERED IN MAY AND JUNE WITH HAIRY LILAC LAVENDER CUPS.

EDRAIANTHUS.

Difficulties in plant nomenclature are continually cropping up, and the case of Edraianthus is one in particular. Edraianthus has many synonyms—Hedranthus=Wahlenbergia =Campanopsis=Campanula of certain authors. The correct name is probably that of Hedræanthus. We have grown them for two years in our alpine garden on the Jura, where the calcareous soil and the dry situation appear to be very suitable for them. So we are now able to make a study of them and settle this vexed question.

From a gardening point of view, we can separate the Edraianthus series into two groups: (1) E. Pumilio, with one flower on each stem, the flowers being sessile and surrounded with more or less long bracts; (2) flowers in heads (capitula), after the type of E. dalmaticus.

The plants in the first group are some of the alpine cushion type, with masses of flowers, shortly stemmed, covering in the main the mass of leaves. E. Pumilio takes the form of a dwarf and dense tuft of glaucous silvery leaves, very short and acute, entirely covered in May and June by the slightly hairy lilac lavender cups. There is frequently no stem, but if present it is a very short one. It grows in the Biokovo Mountains of Dalmatia, where it was discovered in 1818 by Portenschlag in limestone arid rocks in the highest regions. Its cousin, E. pumiliorum (E. dinaricus), has longer leaves, grows in looser cushions, less silvery and almost always bristly with hairs. The purple flowers stand up from the main mass on slender and weakly stems. Professor Beck remarks that it might be a shade form of Pumilio. It was discovered on Monte Javor in 1832.

Another near relative is E. Wettsteinii, found on the Rumia summit in Montenegro in 1891. This species has stems up to 2½ins. in height, slightly leafy and richly hairy. Numerous bracts with fine hairs occur and are shorter than the flowers, which are purple blue and about ½in. long. The leaves here are shorter and broader than in pumiliorum.

E. serpyllifolius (E. thymifolius) is well known in English gardens and does not require any description. It was found in 1829 by Viviani in the alpine regions of Dalmatia, and grows commonly on grassy limestone slopes in Bosnia, Montenegro and Serbia. There are two varieties of it, one with white flowers, "albiflora," and one with a minute tuft of very small linear

Digitized by Google

leaves, broad and smooth on the upper surface. These remain close together and are imbricate, just as are those of androsaces of the group Arelia. The flowers are hidden in the silvery foliage. It was discovered in 1861 by Owerin on the Erpeli Mountain in Darghestan, and is, therefore, the Eastern representative of the genus. Its place in the rockery is in a very dry situation, *e.g.*, in the crevice of a wall or in the moraine.

To the group where the flowers occur in heads belongs E. dalmaticus (E. caudatus), which was described by de Candolle in 1830. It is the most constant of all, keeping its characters better than any other. The leaves are about 2ins. long, hairy at their base, smooth near the top, and acute at both ends. The stems are partly ascending (4ins. to 6ins. high) and partly lying on the ground. The calyx is as long as broad and shorter than the corolla tube. The flowers are deep purple, almost an inch long, and number from three to eight on a head. The bracts are more or less smooth, rapidly contracted into a recurved point. It grows on limestone and rocky hills between Fiume and the Promina Mountain in Dalmatia, and is very abundant all along the coast.

Its nearest relative is E. serbicus, which differs in its upright habit. The stem is erect and varies from 7ins. to 8ins. in height. The leaves in this case are more ciliate and are narrower. The skin is richly foliate, almost glabrous, bearing blue-purple flowers a little over an inch long.

Then comes E. graminifolius, often confused with tenuifolius or dalmaticus. It has long linear leaves, very narrow and thin. The stem is variable in height, up to 8ins. Three to eight flowers occur in a head—purple-blue, rarely white, in colour. This plant covers the greatest area of any, growing from Sicily to the Transylvanian Alps. It is very variable in form, and permits of easy culture, as do the rest of the plants of this group.

E. niveus is the white form of it, found in 1892 by Beck in Mannaghetta on the Bosnian Alps, from 5,000ft. to 6,500ft. altitude. The leaves are shorter and broader. The stem is also short and thick, but notwithstanding, the plant is scattered over several districts. It is without doubt only a white variety. I am unable to speak of its reproduction, as I have never obtained seeds of it.

E. Kitaibelii has broader and shorter leaves, more or less linear. Larger heads of flowers occur here. They are deep lilac in colour. It grows on the Banat on chalk rocks exposed to the sun. It varies according to environmental conditions and differences in origin. The high alpine form is called alpinus by Wettstein; here the plant is a dense cushion of thin and short leaves bearing smaller flowers. In the Grecian Balkans grows a form with shiny hairy leaves and grey foliage, called mediterraneus by Wettstein.

Near to Kitaibelii is croaticus, with narrower lanceolate leaves, broad heads bearing two to five flowers, with oval bracts sometimes dentate. It grows on limestone Alps, in South Carinthia, Croatia, Bosnia and Dalmatia.

E. caricinus appears to be a middle form between croaticus and graminifolius. The flower heads are small (one to seven flowers), with hairy woolly bracts. The corolla is long and purple lilac in colour. It grows in Herzegovina and Montenegro on high limestone mountains.

E. stenophyllus is a very rare form which has very narrow leaves up to 4½ins. long. It is very hairy, like caricinus, but bears large flowers, eight to ten in a broad head. The bracts are broadly ovate. It seems to be an intermediate form between caricinus and tenuifolius, having the hairy leaves of the former and the large flower heads of the latter.

E. tenuifolius is generally confused with graminifolius, which is, indeed, a quite distinct species. The leaves are fairly long and narrow. The stem is variable in height up to 6ins. The flowers are bluish purple and of a moderate size. They occur ten to fifteen together in a large head (the largest of all). It grows on the Adriatic coast from Trieste to Montenegro, and on rather low rocky limestone hills.

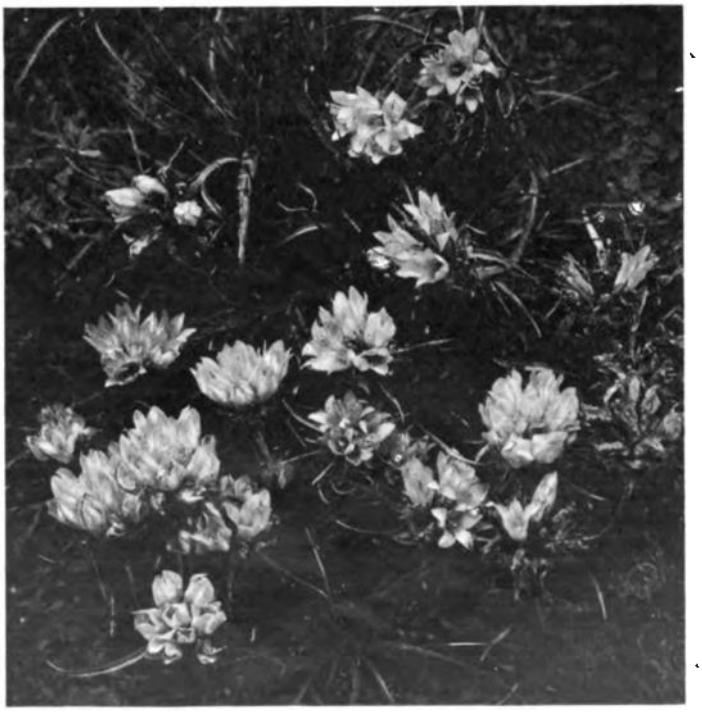
E. Wettsteinii from South Montenegro was recorded in 1891, but appears not to be in culture at the present time. The stem varies from 1in. to 4ins. in height. It is a humble-looking plant, the stems bearing a single—rarely two to three—flower, which is small and deep blue or purplish in colour.

There are several hybrids, of which Munbeckii (Kitaibelii) serpyllifolius, grown in 1910 at the Botanic Gardens at Wien, appears to be the one in cultivation. It is a small tufty plant with a thick root stock. The stem is long, bearing small leaves and deep violet flowers.

THE BEST KNOWN OF THE GENUS IN OUR GARDENS. E. SERPYLLIFOLIUS.

Edraianthus australis, bosniacus, elatus, pusillus and siculus seem to be only local forms and I have not found any descriptions of them.

[The above article by M. Correvon should be of invaluable help to gardeners, as he has done much to unravel the confusion which exists regarding these plants. The late Reginald Farrer graphically writes of these plants in the "English Rock Garden," and says: "One general picture paints the race—they all make rosettes of narrow leaves, from which radiate flopping stems bearing up bunches of purple campanulas at the end; and all, though rather lank in look, somehow, are bright and useful."—ED.]



EDRAIANTHUS DALMATICUS WITH FLOWERS IN HEADS.

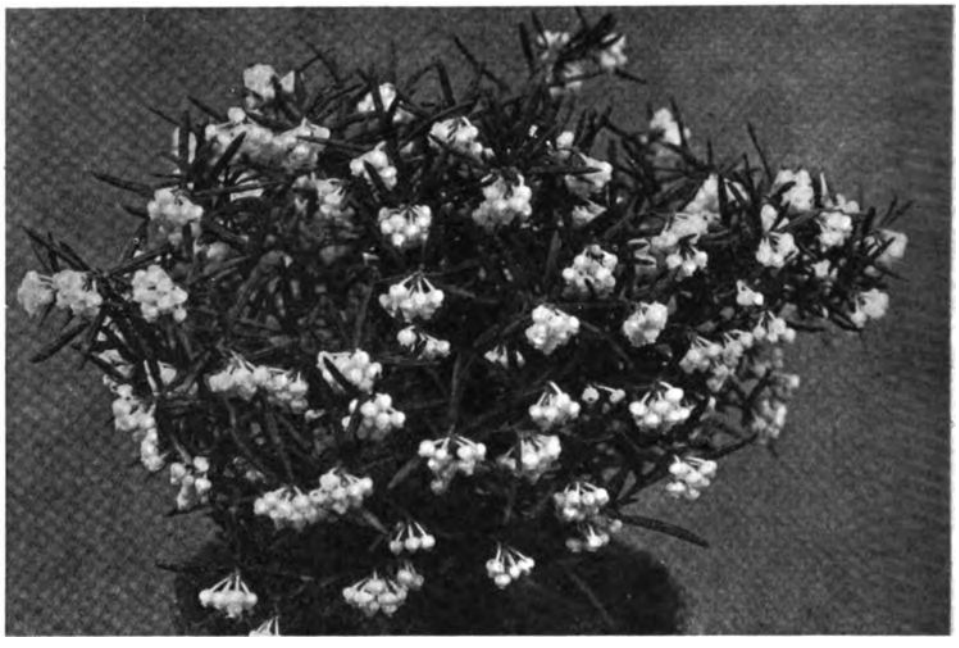
A DWARF SHRUB WHICH SHOULD BE MORE EXTENSIVELY GROWN

WE should like to bring to the notice of our readers a very charming and worthy little shrub, Andromeda polifolia, which is not often enough seen in our gardens. Technically, it is the only true Andromeda in existence, for those shrubs which are known in gardens under that name are really pieris, cassiope, leucothoë, enkianthus, etc. Heavily pruned of its species though the genus has been, yet the solitary species remaining is worthy of every consideration.

As will be seen from the illustration, it is a compact little shrub about 1ft. to 1½ft. high, with narrow leaves and compact clusters of snowy-white bells, which are produced in May.

It is a typical bog garden plant, and thrives best in damp peat. With the appearance of peat moss litter on the market the difficulty of obtaining peat in a suitable form has disappeared, for this latter when well broken up acts as an excellent substitute for the original article. In any case Andromeda polifolia must have moisture at its roots, and this must be conserved either by peat or a heavy mulching of leaf-mould.



ANDROMEDA POLIFOLIA, A VERY CHARMING LITTLE SHRUB.
This specimen was shown recently by Messrs. Cutbush, at Vincent Square.

It is a difficult plant to propagate by means of cuttings, but the roots can be divided and it is easily grown from seed. As in all ericaceous plants, seedlings must have perfect drainage, but peat litter passed through a sieve will satisfy all requirements.

SPRAYING MACHINES and their MAINTENANCE

BY A. J. MACSELF.

PROBABLY three out of four lawn-mowers are brought out just when the lawns are ready for first cutting, and some necessary repair is discovered which causes delay and annoyance. That may or may not be of serious consequence so far as the lawns are concerned, but when the same sort of thing happens with spraying equipment it is most highly probable that the results will be both serious and costly.

Delay in mowing a lawn will involve a deal of extra labour to rectify matters; but delay in spraying operations will most likely mean that the belated spraying will be futile, and the pests will have their fling.

It would be interesting to know how often it happens that a spraying machine is brought out for use when the wash is all mixed ready, the machine is filled, and the discovery made that it is not in working order. In eagerness to get on with the job, the machine is sent to the nearest tinker or, perhaps, to a cycle repairer or even a blacksmith, who, knowing nothing of the necessity for acid-proof washers and having no correct parts and fittings for such machines, just potters about with it and sends it back in a condition that means indifferent work, frequent stoppages, and a vast amount of irritation. All this means waste that cannot be afforded. A great proportion of the failures and disappointments of spraying might be traced to inefficient equipment, and the very first move in the season's campaign against garden and orchard pests should be to overhaul thoroughly every piece of the whole paraphernalia of the spraying apparatus and make good every defect.

There are sprayers that are never serviceable even at the outset. Goods that are simply made for sale at catch-penny prices cannot be overhauled to good purpose; but the best sprayers made cannot earn their money if they are treated with careless neglect.

A sprayer should never be put away uncleaned. Whether a caustic wash, a poisonous compound or a simple soft soap and quassia emulsion has been used, and whether the sprayer is to be put away for a couple of months or for twenty-four hours, it is unfair to the machine and extravagantly wasteful to put it away clogged and choked with adhesive emulsions and sediments. While the substances are still fresh and in suspension, a good flushing out with plain warm water will generally suffice to cleanse thoroughly the whole interior, while the exterior can be easily cleaned by sponging down and drying off with a duster. When put away uncleaned, acids will eat into plungers of pumps, washers and valves, and sediments will clog and corrode the threads of screws, nozzles, and all the vital parts of the machine.

The only thing to do where this has happened is to get paraffin into joints as well as possible, take the machine entirely to pieces, put every separate part to soak, and then thoroughly clean before reassembling.

Cleaning agents may comprise boiling water, washing soda, soft soap, or petrol, paraffin, or liquid ammonia; but where the chemicals that may have been used in the machine are not familiar and well understood, it is, perhaps, wiser to rely upon plain water and perseverance. Look carefully to washers and valves, and also to plungers of pumps. Wherever these are at all defective, replace with new. It is not economy to make do with any unsound washers. Be careful to get the right kind and the exact size required. Washers and plungers mean a great deal. I confess to a great preference for machines fitted with lead seatings. Leather, rubber and compositions are all right while new, and may retain efficiency a long time if kept scrupulously clean and frequently oiled or vaselined; but in a machine that has been neglected they soon perish.

There are machines on the market which are cleverly designed and well constructed, but which have so many gadgets and attachments, all of which are put on or sometimes inside the machine to ensure wonderful work, and provide a fluent representative or a ready pen with an excellent story to tell, but which all add to the difficulty of keeping the machine thoroughly cleaned, and make overhauling and readjustment a task for a gifted engineer.

Digitized by Google

The well made machine that is freest from intricacies, and which, above all, has its working parts outside rather than inside, and therefore easily accessible, is the machine for lasting service with a minimum of trouble. Some will say it is mere prejudice that objects to a machine with an interior pump. The other point of view is clarified when one happens to be using a machine in an orchard miles from a town, and the pump goes wrong. It is a comparatively simple matter when the pump is outside the machine to get it unscrewed and adjusted; but more than a bicycle satchel of tools is required to manipulate the interior mechanism of some machines I have handled.

The three-gallon knapsack sprayer is one of the most serviceable instruments ever made for the establishment of medium size. It is equal to the work of an orchard of bush and pyramid fruit trees, a few hundreds of bush fruits or roses, or anything up to an acre of potatoes. With a long lance of light bamboo a knapsack will reach to a fairly tall tree, and most wall fruits, except, of course, occasional trees of great age that have mounted to the chimney-pots. Whether the knapsack should be pneumatic or worked by an attached pump is really pretty much a matter of personal taste. I have not for some considerable time seen the tubular pneumatic machine that was carried horizontally and was charged with an ordinary bicycle foot pump. It was a good machine, rode comfortably in the small of the back, kept the fluid self-agitated with every step, left both hands free for directing the lance, and spared the operator carrying the weight of a fixed pump.

In fairness to the attached-pump machine—and as I hold no brief for maker or merchant I want to be fair to all—it must be remarked that it can be refilled and restarted without loss of time in charging with compressed air, and the charging, even with a good foot pump, is much harder work than the gentle working of the hand pump while spraying proceeds.

The real essentials are: efficiency of power to ensure forceful delivery, sufficient length of lance to give a good reach, and a nozzle so constructed that a fine mist-like spray can be evenly dispersed, with "choking" reduced to a minimum. Whatever kind of tap is used, it should be fixed at the base of the lance in such a manner that the hand holding the lance can instantaneously stop or restart the spray.

Hand machines for small gardens are made in endless variety. Some are trumpery and of less service than a syringe of fair quality. Some are of beautiful workmanship, quite the thing for the lady amateur; but for real utility the hand sprayer needs a capacity of about three quarts, should be pneumatic, and should be fitted with a 2ft. lance. They are only suitable for small work, and a longer lance is, consequently, unnecessary and unsuitable.

For a limited amount of high spraying there is nothing more suitable than the bucket sprayer, fitted with strainer, strong pump and a length of hose with long lance attached. The base of the ejector should be covered with gauze of non-corrosive metal alloy, and in the best makes the pump works a small agitator to keep the chemicals in suspension.

Syringes have their own special uses under glass, while a good syringe is quite competent for outdoor spraying on a small scale and will do far better work than too small a spraying machine. The ordinary perforated rose cap on cheap syringes is quite useless for purposes of application of insecticides and fungicides. The fine spray nozzle is essential. If used for caustic washes the operator should wear strong gloves, for back-wash is practically certain to burn unprotected hands.

The plunger will require repacking very frequently, but with a little care to bind with perfect evenness this is quite simply done and ensures comfortable working.

Of wheeled machines for more extensive work than can be economically done with a Knapsack, there are good and useful machines of varying style and capacity.

Where narrow gateways and paths have to be negotiated, a one-wheeled machine may prove to be most convenient. Many two-wheeled machines are made of quite narrow gauge to facilitate passing between nursery rows of young fruit trees. The one danger of very narrow two-wheeled carriages is that with the tank nearly full of liquid, and the necessity to turn a sharp bend on a sloping path, the whole vehicle is rather apt to capsize. Until I saw this happen I strongly insisted that the wheel axles should be kept as close in as possible, and that the tank should be long and narrow rather than short and wide. The sight of twenty gallons or more of caustic soda wash rushing over a grass bank on to a lawn convinced me that safety first would justify wider passage at intervals through plantations of bush fruits, etc., so that wheel carriages might be set wide enough to maintain balance. If one wants extra long lances to reach tall trees, or two lances that two operators may work, he should see that a pump strong enough to keep a good pressure is provided. The shape and pattern of the tank count for nothing if the pump is unequal to its work.

ANSWERS TO CORRESPONDENTS

TREES AND SHRUBS.

Conifers for Timber Purposes (C. K. B., Sedbergh).—Of the trees mentioned, Scots pine (P. sylvestris), Douglas fir (Pseudotsuga Douglasii) and spruce fir (Picea excelsa) are all good for timber purposes, conditions being equal. We recommend Douglas fir, since it is of fairly rapid growth and gives clean timber when well grown. A good species of spruce fir is the Sitka (Picea sitchensis). It is also a rapid grower and it thrives well in this country, being immune from rabbit attack. The Austrian pine (P. Laricio var. austriaca) is of little or no value from a timber point of view, but it may be mentioned that its cousin, the Corsican pine (P. Laricio) gives good results. The Corsican pine is being planted extensively in this country and thrives in a rather moist area. It is also immune from rabbits. It forms heartwood more slowly than in the case of Scots pine. As regards maturity, the Douglas will reach timber size before the others, while the spruces would probably take second place. To a large extent, the question of maturity and timber value depends on the soil and climatic conditions. The trees mentioned are all more or less accommodating, and we should suggest that it would be advisable for our correspondent to obtain information in his own locality as regards suitable species which have been already planted. We understand that Corsican and Austrian pine have been extensively planted at Wortley Hall.

Shrubs for a Dry Bank (H. B. E.).—In making new plantings of shrubs the ultimate height must be considered; but the width they will eventually grow to is not important. As more or less immediate effects are desired, hence the shrubs will number at least double the ultimate requirements, thinning from time to time as required. Pruning also plays an important part in any group of shrubs, for by this means many shrubs can be kept much below their normal size with oft-times improved effects. Berberis Aquifolium reaches a height of 5ft. to 6ft., but planted 1½ft. to 2ft. apart and kept to a height of 2ft. to 3ft. the plants are evergreen and also attractive in flower and fruit. Hypericum calycinum, 1½ft. to 2ft. high, planted 1ft. apart, soon forms a carpet of growths studded with yellow blossoms from June to September. Two of the best heaths flowering in winter and early spring are Erica carnea and E. darleyensis; the former is 9ins. or 10ins. high, and may be planted 1ft. apart; the latter, 1½ft. to 2ft. high, planting 18ins. apart. The cytisus will give plenty of flower in spring; those from 6ft., to 8ft. or 9ft. high are C. albus, C. Andreanus, C. præcox and C. scoparius; plant these 4ft. apart. Spartium junceum, 8ft. to 12ft. high, plant 6ft. apart. Quite a number of the late summer and autumn flowering spiræas thrive on banks. Planted about 2ft. apart, the following are showy: S. Douglasii, 4ft. to 6ft.; S. japonica, 3ft. to 5ft.; and numerous varieties, including alba, 2ft., and Anthony Waterer, 1½ft. to 2ft.; S. Margaritæ, 4ft. to 5ft.; S. Menziesii, 3ft. to 5ft.; and S. salicifolia, 4ft. to 6ft.

ROSE GARDEN.

Climbing Hybrid Tea Roses (H. A. W.).—Plant the following six varieties on the trellis at distances of 5ft. to 6ft. apart: Climbing varieties of Caroline Testout, Mme. Abel Chatenay, Richmond and Ophelia, with Frau Karl Druschki and Zéphyrine Drouhin. If our correspondent prefers flowers for the garden rather than cutting, substitute Grüss an Teplitz for Richmond.

THE GREENHOUSE.

Tomatoes Attacked (H. T., Dorset).—The tomatoes have been attacked by the fungus Phytophthora cryptogea, which enters the plant from the soil and is always worst when the weather is dull and the plants almost at a standstill. The means of avoiding it are to give ventilation very freely on all possible occasions, to avoid the least overwatering, and to sterilise the soil by watering it with ammoniated copper carbonate before planting the tomatoes.

Name of Plant (F. E. W.)—Primula elatior, "oxlip."

WITCHES' BROOMS ON THE COMMON GEAN

THE illustration on the right shows a peculiarity of growth of exceptional interest and one which is not uncommon.

The picture is of a cherry tree (Prunus Avium) growing in a garden in Perthshire. It is infected with a fungus, Exoascus deformans, which causes the characteristic deformities, ultimately forming what is now popularly known as a witch's broom. Secondary branches appear to have been attacked and have developed to extraordinary dimensions. These, containing the mycelium of the fungus, anastomose freely, and usually exhibit decided negative geotropism, while the basal portion is somewhat hypertrophied. Towards the base the branches of these witches' brooms are in many cases double the thickness of the branches from which they spring. Towards the apex, on the other hand, they become normal. In the case of this species only the leaves and the shoots are affected. There are many species of Exoascus, some attacking flowers and fruit, others, leaves and shoots. In all cases, however, the fungus causes hypertrophy of the part attacked. Very few species of tree appear to be immune, witches' brooms having been observed on beech, birch, elm, spruce, Scots pine, Weymouth pine (P. Strobus), larch, silver fir, robinia, prunus sp., poplar and others. The appearance of the broom does not enhance the natural beauty of the tree, but disfigures it to a certain extent, as is well shown. It is a feature which is to be found in different parts of the country, often occurring locally, in our woodlands, parks and policies, and readers may be able to recognise the damage since it has thus been brought to their notice. These abnormal growths are caused by various agencies, but in the majority of cases, the invading organism is generally found to be a fungus or insect. A small note dealing with an abnormal branch on Prunus Avium is to be found in the "Notes, Royal Botanic Garden, Edinburgh," No. XX, March, 1909, by Dr. A. W. Borthwick.

ONE OF NATURE'S FREAKS, THE WITCH'S BROOM.

G. C. TAYLOR.

THE DEPTH OF LILY BULBS

BY E. H. M. COX.

MANY people have complained about the poor showing which nomocharis are making in this country. Forrest, Farrer and Kingdon Ward have all remarked on the beauty of this Asiatic genus, so closely allied to the lilies. In China and Upper Burma they are vigorous growers, sending up strong stems often with several flowers to each stem, but in this country they have proved themselves to be decidedly intractable, with poor growth and sickly-looking flowers about a third of their proper size. Even at the Royal Botanic Gardens at Edinburgh, where their skill at growing Chinese plants is unrivalled, they have proved unsatisfactory.

A possible reason for their unenviable character is that the bulbs are not planted deep enough. Most collectors in the East have found the bulbs of Nomocharis pardanthina and of N. Farreri growing on an average at a depth below the surface equal to the height of the stem. I have commented on this fact in *Country Life*, and Kingdon Ward also notes it in his latest book, "The Romance of Plant Hunting." So far nomocharis have been grown usually in pans as a curiosity and in a few cases in rock gardens. In both cases conditions are not suitable for sufficient depth of planting. At Edinburgh, nomocharis have now been transplanted to a position where the soil is deep and where they can have freedom of action. It will be interesting to see the result this year.

I should think that even one year old bulbs should be planted in pots at a depth of 3–4ins. When germination is good it might be worth while testing the young bulbs at different depths at the end of their first year and seeing at what depth they give the best response.

It is not only in the case of nomocharis that the bulbs are found deep in the ground. Another deep-bulbed lily that Farrer and I found in Upper Burma was Lilium Thomsonianum, a Himalayan species. Here the bulb is a foot or more in the ground, and as it is always surrounded with little offset bulbules, it is reasonable to suppose that quite small bulbs, at any rate of this species, can be safely planted at a depth of 12ins. The bulb of Lilium polyphyllum is also found at a depth of a foot or more, while in the State of Washington, U.S.A., L. washingtonianum is found in cornfields beyond reach of ploughshares.

It is known that the bulbs of many of the South African liliaceæ are found at a great depth owing to absence of surface water, but this cannot be the reason in the case of Asiatic lilies. A possible explanation is that in areas affected by the monsoon or similar heavy rains the top surface, owing to the presence of quantities of detritus and rotting vegetation, becomes so sodden that to prevent its bulb from rotting the plant sends it down to a soil in which the drainage is more normal. I have always seen both nomocharis and lilies growing in Asia in pockets or on slopes with higher ground above them. This, of course, accounts for the depth of soil in which they grow.

An interesting problem is to find out the agency by which the plants send their bulbs down to this depth. Although my memory may be at fault, I cannot remember finding a single instance of pull roots such as are found on the crocus. Naturally, in country affected by very heavy rains there is constant movement of the upper surface of the soil and detritus will be deposited, but this cannot account for more than half an inch or an inch at the most.

I am certain that it would be worth while growing on yearling bulbs planted at a considerably greater depth than is done at the present time. This seems to be the best method of trying to approximate their natural condition, and certainly in the case of nomocharis there should be some chance of success.

THE USE OF GARDEN LABELS

BY GERALD HILLIER.

THE question of labels is undoubtedly a vexed one. Labels scattered all over the place do not, perhaps, enhance the appearance of one's garden. However, they are necessary adjuncts to the keen gardener. Quite satisfactory results can be achieved by the judicious use of the right label. The question then arises, which is the *right* label? There is, as everyone knows, a multitude of labels in various shapes and sizes now on the market. In the following notes I shall describe the labels I have tried, practically all of which have proved a success. No doubt I shall be "called over the coals" by readers who have discovered something better! Of course, in botanic gardens and nurseries it is absolutely necessary to employ a far greater number of labels than in a private garden. Perhaps the most difficult problem of labels arises in the case of the rock garden. For example, it is not advisable to allow one's friend to scramble over rocks on which plants are growing. It is therefore necessary to employ legible labels on the higher part of the garden so that anyone standing on the path can decipher them. For such a position oblong lead labels bolted to legs are often utilised. After the names of the plants have been stamped in the lead the labels are rubbed over with a rag smeared with turps, and polished with a dry scrubbing brush. Afterwards, the letters are filled in with white enamel paint, a pointed stick being used for this purpose. Such a label will last about three years.

For lower parts of the rock garden a lead label, somewhat after the same style but having no leg, may be employed. In Fig. 1 this label is depicted on the left-hand side. The bottom of this label is tapered and is thus easily stuck into the ground. For saxifrages, sedums, sempervivums, etc., growing near the path, the ideal label, in my estimation, is the oblong glazed one. This is green with the lettering in black, and is mounted on a leg. Two of these are shown in Fig. 1 in the centre. No. 2 in the same illustration is also a good label. Here white letters are mounted on a black background. Wooden labels must, of course, be used extensively, especially so in the case of plants that are only in flower for a very short period and then die down. In the latter case the labels should be "about turned" so that the tyro is not confused with other plants that may be growing in close proximity. As regards the lead labels described above, they may, of course, be any size and the leg any length. The nature of the plant must be considered.

FIG. 1.—VARIOUS TYPES OF LABELS WHICH ARE DESCRIBED ON THIS PAGE.

Wooden labels should first of all be painted white where the name is to appear. After the paint has dried the name of the plant should be printed with a gardeners' special label pencil. The latter is obtainable from all horticultural sundriesmen. Fig. 2 does not depict a floral cemetery, but a corner of the rock garden where very minute rare plants are growing. These labels are made of a celluloid substance and are flexible. Waterproof ink should be used for these labels if they are to be placed outdoors. For indoor purposes the name may be written on with a pencil. By this method the labels may be used indefinitely, as the names are easily erased with india-rubber.

Now let us consider the labelling of trees and shrubs. Here the famous Acme label is ideal. These labels are cast and will last a long time. They

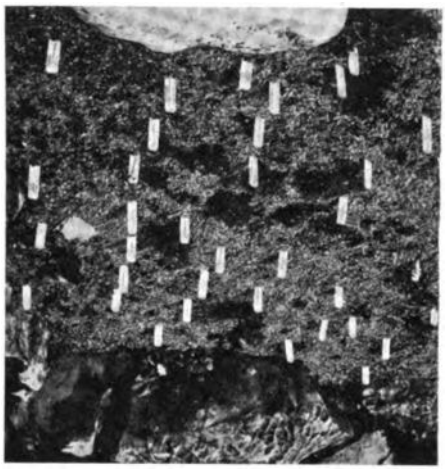

FIG. 2.—CELLULOID "IDENTIFICATION DISCS" FOR PLANTS.

are of various shapes and sizes, and may either be fixed on the plants or placed in the ground. The Acme labels will be found exceptionally useful for roses and fruit trees. One type of Acme label is shown in Fig. 3.

Let us, just for a moment, revert to Fig. 1 and look at the wooden label on the extreme right. At the top it will be seen that there are numbers. The first (75) indicates the seed packet number and the second one (05) that the seed was sown in 1905. Apart from these numbers it is always advisable to keep a log book. Many seeds take a long time to germinate, and it is exceedingly interesting to keep an account of a plant's life. Where exceptionally fine trees exist it is an advantage to have a descriptive label attached. At Kew many readers will have noticed the kind of label employed there. It is printed and enclosed in a small glazed frame.

A fine label, employed in a certain herbaceous ground, is, I consider, ideal.

FIG. 3.—A TYPICAL ACME LABEL.

Digitized by Google

The names of the plants are burnt on earthenware slips, and the latter are then dropped into iron supports. It is, however, doubtful whether these labels are made at the present time. If they are they will, no doubt, be somewhat dear. There is no question as to their lasting capabilities, because some I saw recently are said to have been in use for fifty years, and they look practically new.

In many establishments labels are wired on to deciduous trees and shrubs in winter, and when the flowering season arrives the labels are in many cases hidden. It is important to inspect labels wired on trees occasionally in order to prevent the wire from cutting into the bark.

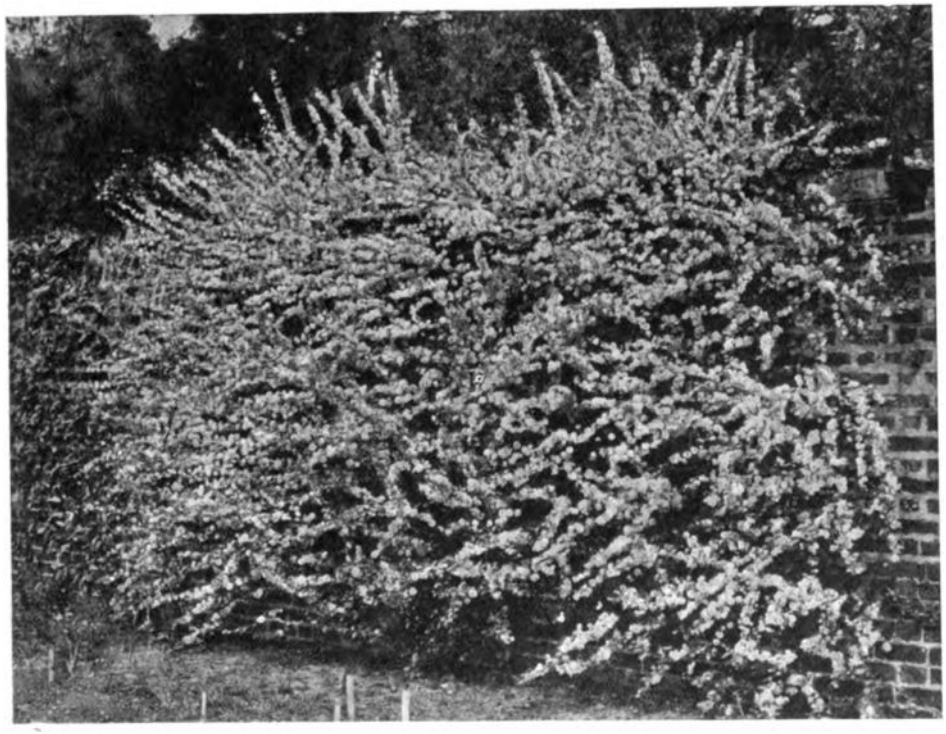
CORRESPONDENCE

THE SPURGE LAUREL.

I HAVE been taken to task so often for describing certain plants as rabbit-proof which have been found to suffer in other districts than that in which my experience has lain, that I hardly venture to add the evergreen spurge laurel (Daphne Laureola) to the list which I submitted recently. Bentham describes this species as doubtfully indigenous in southern Scotland, and I have little doubt that it was introduced to this district during the eighteenth century, when evergreen shrubs were scarce; but it is well established in our woods, spreading by self-sown seedlings, and I have never known it to be injured by roe deer, hares or rabbits. On the other hand. the deciduous D. Mezereum requires protection when first planted. Both species are now (March 17th) in full flower, the contrast between the richly coloured, fragrant bloom of the mezereon and the green, scentless flowers of the spurge laurel, being, in its way, one of the perplexing problems of spring. Hardly any winged insect life is abroad in early March; the spurge laurel hides its clusters of green flowers under its relatively large leaves, and there is no scent to betray their presence to insect visitors. Nevertheless, the plant produces plenty of black fruit, suggesting self-fertilisation. The late Lord Avebury shirked the question in his excellent treatise on British flowering plants. Of D. Mezereum he observes that "the flowers are sweet-scented, well supplied with nectar, and much visited by insects. Ludwig considered the flower to be sterile to its own pollen; Schulz, however, came to the opposite conclusion." Lord Avebury says nothing about the fertilisation of D. Laureola, but although I have detected traces of nectar in the narrow tube of the flower, I have never seen it visited by any insect.—HERBERT MAXWELL, *Monreith.*

THE PRUNING OF PRUNUS TRILOBA.

I HAVE been much interested in the article on the "Spring Treatment of Trees and Shrubs," in the issue of February 9th, page 67, by "A. O.," but I should fail in my duty to so lovely a flowering shrub as Prunus triloba if I made no protest against the recommendations to cut the year-old flowering shoots hard back in April. It is a cruel treatment, and I am sure that those who carry it out can never know what a beautiful shrub this is. The result of it is, in the case of a wall specimen, that an upright and down-straight effect is produced that is as stiff as the wall itself. I have had almost a life-long association with two wall specimens, and I fail to understand why these shoots, of commencing growth only, should be cut away without ever a chance of showing what they are when properly developed. They do not develop in one year, for in autumn there is a resting bud, as it were, at the apex, ready and waiting to continue growth the following year. This new growth is a stronger growth, but it is a continuation of the same shoot and should attain a length of perhaps 2ft. or more, covered with flowers from base to apex. In this there is something to admire; while a stubby and comparatively weak shoot of 8ins. or 9ins. long is nothing in comparison and does nothing to give beauty of form to the specimen. If my memory holds good, it is even the third extension that may be expected to give the fullest strength and finest magnificence. It is quite possible to prune so as to provide these fine shoots and also a succession for the time when it comes to cut them out. In this there is scope for art and skill in pruning, while cutting hard back is far too lamentably easy. I do not by any means condemn all hard pruning or cutting back, but it requires discretion, as anyone can see when a too hard-pruned shrub does escape the knife. It is quite contrary to Nature, which yields beauty only when helped in her own direction. I do not ask that anyone should take my word off-hand, but I do ask that those who have the opportunity should compare the world of difference in result between hard cutting back and pruning to maintain a fully developed and perfect shrub, suitable in size and extent to its position. Hard pruning, in the place of thinning and regulation and the removal of spent growth, is sometimes a great mistake, and I well remember the admiration shown by the late William Goldring of some fine effects which he found in the Cambridge Botanic Garden and accounted for by saying that with few men there was no time for pruning! THE GARDEN, some time ago, did a considerable service, I thought, by publishing on the cover a picture of neglected pear trees. It was an object lesson for the hard pruner, who forgets that he is not pruning a fruit tree. Neglected these trees were, no doubt, from a fruit-grower's point of view, and they would have been better, no doubt, for the regulating knife; but they had had the chance of their lives in showing how beautiful a pear tree can be. There are many rosaceous trees quite as fine if permitted to be so.—R. IRWIN LYNCH, *Chalston, Torquay.*



A WELL COVERED BUSH OF PRUNUS TRILOBA FL. PL.

THE TRIFLORUM SERIES OF RHODODENDRONS.

I HAVE read your article on the triflorum series of rhododendrons (page 168) with much interest, but I am afraid I do not agree with the remarks you make about R. triflorum itself, viz., that "its colour is a greeny yellow of no distinction, and it can be dismissed with no further description." Perhaps you are unaware that there are two forms of this species? The one, I quite agree, fits your description admirably, but the other, introduced at about the same time and to be found in Cornish gardens, has the most glorious bark of any rhododendron that I know; it is cinnamon-red in colour and peels freely, so that if you can get a bunch of plants with the evening sun shining through the loose bark you obtain a variety of colour in the autumn that is equal to many flowering plants.—LIONEL DE ROTHSCHILD.

[We do not quite understand Mr. Rothschild's statement that there are two forms of R. triflorum. According to the Royal Botanic Garden at Edinburgh there are no very distinct varieties of R. triflorum. No doubt, in good situations and climate, colouring of the stem takes place which is not so noticeable in districts which do not suit it. In any case it is the least hardy of the triflorum series.—ED.]

DAFFODILS AT WARLEY.

I SEE an illustration in THE GARDEN, February 23rd, of daffodils at Warley. It depicts some rather interesting daffodils. They are the Scotch form of the wild Lent lily, Narcisus Pseudo-narcissus var. scoticus. They were collected some twenty-five years ago in Scotland and a little colony planted by the birch trees. Among them came up two double flowers, which persisted every year until the war. I have not noticed since, but I will look out for them when the daffodils come into bloom this year.—E. WILLMOTT, *Warley*.

THE KING ALFRED DAFFODIL.

I WAS surprised to read in THE GARDEN of March 1st that the Rev. J. Jacob cannot succeed with this magnificent daffodil, as I had no idea it was difficult to grow. I have had bulbs of it now for nearly four seasons planted in deep loam with a chalk subsoil, and the blooms keep their size and stamina and promise well for the coming spring. Perhaps my success may be due to an annual top-dressing in February of dry wood ash (from indoor fires) covered over with burnt bonfire soil, which I give all bulbs indiscriminately. Messrs. Barr supplied me with the original bulbs, and they are increasing rapidly. I planted some in turf three seasons ago, and so far they are strong and vigorous. I see also in your contributor's notes on the "Amaryllis Belladonna" that he states that it is a native of the West Indies. It is one of the many natives of South Africa, and it is a never to be forgotten sight in October (the Cape spring) to see the Belladonnas growing under the oak trees, standing up among the fallen brown oak leaves, by the streams of the Paarl valley forty miles from Capetown.—(Mrs.) BAKER, *Cobham, Kent*.

MY experience of this daffodil is, on the whole, unsatisfactory. It is about the only one of the genus that looks unhappy here.

Beds of its seedlings, growing side by side with it, are every one of them in vigorous health, but King Alfred itself languishes.

I have tried lifting it every year, giving it different soil and aspect, all without avail.

I remember that Mr. Ernest Crosfield told me that he could not do it in his garden at Wrexham (where he then lived) nor in a plot he had in the south-west, nor at his place in Scotland; and I have letters now from the late Mrs. R. O. Backhouse, saying that she could do nothing with it. Yet some grow it and exhibit it in excellent form, notably the late Miss F. W. Currey.

It is most unfortunate that such an eminently beautiful flower should be so fastidious in its requirements.—F. HERBERT CHAPMAN, *Rye, Kent*.

LENTEN ROSES.

I NOTICE in your issue for March 1st "Somerset" says "The late Mr. Archer Hind of Newton Abbot worked for many years at improving the Lenten Rose and raised many fine varieties. What has become of them now?"

It may interest him to know that the late Mr. J. S. Tatey of Newton Abbot, well known to many gardeners of the old school and an intimate friend of Mr. Archer Hind, once told me that two cartloads of plants were given to Messrs. Barr and Sons of Covent Garden, from whom I had a few plants some years ago and they were certainly very fine. No doubt Messrs. Barr could throw some light on the subject.—CHARLES PRENTIS.

THE WELSH NATIONAL FLOWER.

IN response to Mr. Parker Woodward's request for information in THE GARDEN of March 15th, the Welsh for the leek is "Ceninen" and the daffodil "Ceninen Pedr," which means "Peter's leek." There is no doubt it was Peter's leek that was worn in ancient times, as it is worn on anniversaries of St. David's Day now in ever increasing numbers.—W. A. WATTS, *The Welsh Bulb Fields, St. Asaph*.

A REMARKABLE HYACINTH.

I ENCLOSE a photograph of a hyacinth grown in water from one of the bulbs obtained from Messrs. Robert Sydenham, Limited. It is a lovely pink, and four of the blooms are specially large and perfect, the fifth quite a nice bloom. The bulb was a very small one. It has been very greatly admired, and more than one authority on horticulture declared it has never been excelled.—(Mrs.) COALSTON, *Haddington, N.B.*

AN EXCEEDINGLY PROLIFIC HYACINTH.

RABBIT-PROOF PLANTS.

GAULTHERIA SHALLON appears to be quite rabbit-proof, at any rate, when well established. I make this reservation because anything shrubby that is newly planted appears to have an irresistible attraction for rabbits—possibly for the sake of experiment. Gaultheria is one of the best undershrubs for peaty or sandy soils and will endure a good deal of shade, even of Scotch pines. It should be a valuable thing in places where pheasants are preserved, as it affords ample shelter and a good deal of food when the abundant berries are ripe. In some places it grows almost too freely. Here in woodland (West Surrey) not far from the garden, it was planted on both sides of a wood path. About 50ft. from this is another path, nearly parallel. It has not only invaded the original path and entirely filled and smothered it, but has stretched out widely to right and left. Year after year we have watched its approach to the second walk. Now, about twenty years after the original planting it has reached this, and has been made to understand that it is not allowed to go farther. In fact it has been grubbed up for a yard or two from the path edge, and, from here and from adjoining regions of encroachment, something like five cartloads have been torn up and burnt. This sounds ruthless and wasteful, especially when much of it comes up with a mass of fibrous root that looks fit for planting elsewhere. But, although when it has taken hold it grows so freely, yet it is by no means an easy plant to establish. When I send it to friends I have to look about for small, compact seedlings, for they seem to be the only ones that will endure a journey and prosper. There are still places about the wood where it threatens too great an advance; here, also, it would have been checked but for the difficulty of affording the labour.—GERTRUDE JEKYLL.

ARUM LILIES IN INDIA.

HAVE you ever seen arum lilies growing literally in thousands? It is a beautiful sight. At Ootacamund on the Nilgiri Hills in Southern India they flourish in all swampy hollows during the winter months in wonderful luxuriance. Ootacamund is 8,000ft. above sea level and its minimum temperature in winter is about 40° Fahrenheit. There is no snow, but of an early morning the grass is often covered with hoar frost. This nips the lilies a bit at times, but on the whole they seem to withstand the cold very well.

These lovely flowers are much used in church decorations and are particularly in demand for weddings. The writer recollects gathering 400 lilies from one marshy spot to deck the church for a friend's wedding and yet to the general aspect the lilies there seemed in no way diminished in number. The arum lilies in Ootacamund are noted not only for their numbers, but for their magnitude also. Both flowers and leaves grow to an unusual size. Arum lilies flourish best in soft, oozy soil and along the river banks. They seem to need plenty of water, when cut and placed in vases, to keep them fresh, as they soak up a good deal of moisture.—I. C. P.

FRUIT-GROWING IN SMALL GARDENS.

I WAS greatly surprised at the omission of Apple Potts' Seedling from Mr. Hatton's probable list of sorts he would grow (page 145), as the variety in question is much grown in private gardens and well spoken of by reliable nurserymen. I have a long experience of the behaviour of this apple in gardens of various sizes and have, incidentally, taken prizes for it at the Royal Horticultural Society's Autumn Fruit Show. Without hesitation I would recommend it to any would-be planter wanting a really good September to October culinary apple. It is also quite excellent for dessert purposes and I have sent it to table as such on many occasions, when it has received marked acceptance. Potts' Seedling comes into bearing early, while it is a free and dependable cropper, whether grown as a bush or half-standard. The variety makes but little wood so it is peculiarly fitted for small gardens, where space has to be wisely allotted. Mr. Hatton mentions the variety Stirling Castle, an apple, to my thinking, spoiled by its beastly sourness, but there is nothing to say against its fruiting faculty. We grow Stirling Castle here as an espalier and Potts' Seedling as a half-standard.—C. T., *Ampthill Park*.

FORTHCOMING EVENTS.

April 1st.—Croydon Horticultural Society's Meeting.—Royal Caledonian Horticultural Society's Meeting.

April 5th.—Blackburn Horticultural Society's Meeting.

NOTES FROM CONTRIBUTORS

THE DELPHINIUM.

I AM sure that owners of naturally hot and dry gardens need not be deterred from the growing of this, the noblest of all perennials and probably possessed of the greatest future, by what Mr. Fraser (page 146) says about its need of water. The assertion that "delphiniums require a steady and ample supply of water all the summer through, especially during May, June and July," is certainly an over-statement. This reads as if they were thirstier than the run of perennials, which they surely are not. Their ancestors come from climates where the summer sun is fierce with little or no rain, and it has happened to me again and again to see my delphiniums in undiminished beauty while the plants on all sides of them were suffering grievously from drought. No doubt they accept water gratefully, but that "is another story." As to propagation, Mr. Fraser mentions division only. It is my experience that cuttings taken in March or as soon as the shoots are about 3ins. long give the best plants the third season. They root readily under a bell-glass without heat; a small bit of the old stock must be left on.

We are probably only at the beginning of developments of this fine flower. It is doubtful whether anything has been done in the way of artificial cross-breeding; unless I am mistaken, the best delphiniums of to-day are all the result of simple seed-selection. The structure of the flower makes it very difficult to manipulate for cross-fertilisation and they are quickly "set" by humble bees and other insect visitors. An obvious cross is that of our current florists' varieties with D. Belladonna. This I essayed year after year fruitlessly, owing to the infertility of Belladonna; but when I raised plants from seed of Belladonna offered some years ago by Messrs. Sutton, these in turn seeded in my garden and the cross which I had failed to make had evidently been effected by natural agencies, for the result was a series of plants running to 7ft. in height (Belladonna is comparatively dwarf) and from deep purples to the palest of silvery blues. And a great gain was that all the plants inherited Belladonna's glossy, dark green, much divided leaf, instead of the coarser and more "flannelly" leaf which I have always thought to be something of a defect in the florists' strain. Then came a tragedy. Of two long nursery beds containing some 800 selected plants, all but, literally, about a dozen were utterly blotted out by slugs in one memorable winter when even the wheat was largely devoured in this district. A friend living 200 miles away lost the entire stock of pale blues which I had given him from this same selection. And Nature has refused and my hand has failed to reproduce this cross. Last month I received from a relative resident in the highlands of British East Africa seed which is now growing well of a wild delphinium which varies from dark blue to white and is presumably hardy. I have not heard of anything in cross-breeding done with D. cardinale or Zalil.

In size of plant and flower we have perhaps reached the desirable limit or even exceeded it, if Mr. Jacob's "Hollyhock" delphiniums really approach hollyhocks in dimensions of spike and flower. I am, myself, quite contented, as to size, with such a variety as Alake. The ugly crowded spike, like a bulrush head or the woolly, cylindrical end of an old-fashioned bell-rope, is fast departing, but it is still well to avoid varieties catalogued as having "well furnished" spikes. The advance in colour has not, to my mind, kept abreast with the advance in stature and size of flower. There may be many, no doubt, to dispute the point with me, but I hold that many flowers have, each one, their own distinctive colour-note which it should be our main object to retain and enhance without adulteration. The distinctive and very valuable colour-note of the delphinium is *blue*. This may have an infinite range of shades and tones, varying by the subtlest degrees—which the eye learns to appreciate—from the deepest indigo to the very palest of "Cambridge" or "Eton" blue. Raisers should concentrate chiefly on these blues, aiming at pure selfs. I would not altogether exclude mauves and lilacs, but we are getting too many of these in washy or muddy quality, and over-much suffusion of pink and bronze in the blues. A weak point is the undue number of flowers with white centres. Some certainly give an effect of light, but they should be admitted sparingly or they give what I may rather vaguely call "a common look." Pure selfs are aristocrats in comparison. There is a great deficiency of very pale blue selfs, and the pale blue with dark bee is one of the most beautiful of all. There is only one true white known to me, Moerheimi, a quite lovely thing in its own way, but without the stateliness of the best florists' varieties. I agree with Mr. Jacob that we should be glad to see some of the Californian delphiniums, which apparently have a literature all to themselves, and some of the whites in particular. Moerheimi has a charming pale blue twin sister, identical with itself except in colour. Moerheimi will occasionally "sport" into a branch of Capri or into a single flower half white and half blue, but the converse seems never to happen. I once only found three seeds on Moerheimi which gave me three blue plants, one a fine thing of great stature and the richest deep blue colouring.

Buying delphiniums (and most things) from a catalogue without seeing them is mostly a disappointing business, and how can one judge of colour from print? In one list now before me I find sky blue, rich sky blue, richest sky blue, bright sky blue, dark sky blue, soft sky blue, brilliant sky blue, lovely sky blue, and not one of these epithets brings a definite colour to my mind's eye. But once, some three seasons ago, I bought of Messrs. Tucker of Oxford, from their mere description, a couple of plants of Blue Bird. The first bloom disappointed me, and I supposed I had once again been caught. The next summer I had been some while from home and returned to the full bloom of my delphiniums. Then one morning I found myself contemplating a new miracle of beauty, perfect in its tall, slender, tapering spires, perfect in the form and spacing of the flowers, and absolutely perfect in colour, a splendid, luminous small blue, the nearest to a true self I had ever dreamed of. Indeed, I can hardly imagine a more consummate thing, and I advise all who do not possess Blue Bird to hurry and get it. It is better all round in blue than Alake is in purple, and that is saying a good deal. But will someone give us a pure white Alake with black bee?—G. H. ENGLEHEART, *Dinton, Salisbury.*

GARDENS: OLD AND NEW.

THERE are some common features about all gardens—old and new. Seclusion, quiet, restfulness, are qualities alike possessed by the gardens of lordly palaces enclosed by lofty walls and the humble plot of the cottage adjoining the village street. For the pleasure to be derived from a garden is not to be measured by its stateliness or its style. A tiny pot such as almost anybody may cultivate may become "a lovesome thing." The garden of the poor may lay claim to possess similar delights to that of the rich, for flowers are no respecters of persons. "Flowers," says Ruskin, "seem intended for the solace of ordinary humanity; children love them; quiet, contented, ordinary people love them."

I may now tell you of one or two old gardens. Over three hundred years ago a writer described his own garden as "a little plot, void of all cost in keeping," and containing "a variety of simples," for you must know that old gardeners grew plants for salads and physic as well as for flowers. The people of those days believed very strongly in the value of herbs, and we, with our greater knowledge of medicine, cannot say that they were often wrong in their belief.

In a delightful essay written by Sir William Temple late in the seventeenth century he tells us that "in every garden four things are necessary to be provided for—flowers, fruit, shade and water, and whoever lays out a garden without all these must not pretend to any perfection. It ought to lie to the best part of the house, so as to be but like one of the rooms out of which you step into another." Now Sir William was an expert in garden making. He laid out his own garden at Moor Park according to the Dutch style then in fashion. It consisted of some six or eight acres, which he formed into grass plots and gravel walks relieved by fountains and statues.

Much might be said of old gardens; but coming to modern times, we notice that many changes have taken place, not only in the arrangement but in the cultivation of plants. Bedding-out or, as it is sometimes called, carpet-bedding was once very fashionable, and even now you will find this style of gardening is adopted by those who have plenty of space and can afford to change their plants from time to time to suit the varying seasons. But for the many, for those who love flowers for their own sake, for those who want "a garden of delight" to reproduce their beauty and the infinite variety of form and colour, it is best to follow the simple way of Nature. Ordinary people do not want their flower-beds to look like carpets. This style of gardening may be very well suited for public gardens where uniformity is required and where colour is one of the chief attractions. But you want a spot where you can walk or rest beneath the shade of an old wall or an overhanging tree. You want to gather a few flowers now and again without the fear of spoiling your carefully designed beds. It is well, therefore, to arrange your plants so that they may appear as naturalas possible.

I will conclude with a few general remarks which you must not forget if you wish to have success with your garden. To secure the best results there must be constant circulation of that great food carrier—water. Stagnant soil means unhealthy plants. For it is well to remember that nourishment is derived from the water itself, which gains its nutritive qualities from the ground and the air. A chalky bottom, if kept moist, is better than a clay bottom, because in the latter there is danger of the soil losing its sweetness.

With regard to the aspect of the garden, it is not always possible to secure what we would wish. But if fortune would have it so, let the slope be south-eastern, because, speaking generally, this is warmer and drier than any other. One more word: a garden should not be congested; it should contain just as much as it can grow, and no more. We may, indeed, be tempted to covet too much. Let us be satisfied with sufficient, for we shall then have both utility and beauty. —J. C. WRIGHT.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

VEGETABLES UNDER GLASS.

Cucumbers.—The plants from an early sowing are making headway and producing numerous fruits, and so they may be fed with liquid manure or Clay's Fertiliser. More seeds may now be sown to furnish a succession and take the place of plants that have ceased to be profitable. Seeds will germinate freely in a temperature of 60° to 65° Fahr., and the plants should be planted out before they become pot-bound. No difficulty ought to be experienced in growing cucumbers at this season. A moist, buoyant atmosphere should be maintained, a little air admitted from the top ventilators when the weather is warm, and the growths frequently stopped to encourage the fruits to develop. These are the principal factors in successful cultivation. White fly is often troublesome, and it is a pest that should be held in check, either by fumigation or spraying.

THE HARDY FRUIT GARDEN.

Spraying.—Now is a good time for spraying fruit trees with cleansing washes. Paraffin emulsion and lime sulphur may be safely tried on black currant bushes to combat the ravages of the mite which causes what is known as big bud. Leaf curl is one of the chief pests of peaches outside, and it should be dealt with in its early stages by spraying the trees with "Medela," an effective spray when properly used. For small gardens it is safer and cheaper to purchase the washes in small quantities as needed, and then strictly carry out the instructions given with the materials.

THE FLOWER GARDEN.

Gladioli constitute a charming race of showy flowers which are suitable for beds or borders and also for cutting purposes. A deep loamy soil is preferable, and it should be free from wire-worms, which are very partial to the young growth. The corms may be planted in rows 18ins. apart, 10ins. between the plants, and 3ins. or 4ins. deep. Where the soil is on the heavy side, a little sharp sand should be placed around each corm. Further plantings may be carried out till the end of May, thereby prolonging the flowering season.

Grass Seed.—It occasionally happens that bare places exist on the lawns, and that it is not always possible to turf them. Here, then, grass seed should be sown, and directly the soil is in a workable condition such work may be carried out. Bare patches should be pricked over with a fork, but where trees have been removed or beds dispensed with the soil will need levelling, making firm, and raking till a fine surface is obtained. Seed should then be sown and covered with a little fine soil. Roll the ground, and protect the seeds from birds.

THE KITCHEN GARDEN.

Broccoli are very valuable during the winter and spring months, and now is a suitable time to make the principal sowing. Sow the seeds thinly in lines 1ft. apart. The turnip fly is often troublesome to the young seedlings, but a sprinkling of soot or lime along the rows while the morning dew is still present is generally effective. To maintain a succession suitable varieties should be chosen, and even then a gap in the supply may occur, as so much depends on the season. The following I have found satisfactory: Early White or Favourite, Snow White or Leamington, Late Queen and Model, the latter being the best late variety I have grown.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Asparagus beds should be cleared of all manure and strawy material, which has been used as a mulch throughout the winter, and the beds made clean and trim.

Lettuce.—Young plants if fairly well advanced should be set out in lines 12ins. apart and 6ins. allowed between each plant in the lines on a south or west border. If severe weather follows place frame lights above the plants.

Parsley raised from seed sown in boxes three or four months ago and brought on under glass should be planted out in lines at the same distances as stated for lettuce. Parsley should be grown on well manured and deeply cultivated ground.

THE FLOWER GARDEN.

Carnations.—The border in which these plants are to grow should be deeply dug and if the soil is heavy a good dressing of old lime, sand and wood ashes should be applied. Fork this into the ground and tread to firm the soil. The surface should be well raked and the young plants set out in lines 12ins. apart and 8ins. allowed between each plant in the lines. The rooted layers should be lifted carefully so that the roots of each plant are kept intact.

Crambe cordifolia.—This hardy herbaceous plant, belonging to the seakale family, is very effective in large borders. Like the vegetable seakale it can be increased by root cuttings, which should be secured and inserted now in sandy soil.

Daisies.—Double red daisies when in flower make an attractive edging to a pathway. If young plants were raised from seed sown last year, these should be planted 6ins. apart in well firmed, but not over rich soil. Firefly is a very fine coloured variety.

Gypsophila elegans.—This hardy annual when in flower is very useful for decorative work. Seed may be sown about ½in. deep in prepared beds. Seedlings, if properly handled and carefully pricked out among pentstemons and antirrhinums, etc., in borders and beds, give quite a pleasing and graceful effect when in flower.

Lavender.—Young plants raised from seeds or cuttings should be set out on a west border in lines 12ins. apart and 4ins. or 6ins. between each plant in the lines. Pinch the growing tops of the plants when they are 3ins. or 4ins. high so as to obtain a bushy habit. If the plants are to remain permanently in the border they should be given more space, or every alternate one taken from the lines before they become crowded.

Mignonette should be grown on firm ground and where plenty of old lime and sand has been worked into the surface soil. The seed may be scattered over the bed or dropped into lines and covered with ½in. of fine soil. Mignonette does equally well with a south or western aspect.

FRUITS UNDER GLASS.

Peach Trees grown in unheated glass structures should now be in flower, and daily attention given to pollinating the blooms with a rabbit's tail. All watering necessary within the structure should be done in the early part of the day, so that everything is kept as dry as possible in case of frosts.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Veronica Hulkeana.—This beautiful New Zealand species, although hardy against a wall in the west, requires the shelter of a cool-house in the colder parts of the country. This veronica is easily propagated by means of cuttings inserted at this time, standing the cutting pots under a bell glass in a cool-house. Plants rooted now and grown steadily on during the summer in a cool greenhouse or cold frame, should make good flowering specimens for the stages the following April. Such plants grown on for another year will make fine specimens some 3ft. in height. These large plants require careful watering and treatment, because they are by no means easy to grow on. Thus, a batch of young plants should be raised each year.

Veronica speciosa, of which there are so many fine varieties, should be more generally grown for flowering during the autumn and early winter in the conservatory. Plants that were flowered in 48-sized pots last autumn, if potted on into 7in. or 8in. pots will make fine specimens for standing in the beds. If cuttings are put in at this time they root readily, and the resulting plants are very useful for the stages during the autumn. During the summer months these plants are best grown in cold frames, from which the lights can be removed. As the plants are free rooting they require ample supplies of water.

Buddleia asiatica.—This graceful plant with its fragrant white flowers is very useful for flowering during the winter. Stock can be increased by means of cuttings. The latter root in a close propagating case at this time and if the young plants are pinched once it will induce them to branch from the base. In their first year they make useful plants for the stages. After flowering they should be shortened back, and about this time shifted into 8in. or 9in. pots, in which they will make fine large specimens. If bushy plants are desired the strongest shoots should be stopped once. The plants, if allowed to grow without pinching, make long graceful shoots 8ft. to 10ft. in length. During the summer months the plants should be stood outdoors in a sunny, sheltered position.

Buddleia officinalis, is a bushy species, which succeeds under the same treatment as B. asiatica. It has lilac-coloured flowers with a yellow eye, which are strongly honey-scented, and for this reason the plant is worth growing. This plant flowers during the winter.

Pelargoniums of the show and regal types should be growing freely. Young plants should now be placed in their flowering pots, making the compost fairly firm, as this ensures good hard growth. The plants should be given a position in a cool, airy greenhouse. Pelargoniums are very subject to attacks by aphis, which should be prevented by frequent light fumigations. Where pelargoniums of the zonal type are grown for flowering during the winter, cuttings should now be rooted to provide the necessary stock. Plants used for this purpose during the winter, if cut back and started into growth, will make good plants for the conservatory towards the end of summer. The young plants intended for winter flowering should be potted on as they require it, and during the summer months stood outdoors in a sunny position, as it is important to have the wood well ripened.

PLANTS WHICH CAN BE PESTS

IN dealing with a subject with which most gardeners are only too familiar, two reservations must first be made, viz., we have to recognise the fact that a plant which is an ungovernable nuisance in one garden may be quite a respectable member of society in another. Also, it is essential, in common fairness to the malefactors presently to be dealt with, to bear in mind that those attributes which render a plant so undesirable in, say, the rock garden, may be, and often are, the very one's to prove most estimable elsewhere.

To proceed, it is but natural that those pest-plants from which one has personally suffered most deeply should receive first mention, hence I do not hesitate to give the place of honour to Meconopsis cambrica, which, once it gets entrenched in rock garden, steps or between flags, will resist expulsion to the extremity of its last and deepest root. Even so, the Welsh poppy is a fine woodland or wild garden plant, and the bronzy-buff form (not the double) is still better, but less enterprising.

Convolvulus althæoides (of the lists) is a plant of much charm and elegance, but woe be unto the rock gardener who once gets it firmly established. Its white, threadlike roots will wander under boulder and path and appear 6ft. away in the form of a rosette of green leaves which look like those of a young ragwort and they are an hundredfold more dangerous. C. althæoides is a worse terror than Kenilworth ivy (Linaria Cymbalaria), worse than any of the other pretty creeping toadflaxes, worse than L. repens, a peril for which I have a profound respect. Crucianella stylosa belongs also to this particular band of burrowing usurpers.

Epilobium nummularifolium is a surface creeper of too venturesome a disposition for association with decent company, and E. glabellum is only a little less lively. Helxine Solierolii we can suffer gladly since a timely snub, administered by frost, is sufficient to curb its career without destroying it outright. Of Arenaria balearica, which some say can only be eradicated by a frequent application of the scrubbing brush, we have never yet had enough, but Cotula squalida has long ago ceased to be a plant one would present to a dear friend. Veronica filifolia is a cheerful thing that will take undue advantage of a soft heart. Herniaria glabra, so useful as most of these little things are for carpeting, cannot be given a free run in the rock garden, and there are places which are better without Lysimachia nummularia.

Oxalis corniculata rubra is a plant of much charm, but a very "serpent in the grass" to the unwary. Very lovely also is O. obliqua, both in flower and foliage, yet what a nuisance it can be broadcasting its legions of bulblets and maze of underground runners in the most holy ground and that in an incredibly short time. An eruption of lesser celandine was never fraught with such peril as a single plant of O. obliqua in the wrong place. Some of the ornithogalums and alliums are also subjects which lie in wait for the unwary.

The acænas may sometimes offend by travelling beyond bounds, but they are easily removed. Their most troublesome possession is their burrs which, if allowed to ripen, have an annoying affection for one's clothing. But, happily, some of the most delightful species—A. Buchanani, for example—does not offend in that respect. In a cool place or bog Cardamine prætensis, fl. pl., can be really aggressive, forming wide, dense mats by layering its lower leaves. Albeit, one can not wholly ostracise such a particularly lovely plant, and it is after all, no more given to redundancy after its own peculiar fashion than are many of the astilbes and meadow-sweets after theirs. Erigeron mucronatus is a dangerously lively seeder in some gardens, and during the last year or so Apera arundinacea has shown symptoms which suggest that this beautiful grass needs careful watching where one does not desire a crop of hay.

Epilobium angustifolium and its pushful nature is well enough known to everyone who has ever tried to get rid of it, and in some places E. hirsutum may be nearly as bad. The red valerian (Centranthus rubra), splendid old plant as it is in a safe place, can be a heartbreaking plague where it is not wanted, and the same must be said of not a few of the knotweeds. Indeed, the whole of the genus Polygonum needs to be treated with caution, save the climber, P. baldschuanicum, and that beautiful trailer, P. vaccinifolium. The common or garden montbretia (Tritonia) must also be herded among the undesirables, and the gardener will be well advised who never plants an alstrœmeria, save where it may remain anchored to the bowels of the earth until the end of time. Hypericum calycinum (St. John's Wort) can be a "holy terror" where its presence is not desired, and, as for the shrubby spiræas, Douglasii, tomentosa and salicifolia, these can be vengeful invaders in a congenial soil. The last mentioned has usurped acres of moorland in some parts of Wales. Vinca major is a plant that can become an intolerable pest in shrubberies, walls and hedgerows, and Symphoricarpus vulgaris will never be planted by the gardener of discretion where its wiry, far-reaching suckers are likely to give trouble.

A. T. JOHNSON.

BOOK REVIEW

THE ROMANCE OF PLANT HUNTING

MR. KINGDON WARD in his latest book, "The Romance of Plant Hunting" (Arnold, 12s. 6d. net), has again dipped into the storehouse of his experiences in Yunnan, Upper Burma, and South-east Tibet. This book is full of interest and of information, useful both to the botanist and the horticulturist, but he is too much inclined to let his feelings run away with him.

He begins with a savage attack on nurserymen, who, he says, make capital at the expense of the poor plant collector. This attack is unfair and beside the point, for the collector sends the seed home to the members of the syndicate who finance the expedition. If this syndicate care to give seed to nurserymen to grow on and sell for profit, that is the syndicate's look out. The collector has been paid for goods he has delivered and there his liability ends.

It might be as well to point out that collectors would aid growers in this country if in their notes they would give fuller details as to the situation of the plant, the soil it grown in, how much it is sheltered from the wind, and so on. It is not sufficient to say that a plant comes from a rocky scree at an altitude of 1,300ft. A great deal of labour and ingenuity is wasted by growers owing to the paucity of information obtainable about plants.

One would wish that Mr. Ward was rather less free with his metaphors and similes. Here is a sample: "A fortnight's sunshine in genial March, and out they come, blithe as a kitten. Then in May, spent winter, with a wicked leer, turns on them as did the Normans on tricked Harold, and rends them. Whereupon, in high dudgeon, they miff off." It is all very "high-falutin," but it would have been more forceful if it had been a trifle more simple.

His book is so good and so full of interesting and useful matter that one could have wished that it had been a little better. We may hope that in the volume which he writes on his present expedition he may free himself from those little mannerisms which detract from the great charm of his previous books.

WINTER DISAPPEARS

I HAPPENED to be visiting my garden in Scotland when winter disappeared. The biting east wind and hard sunshine with frosty nights were gone in a flash and in their place came down that famous addition to our normal climate, what is called a Scotch mist, or more locally a harr; everything was soaking in moisture and the climatic conditions for growth were made more perfect by an occasional drizzle. Could anything be better for plants in early springtime? There was nothing boisterous or vulgar about the change; the moisture came gently with no splashing or tearing of the surface of the ground by a heavy downpour. The temperature remained cold, rarely above 45°, but at least it was consistent.

The ground absorbed the moisture like a dry sponge, and I could feel the change that was taking place in the plants. They were drinking their fill with every sign of enjoyment and in two days they had combed their hair and were spruced up ready to take the plunge into life and vigour whenever the temperature should rise a few degrees.

This winter has been abnormal with its persistent cold, hard weather, and so two days of moisture were bound to make a change; but almost every year there is a definite break, when life quickens of a sudden and plants strain at the leash. To my mind these few days of change are among the most interesting of the year, for there is nothing so fascinating as the final movement before the buds burst.

Those plants which I found reacting quickest to the change were deciduous berberis, spiræas, philadelphus, deutzias and cratægus. The berberis shot into leaf so fast that I could almost see their leaves expanding. One of the finest to my mind, but, unfortunately, rare because it strikes badly from cuttings, is B. kansuensis. It was introduced by Farrer from north-west China in 1914, and my plant was given to me by him in 1919 before we left for Burma. It is now 4½ft. high, a perfect-shaped bush with straight, slender shoots and villainous thorns, often an inch in length. The leaves are oval, up to 2ins. long, while the flowers are clear primrose yellow bells. So far I have not seen the fruit. It is no exaggeration to say that the buds were tight on the Friday night, while on the Monday afternoon they had burst and ¾in. of leaf was visible.

This plant now grows at the rate of 12ins. to 18ins. a year with no signs of stopping. Farrer left no description that I can find and I am unable to tell its ultimate height, but to my mind it is easily the best of the deciduous berberis. Probably a number of plants are scattered throughout the country, but are, perhaps, unknown by name. Wherever it is found it should be treasured.

One of the most remarkable of winter plants is Viburnum fragrans, which has been rather left in the lurch by the supposed superiorities of V. Carlesii. I find that V. fragrans is an infinitely better grower with me than V. Carlesii. It is true that in its young stage it does not flower freely, but once it is over 4ft. it is in continuous bloom from the New Year to the end of March. Here again I have one of Farrer's original plants, now a giant 6ft. high and 4ft. through. It is obviously going to grow into a bush equal to those he found near Siku, 14ft. high and as much in diameter. Night after night it has stood ten or more degrees of frost without turning a hair or losing a flower. Suddenly, with the coming of the mist it burst into leaf, yellow at first, but later they will turn into that rich, velvety green which makes its foliage so striking. I, personally, will back this plant any day against V. Carlesii, of which it is a close relation.

A third example should be given of the change which two days of air saturated with moisture can accomplish. Spiræa sorbifolia is a curious-looking Chinese species, of rather exotic appearance. In this case the first leaves always come at the very tips of last years' shoots, where they look like miniature feather dusters. These suddenly appeared one night; the transition was instantaneous; there was no delicate tip of a shoot creeping out to test the weather; they burst.

The amount of damage during this winter varies in different parts of the country. From reports which we have received it seems likely that the west and south coast has suffered more severely than the north and east. In my garden practically nothing has been seriously damaged. Buddleia Colvilei is, perhaps, a doubtful starter, but it was only planted last autumn and has had no chance of becoming established. It is no doubt true that after plants have been cut for three or four years they will find their own level and willingly accommodate themselves to new climatic conditions. I have another Buddleia which is five years old. The first year it was cut to the ground, the second to within 6ins., the third to 2ft. and so on. This year it is 6ft. high and has only been touched at the very points of its shoots.

Bulbs are backward, but their growth is strong and healthy and they have obviously plenty of flower in store. But this winter has ripened all plants in a way which they have not been blessed with for many a year and there is little doubt that this is going to be a mighty gardening season, if only we could be certain that this is the real spring and not the imitation variety which drops back into winter in April. What is wanted is a warm and moderately wet spring and early summer with a pleasantly hot late summer and autumn. E. H. M. C.

BORDER CARNATIONS

AT the present day I am afraid that the general cultivation of border carnations has suffered somewhat owing to the popularity of the beautiful perpetual-flowering section. The latter is largely grown for a supply of cut blooms: the border carnation, with its limited period of flowering, suffering by comparison with the more perpetual-flowering race. The border carnation will, however, always be popular with cultivators, who admire the finely formed flowers and wide range of delicate and refined colouring. Even at the present day many people do not attempt to grow them because they imagine they are not hardy and require the shelter of cold frames during the winter. This is a mistake, as the plants are perfectly hardy, except perhaps in very damp and low-lying situations where the soil is cold and heavy. In fact, my experience of them from the north of Scotland down to Devonshire is that much better results are obtained by planting them out during the autumn rather than wintering them in cold frames. Taking it for granted that one has a healthy stock of plants, I will deal briefly with their cultivation from the time of layering, which is the method of propagation. Plants should be ready for layering towards the end of July or beginning of August, or just about the time they finish flowering. In any case it is essential that layering should be done as soon as possible, so that well rooted plants are ready for planting out during September and October, thus allowing them to become well established before winter sets in. The operation of layering is quite simple, although some small details are important for success. If we take a healthy, well grown plant with plenty of "grass," the weaker shoots should be cut out, and the shoots retained for layering should have all the lower leaves stripped off. The soil should then be drawn away from the plant, leaving a depression into which should be placed some prepared soil—leaf-soil and sand being excellent for this purpose. This prepared soil should not be mounded up as most writers advise, but kept level with the surface of the bed. When mounded up, it is very apt to dry out, and birds often prove troublesome by scratching it away. If done as I suggest, no trouble will arise in that respect. When the shoots are layered the soil drawn away from the plants should be replaced on the top of the prepared compost. A thin-bladed, sharp knife is essential for successful layering. Having stripped off sufficient leaves, the stem should be split into a tongue, starting at the base of a joint and splitting the stem upwards to about half way between the two joints. The shoots should then be laid out horizontally on the prepared soil, with the same movement carefully raising the top of the shoot into an upright position, thus opening out the tongue. This should be carefully pressed into the soil and the shoot pegged down, and soil that was drawn away from the plant replaced, pressing it firmly round the layered shoot to keep it in position. The operation is then complete, and in about six weeks time the layered shoots should be well rooted. Some growers use a thin-bladed, double-edged knife for layering, inserting it midway between two joints, running it downwards and out below the lower joint; but the method used is immaterial so long as the work is cleanly and quickly done, and a little practice soon renders one quite expert. I may say here that a kneeling pad is essential for comfort and quickness of working.

The beds or borders should, if possible, be prepared some weeks before planting takes place. As carnations enjoy a good, sound, medium loam, light sandy soils should be improved by the addition of good loam and well rotted cow manure. On the other hand, soils that are over-heavy and cold may be improved by drainage and the addition of gritty material; here stable manure should be used. In low, wet situations it may be necessary to raise the beds a little above the surrounding level. The beds or borders should be thoroughly cultivated, and when finished a dusting of lime forked into the surface of the beds. I consider that lime is essential for the well-being of carnations.

A TYPICAL SELF-COLOURED CARNATION, BOOKHAM YELLOW.

Given well rooted layers, planting should start about the end of September and may continue into November, but the sooner it is done so much the better for the plants, as it gives them a good chance to become well established before the winter. Before planting, the beds should be made fairly firm. The young plants should be planted well down, and it may be necessary in some cases to remove some of the lower leaves, for if buried they may rot and set up decay. Once planted, no further care is necessary beyond firming plants that may have been lifted by frost. Hoeing occasionally is, of course, necessary. The plants should be neatly staked when the flower-stems are pushing up. Thin bamboo canes are very suitable; there are also now quite a number of good wire stakes on the market. Tying should be carefully done, so that the tie will rise with the growing shoot. It is wise to pot up some spare plants and winter them in cold frames, or I have found it a good plan to line them out in the reserve garden, placing some leaf-soil round the roots. Such plants make large masses of roots, and will transplant well during the spring. When necessary these plants may be used to replace losses that may have occurred in the beds.

CULTIVATION IN POTS.—If it is desired to grow these carnations in pots, the layers should be placed in sixty-sized pots during October, standing them in cold frames during the winter. They should be kept somewhat close for a week or so until they get a hold at the root. Afterwards they should be given plenty of air on all favourable occasions, removing the lights altogether during fine days. Early in March the plants should be placed in their flowering pots. One plant may be placed in a 6in. pot, two in an 8in. and three in a 9in. pot. The potting compost should consist of a good medium loam that has been stacked with some well rotted cow manure for six months. I do not favour the use of leaf-soil except in the case of very heavy loams, while old mortar rubble may be used with advantage in place of sand. The plants should be returned to the frames, removing the lights altogether when

Digitized by Google

they have got well hold of the soil. They may be left outdoors until the buds show signs of colour, when they should be removed to a cool, airy greenhouse. If it is desired to have the plants in flower earlier, they may be placed in the house when they are put in their flowering pots, remembering always that they must have perfectly cool treatment during all stages of their cultivation. Most varieties require partial disbudding, but the extent to which this is carried out depends entirely on the purpose for which they are required, *e.g.*, whether for exhibition or for ordinary decorative work, or just for making a display in the garden.

Carnations are readily raised from seed, and even if they do not give any flowers of first-rate quality, there is much interest in watching them develop. They are also strong and robust in growth, and provide a wealth of varied and beautiful flowers for cutting. In the first place, seed should be procured from a reliable source and sown indoors in a temperature of about 55° during March or April. When the young seedlings are fit to handle they should be pricked off 3ins. apart in seed boxes. They should be grown in cold frames until they are ready for planting out. This will vary according to the time they were sown and the progress made. Towards the end of June or beginning of July they should be strong plants ready to pot out in the positions prepared for them, where they will require little attention beyong hoeing and weeding, and possibly watering during spells of dry weather.

Carnations, in common with most plants, suffer from various insect pests and fungoid diseases. Red spider is seldom troublesome outdoors, but often attacks them under glass. However, the use of the syringe should prevent this.

Thrips prove troublesome both indoors and out, and should be prevented by spraying with a nicotine insecticide. Aphis can be dealt with in the same way, or indoors by fumigation. Carnation maggot (the larva of Hylemyia nigrescens) often causes much damage, usually among seedling plants and varieties with strong, soft-growing shoots. The only remedy is to examine the plants carefully and pick out the maggots with a needle.

THE BRILLIANT COLOURED KELSO.

CARNATION STEERFORTH, MAROON AND WHITE.

Eelworm is a common pest, and causes what is generally known as gouty stem. The infested stem just above the ground line becomes swollen and puffy, while the foliage shows pale yellowish patches. Infested plants should be carefully pulled up and burned. Wireworms often prove troublesome, and when preparing the soil a sharp look-out should be kept for them. They may also be trapped by inserting carrots in the ground, examining them regularly and destroying the wireworms.

Mildew can be prevented or cured by spraying with liver of sulphur, using 1 oz. to 3 gallons of water. Rust usually only proves troublesome indoors during the winter months, and the only preventive is to maintain a dry, buoyant atmosphere and no moisture on the foliage. Spraying only provides the best conditions for the spread of this disease. For black spot, spray with liver of sulphur as advised for mildew. All the pests and diseases are fully dealt with in various hand-books, but most of them can be more or less prevented by clean, careful cultivation, and I believe much trouble is caused by the indiscriminate use of artificial manures. If used at all, they should be applied with great care.

For outdoor work good strong-growing varieties should be used. It generally proves misleading to give lists of so-called best varieties, as one is never sure what any particular variety will do in any or all localities. However, the following short list includes some of the best in their various colours: Belladonna, coral red; Bookham Rose, Annie Laurie and Rosetta, rose; Prairie Belle, Elaine and White Fox, white; The Grey Douglas (heliotrope), the best in this colour and a strong grower; Fujiyama, red; The King, Gordon Douglas and Hercules, crimson; Border Yellow, yellow; Effie Deans, apricot; and Melanie, orange.

FANCIES.—Linkman, Pasquin, Steerforth, Cordelia, Sweet Anne Page and Kelso. In addition there is the set of clove-scented varieties raised by Mr. James Douglas of Edenside, Bookham, being varieties with the old crimson clove colour but much stronger-growing plants. There is now quite a range of colours in this sweetly scented class, including white, various shades of pink, scarlet, purple, and maroon. J. COUTTS.

VIBURNUMS—THE ASIATIC SPECIES

(*Continued from page* 205.)

AS garden plants the Asiatic viburnums are, generally speaking, more valuable for ornamental planting than the eastern North American species. This is due largely to climatic conditions, as we know from the descriptions of writers and visitors to the States, how useful the native species are for ornamental planting in New England. In flower, and particularly in fruit, the American viburnums are attractive shrubs and small trees.

It is now twenty-three or twenty-four years since Mr. Wilson sent home the first of his viburnum seeds. Collecting on behalf of Messrs. J. Veitch in 1900 and 1901, VV. Henryi, rhytidophyllum and utile of the evergreens and VV. betulifolium, lobophyllum and Veitchii of the deciduous species were among the first arrivals. With some twenty years' experience of their behaviour in the varying conditions of the British climate and soil it is possible to form some estimate of their value as garden plants.

The deciduous species on the whole fruit better than those from North America, VV. betulifolium, dasyanthum and lobophyllum in particular are usually heavily laden with rich red fruits each autumn. As one might expect, the evergreen species are happiest in the more genial climate of the south and west. Afforded some shelter, however, and as wall shrubs VV. Henryi, rhytidophyllum and others promise to be conspicuous permanent additions to cultivated evergreens.

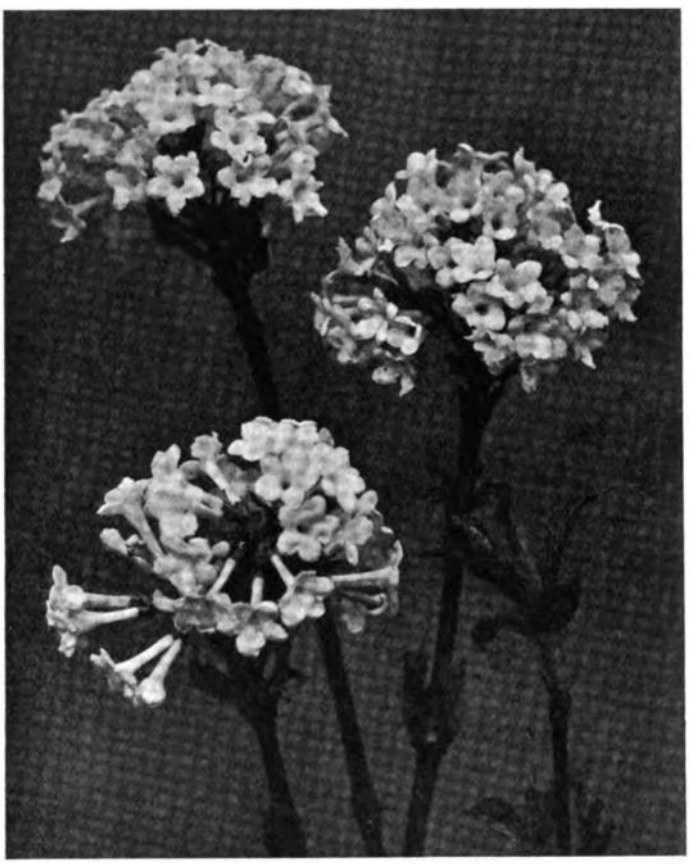
It is among the Asiatic species that we have the most valuable flowering bush in the family, V. tomentosum var. plicatum. It is the sterile form of the species, the flowers forming a globose inflorescence, hence the popular name of the Japanese Snowball Tree. With its rounded heads of waxy blossoms, pale pink at first, changing to white, V. Carlesii from Korea, with its delicious fragrance, is the gem of the genus. V. fragrans one of the best known of the late Mr. Reginald Farrer's introductions adds a valuable winter and early spring flowering shrub to our gardens.

Among the species on the borderland of hardiness at Kew and which we find necessary to plant against sheltered walls or cultivate in pots, are several useful shrubs. A well grown plant of V. macrocephalum, with its large heads of sterile flowers, the largest of the genus, is a beautiful sight in May. Others worthy of note are VV. japonicum and odoratissimum, which is the V. Awabuki of the Botanical Magazine tab. 456. The small-leaved V. Harryanum which Mr. Wilson introduced in 1904 is a very distinct shrub and not at all like any other species of viburnum. It is of bushy habit but only suitable for a very snug corner. Another distinct addition is V. Davidii, a low-growing attractive evergreen shrub 1½ft. to 2ft. high, with leathery leaves up to 6ins. long and half as wide. Introduced by Mr. Wilson in 1904 it thrives in partial shade and has showy blue fruits.

V. betulifolium is one of the most attractive in fruit of the numerous deciduous species from Central and Western China. First introduced by Mr. Wilson in 1901, we have bushes raised from seeds collected by him in Western Hupeh during 1907 and from Western Szechuan in 1908 and 1910. The number of districts where seeds were collected suggests that it is a common bush in the thickets and open woodland. It forms an attractive bush 8ft. to 10ft. high, with ovate leaves coarsely toothed towards the apex. The corymbs of white flowers up to 4ins. across are of no special merit, but give place to an abundance of fruits. In autumn V. betulifolium attracts very considerable attention when the branches are laden with clusters of brilliant scarlet fruits.

For some years following its first introduction to British gardens in 1902 two plants were in cultivation as V. Carlesii. It can be readily understood how quickly the dainty wax-like blossoms and delicious fragrance attracted attention and large orders were sent to Japan for plants. There, unfortunately, the plant we now know as V. bitchiuense, a native of the mountains in the province of Bitchiu, in Western Japan, and the Korean plant, true V. Carlesii, were identified by the Japanese botanist, Makino, as the same species. Being more readily propagated, the Japanese plant predominated among the earlier consignments of plants, resulting in much disappointment among purchasers. For a time it became known in our gardens as the inferior V. Carlesii. The habit of V. bitchiuense is much more robust and open. In the west there are plants 12ft. high. The corymb of flowers is smaller and loose, they are white tinted with pink and less fragrant than the true V. Carlesii.

Among the whole family of viburnums none equal in charm and fragrance the true V. Carlesii. It is a plant for the



VIBURNUM FRAGRANS, WHICH FLOWERS, FROST OR NO FROST, FROM THE NEW YEAR TO MARCH.

garden of choice shrubs where the bushes will receive the little extra attention required for their successful cultivation. Being a native of Korea we, naturally, expect the plants to benefit from a little shelter in spring. It is a deciduous shrub of close rounded habit, 3ft. or more in height and more in diameter. The wax-like flowers are at first tinted with pink then white and are powerfully fragrant. For this species we find a little peat or leaf-mould mixed with a well drained loamy soil beneficial.

From the Himalayas we have V. cotinifolium, a robust bush up to 10ft. or more in height, resembling in growth and leaf V. Lantana. The corymbs of white flowers are attractive in May; later, the red fruits are ornamental and change to black when ripe.

V. coriaceum (syn. V. cylindricum) is a distinct evergreen shrub or tree with a very wide geographical range, being found in China, the Himalayas and Java. It is variously described as a shrub 10ft. to 15ft. high, to a tree 40ft. to 50ft. in height. With a plant of such varying distribution and habit it is not surprising to find plants of varying degrees of hardiness. I have seen specimens of Chinese origin making splendid progress in Cornish and Sussex gardens. The attractive glossy leaves have the peculiar character of assuming a whitish hue when rubbed, due to a curious waxy surface. The flowering season is late summer, the cream white blossoms with purple anthers are freely borne on a flattish inflorescence 3ins. to 5ins. across. The fruits are black.

Digitized by Google

V. dasyanthum is a free-growing deciduous shrub introduced by Mr. Wilson in 1907. The dark green leaves are up to 5ins. long and half as wide on gracefully arching branches, the bushes 8ft. or 9ft. high. The corymbs of small white flowers in early summer are of no particular merit. It is in autumn when the branches are gay with red fruits that this viburnum is a valuable asset in the shrubbery, border and pleasure grounds.

V. dilatatum a native of Japan, China and Korea, is an attractive species, forming a large shapely shrub 8ft. or more in height, gay with flat clusters of white flowers in late May and June.

V. fragrans is to be found in the Kew Herbarium as a specimen named by Bunge, with the date 1835. Most of the plants cultivated in our gardens were raised from seed, or are the progeny of the seeds collected by the late Mr. Reginald Farrer in 1914. It had, however, been first introduced several years previously by the late Mr. William Purdom from Messrs. Veitch. One o. these, Purdom 689 or 690, the largest bush I have seen, is growing in Mr. Gerald Loder's garden at Wakehurst Place, Sussex. It was obtained from Coombe Wood by Mr. Loder and is a splendid specimen bush 8ft. or 9ft. in height and as much in diameter.

A MOST USEFUL AND CHOICE EVERGREEN SHRUB, V. TOMENTOSUM VAR. MARIESII.

Smiles were on the faces of some of us when reading the adjectival descriptions of the plant in the notes sent home with the seeds by Mr. Farrer. Here are extracts: "a most glorious shrub attaining 8ft. in height . . . profuse trusses of pearl-pink flowers in spring like lilac deliciously smelling of heliotrope . . . rare as a wild plant but generally cultivated in Kansu for its loveliness and fragrance."

Though one would hesitate to place V. fragrans on a par with V. Carlesii at its best as a choice shrub, the Kansu plant is easy to grow, while some special care and attention should be lavished on the Korean species to obtain good results. V. fragrans is as easy to root from cuttings as fuchsias from about midsummer onwards. In the gardens of the south and west with their mild climate the bushes flower more or less throughout the winter, some blooms even attempting to open before the last leaves fall from the branches. Fortunately, unless frosts are severe they appear to do little harm to the flowers, though the young leaves unfolding in spring are readily damaged. Mr. Farrer described the fruits as glossy scarlet and well flavoured.

V. Henryi was collected by Mr. Wilson during three of his journeys, 1901, 1907 and 1910. It is an evergreen shrub of erect habit, and quite a hardy plant in sheltered positions, its greatest enemy being wind. The flowers are showy in June though the value of the shrubs is greatest in autumn when laden with panicles of red fruits.

V. lobophyllum is another of the free-fruiting deciduous species introduced by Mr. Wilson, which thrive at Kew. It is an attractive bush 8ft. to 10ft. high with corymbs of white flowers 3ins. to 4ins. across, followed by red fruits.

V. rhytidophyllum was one of the first plants to attract attention during the earlier years of Mr. Wilson's journeys in China. From seeds received in 1900 Messrs. James Veitch frequently exhibited attractive evergreen plants in tubs of this species. A specimen in fruit was awarded a first class certificate by the Royal Horticultural Society in September, 1907. Wind again is worse than frost with this viburnum, as, blowing through the plants, it causes the leaves to hang down in winter giving a most unhappy look to the plants. Hence it is desirable to plant this striking shrub, which Mr. Wilson describes as the hardiest evergreen Chinese viburnum in the Arnold Arboretum, in sheltered positions. The best plant at Kew is on a south wall. The average height is said to be 8ft. to 10ft., but against a wall it grows much higher.

V. Sargenti is the Asiatic representative of the Opulus section, but does not thrive so well with us as the European species. V. Sieboldii is a Japanese species forming a sturdy, deciduous bush with us 7ft. or 8ft. high, but in Japan sometimes attaining a height of 30ft.

The most useful of all the Asiatic viburnums for our borders and pleasure grounds are the several forms or varieties of V. tomentosum. They are natives of western China and Japan. A deciduous shrub of bushy habit, the unripened ends of the young twigs are sometimes damaged by frost, especially in the variety Mariesii, but the plants quickly recover in spring. The forms with fertile and sterile flowers are surpassed in floral beauty by var. plicatum, of which there are two forms with wholly sterile flowers, grandiflorum, the larger flowered, as

PLESH, ONE OF THE MOST POPULAR OF THE FAMILY, ALTHOUGH NOT SUCH A SATISFACTORY GROWER AS V. FRAGRANS.

Google

the name suggests, and rotundifolium, a smaller and slightly earlier-flowering bush.

V. utile, an evergreen species of upright slender habit thrives best in sheltered positions. The inflorescences of closely packed blossoms are showy during May. Another deciduous species first introduced by Mr. Wilson in 1901 is V. Veitchi. It is a vigorous shrub 8ft. to 10ft. high with handsome foliage resembling V. Lantana, white flowers and red fruits, changing to black when ripe.

Numerous other species might be mentioned, but sufficient has been written to indicate the wealth of interesting and useful shrubs in the genus viburnum. A. OSBORN.

RARE PLANTS

BY W. J. BEAN.

A NEW WILLOW: SALIX MATSUDANA.

THIS willow, although extensively grown in north China, Korea and other north Asiatic regions, has only lately been introduced to this country. It has been confused with Salix babylonica by the French botanist Franchet and others, but is quite distinct. Sargent saw it in the Amur region and described it as a large and handsome tree. It appears first to have been taken from Korea to the Arnold Arboretum by Mr. J. G. Jack in 1905, and in later years it was sent there from north China by the late W. Purdom. According to Wilson, it is very generally cultivated in north China, and he says that it is planted everywhere between Tientsin and Peking. Two specimens, both female, are growing well at Kew and promise to make graceful trees. Although closely allied in a botanical sense to the well known Salix babylonica, it has nothing of the excessively "weeping" habit of that tree; it is, in fact, for a willow, comparatively erect in growth. The young shoots are at first yellowish, changing later to brownish grey. The narrow, slender-pointed leaves are two inches to four inches long, one-third to three-fifths of an inch wide, bright green above, glaucous beneath and quite smooth.

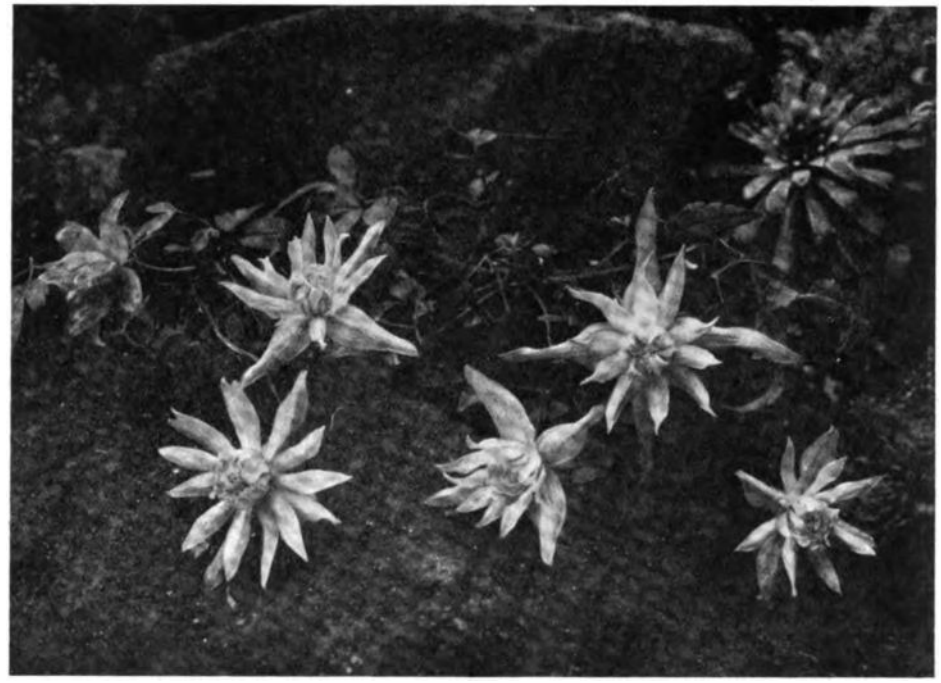
While there is an extraordinary number and variety of willows in existence, the vast majority of them are shrubs and comparatively few are sufficiently attractive to deserve cultivation in gardens. Of genuine trees the number available for cultivation is not great—not so great, at any rate, that room may not be found for this handsome species. It may also prove useful in places where the usual moisture-loving type of willow will not succeed, for, according to the "Plantæ Wilsonæ," it grows excellently on the dry lands in northern China and needs no water supply beyond a scanty summer rainfall.

TILIA INTONSA.

Wilson discovered this interesting lime tree in western Szechuan in the summer of 1903 and sent home seeds to the Coombe Wood Nursery the same autumn. Messrs. Veitch offered it in their catalogue of "New Hardy Plants from Western China" in 1913 under the name of Tilia tonsura, but the name given above was adopted by Mr. Wilson in the "Plantæ Wilsonæ," where it was first authoritatively described. It is a very good name, meaning unshorn, for this lime, which is well distinguished from all other Chinese species of Tilia by its hairy young shoots. I do not think very many trees were raised, but the tree may exist in some gardens under Messrs. Veitch's name or under Wilson's seed number 1569. It does not appear to be a very large tree even in its native forests, and Wilson gives its maximum height as about 65ft. For some purposes, such as for planting in streets, this would prove an advantage. The leaves are of the typical lime tree character, being heart-shaped with the basal lobes more or less oblique and unequal; they are 2ins. to 4½ins. long, scarcely as wide, dark green above, conspicuously ribbed beneath, and have abundant hairs on the ribs and veins. The fruit is egg-shaped, ⅓in. long, distinctly five-angled, and covered with a close white felt. The most distinctive character of the tree, however, is the hairiness of the shoots. It is growing well and makes a handsome small tree at Kew. As Wilson found it at altitudes of 10,000ft. and upwards, it ought to be perfectly hardy, and this it, indeed, appears to be.

WISTARIA VENUSTA.

This wistaria was first introduced to England in May, 1912, when it was shown in flower in the Japanese section of the International Exhibition at Chelsea. It there bore the name of "W. brachybotrys," which is really a synonym of W. floribunda, the wild type of the wistaria we know so well as multijuga. In 1916 Messrs. Rehder and Wilson, in their account of the Asiatic wistarias ("Plantæ Wilsonæ," Vol. II, page 514) described it as a new species and gave it the above name. These authors believe it to be a native of north-east China, southern Manchuria and possibly Korea, and that it is only cultivated in Japan, where it is to be seen occasionally in temple grounds. Like the other wistarias, it is a deciduous climber and grows 30ft. high, its leaves 8ins. to 14ins. long, composed usually of eleven leaflets, but sometimes nine or thirteen. It is related to the common W. sinensis of our gardens, but is well distinguished by the persistent down on the leaves, the short broad racemes, the larger more outstanding flowers, and by the awl-shaped lower lobes of the calyx. The flowers are like those of the other species in shape, 1in. to 1¼ins. long, the standard petal 1in. wide; they are produced in pendulous racemes 4ins. to 6ins. long. On the cultivated plants we have seen, the blossoms are white and often more or less "double," but Messrs. Rehder and Wilson are of opinion that the wild type will prove to have coloured, probably violet-coloured, ones. Any addition to such a glorious group of flowering climbers as the wistarias is sure to be welcomed and, although this is



CLEMATIS MACROPETALA, DISTINGUISHED BY ITS PETALOID SEGMENTS OR SILKY STAMENS.

Digitized by Google

rare in this country at present, we may hope in time to see it frequently in gardens. Like W. sinensis and W. multijuga, it can be kept to a shrubby state by shortening the long shoots once or twice in summer and pruning them to within a few inches of the base in winter. The plants originally shown at the great Chelsea Show had been treated in this way. It blossoms in June.

CLEMATIS MACROPETALA.

There is a section of clematis which in earlier days was considered distinct enough to rank as a separate genus and was known as atragene. In the common type of clematis the showy part of the flower consists of the sepals; petals are absent. But in these atragenes the flower has, between the calyx and stamens, one or more rows of petal-like organs much smaller than the sepals, which may be regarded either as petals or abortive stamens, such as are found in ordinary "double" flowers. Until comparatively recently this atragene group was only known in gardens by two species: C. alpina, an Old World plant not uncommon in cultivation, and C. verticillaris, native of the eastern United States, very rarely seen. Under his number 315, Mr. Reginald Farrer introduced a third species from Kansu which has flowered in several gardens in recent years and has on more than one occasion been shown at Vincent Square. This is C. macropetala, and although it is so new to cultivation, it has been known to botanists for nearly one hundred years. Like C. alpina, it seems to have a wide distribution in nature, and Ledebour, the Russian botanist, described and named it as long ago as 1829 from a plant collected in Siberia.

C. macropetala is a deciduous climber with slender ribbed stems, downy when young, especially near the swollen joints. The leaves are mostly doubly ternate—that is, they are composed of three main divisions, each division having three leaflets, or nine in all. The whole leaf is 3ins. to 6ins. long, the individual leaflet ½in. to 1½ins. long, ovate to lance-shaped, pointed, coarsely and irregularly toothed and nearly or quite smooth. The flowers are solitary, 2ins. to 3ins. wide, borne on a slender stalk about 3ins. long. The sepals, up to twelve in number, are spreading and of a pretty pale lilac colour, each over 1in. long, ½in. to ¾in. wide, usually pointed but sometimes notched at the end. The petal-like segments, also numerous, are more erect, white or nearly so and half to three-fourths as long as the sepals. The centre of the flower is filled with a cluster of silky stamens with yellow anthers. This charming plant has flowered at Kew, with Mr. Vicary Gibbs at Aldenham and with Mr. Woodward at Arley Castle, near Bewdley.

BASKET PLANTS FOR GREENHOUSE AND CONSERVATORY

WHERE continuous changes of pot-grown plants are the rule, as in the case of the conservatory or greenhouse roof climbers have to be used with great restraint, otherwise the plants on the staging suffer from lack of light.

This means that a large area of roof must remain unclad and flowerless, unless baskets are largely employed. From the point of view of the plants beneath them, baskets are innocuous; they obstruct but a moderate quantity of light, while the shadow that they cast is not a permanent one but constantly moving as the sun changes its position, so that it never remains upon any one plant long enough to cause injury. By hanging our baskets over the path, this question of shade is still further reduced and, by watering early in the morning, before visitors are about, all unpleasant drip, etc., is eliminated.

All this is, of course, the practical side of the matter, but let us now turn our attention for a moment to the decorative side of the subject. No one, surely, would argue that (on the score of beauty), a house does not gain enormously by the addition of a series of baskets, pendent from the rafters, spilling a gorgeous shower of beautiful flowers and foliage, and serving to raise the eye from one level of beauty to yet another, instead of to mere white paint and shining glass. That is a question upon which it is scarcely possible for two opinions to exist and, having decided that baskets we must have, let us examine a little more closely into the best baskets, the best plants for these and the method of managing them.

First comes the question of the baskets, and we may say at once that the main matter is size. This must, within limits, be suited to the size of the house in which they are to be hung, but in every case let them be as large as possible. Here are some of the reasons for this recommendation. A large basket provides a greater supply of food and therefore enables a more vigorous growth to be made. It has a better appearance, gives a larger mass of flowers and foliage, and, finally, owing to the larger body of earth that it contains, does not dry so rapidly and therefore ensures better plants and at the same time reduces labour.

Following this, naturally, is the question of the most suitable soil. This, of course, varies to some extent with the kind of plant. For example, one cannot grow a rat's tail cactus in the same soil that one would use for a davallia. However, for the general run of plants, I strongly commend the use of an absorbent soil that retains moisture for as long a period as possible. Experience has proved that a compost of two parts of fibrous loam to one part of peat, with a dash of bonfire refuse (especially if this contains some lumps of charcoal), cannot be improved upon and will grow a wide range of plants perfectly. Do not break the peat up too finely, but let it be in medium-sized lumps, upon which the roots will seize greedily, and let the whole be thoroughly mixed together.

The lining of the baskets with moss is an important point and I cannot too strongly urge the necessity for this lining being sufficiently thick. Place a good layer over the bottom, then line round the sides to a height of about 6ins., and fill to that depth with soil. Make this quite firm and be sure that enough moss has been used to make a satisfactory job, remembering that watering is the test which will show if your moss lining is thick enough to prevent the soil from washing through the wire framework. Proceed thus until the basket is filled to the top, and everything is then ready for the reception of the plants. In the case of plants that demand a good deal of moisture, it is a good plan to finish off the surface somewhat saucer-shaped as this leads the water to the centre and makes its application an easier matter.

Having prepared the baskets, the next point that should be considered is their suspension. In the case of small baskets, a mere hook is sufficient, but, where the baskets are large ones, other measures must be taken or the weight will be found too great to deal with single-handed. A large basket should always be hung from one of the main rafters that is stout enough to support its weight. A thin sash bar is totally unsuitable, and to hang a heavy basket upon one of these is courting disaster.

Raising and lowering such baskets, for purposes of watering and cultivation, is not difficult to arrange and the most satisfactory mode is by means of a couple of stout wires. These should be firmly attached to the chains on the basket and then passed through a stout eye screwed into the roof. From this, the wires should be passed through a series of further eyes until the other end of the wire is brought down to some convenient and easily reached point at the back of the staging, where a turn or two can be taken round a buckle, which will make everything absolutely secure. Sufficient extra length of wire should be left to allow for lowering and care should be taken, for the safety of those who have to pass beneath them, to see that an absolutely secure method of fastening is adopted, which prevents any possibility of slipping. The most satisfactory, as well as the most expeditious mode of watering is to place a large pail or bath upon the floor of the house, fill this with water and then lower the whole basket bodily into it, until the water is just level with the surface of the soil. Allow it to remain here until the whole ball of earth is completely saturated, raise a foot or two and allow to drain, then pull up to the roof again.

One great advantage about this method of suspension is that it enables trailing plants to be kept well clear of one's

Digitized by Google

head as one walks through the house. At first, the baskets may be left low down, then, as growth elongates, they may be raised a little, and so on, according to their progress.

Turning from these details to suitable material, we are faced by such a vast array of delightful plants that selection becomes a by no means easy task. Happily, we are just at the best possible season for making up such baskets as we have in mind, and practically anything can be started with the assurance of complete success. Annuals, perennials, bulbous-rooted plants, ferns, orchids, cacti—one and all of these provide material upon which we may draw and which will provide a feast of beauty, either for many weeks to come (if the choice falls upon a " temporary " flower), or for years, if something more permanent is chosen.

Of summer annuals it is difficult to beat the petunia for sheer gorgeous colour display, although it should be pointed out that it is unsuited for a small basket. More adaptable, in that it is only a question of the number of plants required, the trailing lobelias give us showers of blue (or white, if preferred), that are simply miracles of flowerfulness and continue for weeks. Though more commonly employed as dwarf climbers, the thunbergias are splendid for both large and small baskets and, where unable to climb, are content to droop very gracefully and flower splendidly. Another very striking annual of which splendid baskets can be composed is Mesembryanthemum tricolor, with its vivid display of brilliant pink flowers. All that is necessary with this is to dibble in small seedlings all over the surface (including the sides), and to hang the basket in the sunniest spot available. Only very moderate supplies of water are required and the plants will flower for weeks.

Among more permanent plants, ivy-leaved pelargoniums take a high place and, provided the most floriferous kinds are chosen and they are not over-watered, they seldom fail to render an excellent account of themselves. In cases where these do fail, it is always due to one cause, too heavy shading of the roof glass. Running these very close in popularity comes Campanula isophylla, in both white and blue, one of the grandest basket plants for late summer flowering. Almost hardy, Nepeta Glechoma variegata is ideal for a house that is only heated to exclude frost and will provide elegant baskets of foliage that are decorative for a very long period.

A DECORATIVE BASKET OF AN IVY-LEAVED PELARGONIUM.

Akin to this in hardiness is the old-fashioned Saxifraga sarmentosa or " mother of thousands," a plant that is not very much appreciated at the present day. Given rich soil and plenty of water, the beautifully variegated leaves of this plant attain an immense size ; while the trailing stems bearing the " baby " plants reach a great length. We have not finished with the plant yet, however, for it is in spring or early summer when the tall arching flower spikes expand their blooms that the plant attains the summit of its glory and a good basket, with half a dozen or so of these superb stems in full perfection, forms a sight that is not readily forgotten. If your house is a warm one, you may grow its sister plant—Saxifraga sarmentosa tricolor—before which it must be admitted our humbler plant pales into significance. In this case the foliage is astonishingly brilliant, each leaf of vivid green zoned with white and margined with rich crimson red.

Turning from old to new, do not pass by Coleus rehneltianus. This again combines flower and foliage and is easy to raise from seed sown in early spring, or even now when the baskets are needed as a succession to an earlier flowering plant. The growth is close and creeping, the colour of the leafage a rich reddish-brown, with spikes of blue flowers.

In a really cool house that can be well shaded when the sun is bright and where the atmosphere is always moist, the graceful fuchsia is beyond all praise. Everyone who is familiar with these plants will be aware that they differ tremendously in their habit, and it is those that have long pendent branches that droop naturally which form the most suitable material for basket culture. Such baskets are very quickly formed by inserting recently rooted cuttings and allowing these to grow straight ahead, without any stopping. A really rich soil should be provided, for no plant demands a richer rooting medium than the fuchsia if the maximum luxuriance and vigour are to be obtained.

Begonias of the Lloydi, Bilkey and Starfish types, are simply ideal and never are their brilliant flowers displayed to greater advantage than when viewed from beneath. It is not yet too late to plant started tubers and these, with reasonable care, will literally bloom for months.

A curious plant, this time a fern, that never fails to attract, is the Stag's Horn, Platycerium alcicorne. This hardly needs a basket in the ordinary sense of the word, in that it is sufficient to form a ball of peat and bind this together with some copper wire. The young plants are then planted into this and, in the course of a couple of seasons, will cover the ball with a wrapping of their curious flat sterile fronds. From the growing point in the centre of these, the " horns " arise annually. These horns are broad, flat, deep green ribbon-like structures, which fork at the ends like the antlers of a stag, hence the name.

In the temperature of a warm house, one has a splendid range of most interesting plants in the davallias, another genus of ferns. These luxuriate on balls of peat, in the manner described above, and rapidly cover the surface with their queer creeping rhizomes, from which the names of Hare's Foot, Squirrel's Foot, etc., have been derived. From these rhizomes spring most elegant finely divided fronds, that are notable for their long enduring qualities. One little hint may be useful in connection with these, and that is, do not over-water. This does not mean that the plants should be allowed to become dry, but they should be allowed to approach this condition before further supplies are given. Among other ferns, the nephrolepis are conspicuously successful and beautiful and their graceful habit and arching fronds are never displayed to better advantage than when grown in this way.

Adiantums, too, are remarkably striking and very easy to grow ; the fragile fronds standing exposure to the light well, if they have not been too heavily shaded earlier in their lives. A point that should not be overlooked in the case of all these more tender-leaved plants, is to suspend them where they will not be too near to the open ventilators, for draught is an enemy which will do a great deal of irreparable injury in a short time.

One might go on mentioning plant after plant, almost indefinitely, but let one more suffice. Though it is at the bottom of our list, that is by no means the position it occupies in popular esteem ; I allude to Asparagus Sprengeri. This is one of those always useful evergreens, that is ever with us throughout the year. It needs a really large basket and plenty of water and will then throw its trails to a length of several feet, forming a splendid picture.

H. W. CANNING-WRIGHT.

SOME EASY-GROWING ROCK PLANTS from SEED

BELOW is a selection of rock plants, all of which are good and of easy culture and can be grown very satisfactorily from seed with little trouble, and, as a great many people are particularly interested in raising their own plants to furnish gaps that crop up in the rock garden, the small selection that follows might be helpful. A compost that would be efficient (for the majority of easy-growing plants) for seed sowing would be, say, loam, leaf-mould and sand in equal parts. This should be well mixed and put into well drained pans or boxes and then thoroughly watered before the actual seed sowing takes place. By the way, if it is convenient to sterilise the compost before use, it is certainly advisable, as it will kill any vermin in the soil and destroy weed seeds that may be present, and so do away with the delicate job of weeding tiny seedlings. After sowing, the pans should be placed under glass and kept in darkness until germination takes place. In all cases sow thinly, covering the seed with about its own depth of soil generally. Frosts are extremely helpful to the germination of seeds, so that the beginning of the year is really a good time to sow.

LINARIA ALPINA.—This is a dainty little toad-flax which grows freely and blooms continuously throughout the summer, enjoying almost any sunny position in a well drained gritty mixture. It bears flowers of rich violet with a conspicuous throat of deep orange on 3in. spikes. The foliage is grey and fleshy. There is also the pale pink variety rosea, which is quite as charming; in fact, the two plants grown together are most attractive. It comes very readily from seed, and also produces seed in abundance.

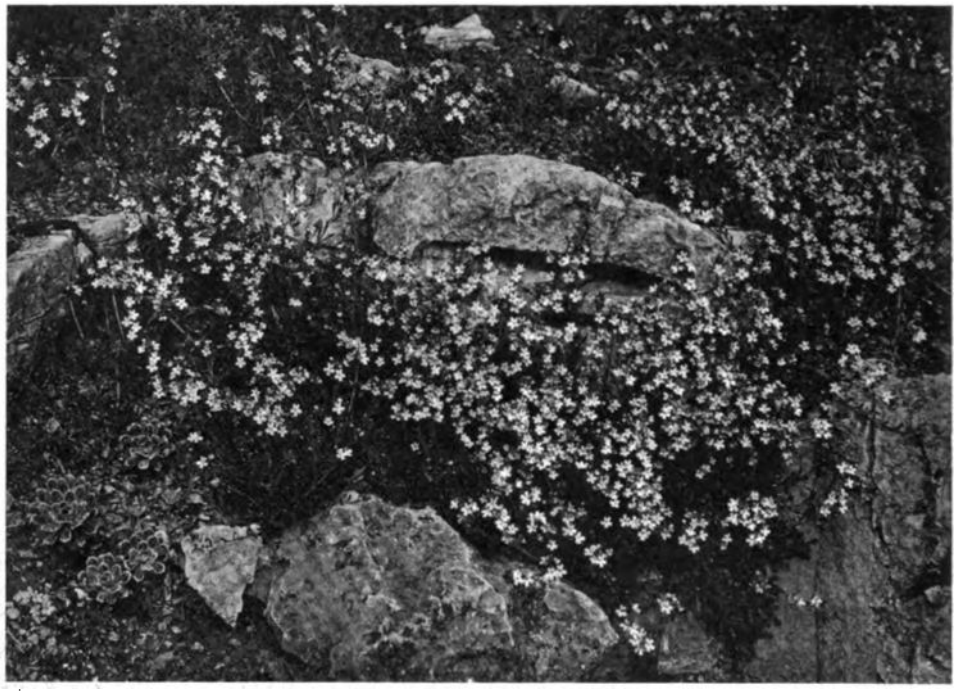
CYNOGLOSSUM AMABILE is at the most only biennial, often annual, but nevertheless it is an excellent plant, hailing from China. The leaves are long and narrow and of a greyish colour. The flowers are borne on stately branched stems from 1ft. to 2ft. high, and may be likened to large forget-me-nots of a dazzling azure blue. It also makes an excellent plant for the front of a border. There is a white variety, alba, which, of course, does not compare with the splendour of the blue; still, odd plants dotted about in a mass of blue do not look amiss. Any ordinary good soil is suitable combined with a sunny aspect and good drainage.

PAPAVER ALPINUM will do perfectly well with similar treatment to Linaria alpina, and but little attention is needed after it leaves the seed pan. The tiny seedlings are very brittle and should be handled with care. Flowers of various shades of orange, yellow and white are produced in quantity in the shape of dainty little poppies borne on slender 3in. or 4in. stems. The seed is extremely small, and when sown should only require a thin covering of sand over them.

IBERIS GIBRALTARICA.—In a batch of seedlings of this perennial candytuft there usually are a great many forms in all the varying shades of lilac and mauve. Some are, often, particularly good, but all are worth having. In the event of possessing a choice form, it can be increased by cuttings to keep it true; seed of it, no doubt, would give variation again. The large, flat, round heads of flowers are attractive, and often the main body of the plant is completely hidden. It flowers about May or June, and is 6ins. to 9ins. high. Sunshine and ordinary soil suit admirably. The plant has woody stems and dark, glossy green leaves of a fleshy type.

ARENARIA MONTANA.—This is probably one of the most popular of the sandworts, and is a good doer, enjoying a well drained and sunny position. It grows rapidly where it is suited and, from somewhat trailing shoots, it produces abundant large white blossoms continuously. It is a good perennial and seeds freely. For growing on a wall it is one of the best.

SISYRINCHIUM ANGUSTIFOLIUM.—This is a plant of extremely easy culture, requiring nothing more nor less than a very sunny position in a well drained compost. It is commonly known as blue-eyed grass, having grass-like leaves about 6ins. long, from the midst of which appear numerous bright blue flowers in May or June, keeping up a succession over a long period. There is also S. chilense, the same in every detail except that the flowers, which are white, are beautifully pencilled with delicate mauve lines. S. convolutum is dwarfer in habit, with wider, iris-like foliage and bright yellow flowers nearly 1in. across. The seeds, which are like pellets, germinate very readily.



ERINUS ALPINUS FLOURISHES IN ANY SUNNY NOOK OR CRANNY.

ONE OF THE MOST POPULAR AND PICTURESQUE OF SANDWORTS, ARENARIA MONTANA.

ERINUS ALPINUS is another plant of easy culture, and will thrive and flourish in almost any sunny nook or cranny in very ordinary soil. Often it will seed itself and grow to perfection where soil is very scarce; for

Digitized by Google

instance, in tiny crevices in the rocks where seed just happened to lodge. It flowers throughout the summer, bearing 3in. spikes of rosy purple. There is also a good white variety, E. alpinus albus.

LYCHNIS LAGASCÆ is a neat little plant of rather a trailing habit. Throughout the season it continues to produce its dainty pink, white-eyed flowers on stems about 3ins. high. Its leaves are small and of greyish green colour. In a sunny position in a gritty mixture it thrives well.

ANEMONE PULSATILLA.—The pasque flower is one of our prettiest British natives, a flower that arrives with the early days of spring. From the day its silky buds are visible to the ripening of its seed it is handsome. The buds, clothed in a mantle of dense silvery silky hairs, are very attractive, and, no doubt, are more so when they burst and present their large violet-purple blossoms. The flower-stalks are usually from 6ins. to 1ft. high in cultivation, though in their wild state they are but 2ins. or 3ins. high. The seeds are borne in large fluffy heads. A hot, dry position seems to be most desirable, in a very chalky compost. Plants are most satisfactorily moved when in growth.

HYPERICUM KOTSCHYANUM.—This small, prostrate St. John's wort is not too commonly grown, but is always worthy of a position on the rock garden. It comes true and readily from seed, and asks only for a hot, sunny position in a well drained gritty soil. It forms a mat of grey foliage and bears pale yellow flowers 1in. in diameter. H. reptans also makes a tight mat on the ground of bright green leaves on reddish stems and produces abundant golden yellow flowers in late summer.

DIANTHUS DELTOIDES SUPERBUS is a fine form of the maiden pink, having sumptuous crimson flowers and foliage of a dark reddish brown colour. Its habit lends itself to a position where it can hang over a rock from a pocket of ordinary good soil with a sunny aspect. The white variety albus makes a fine contrast when the two varieties are planted together. Both are easily grown from seed. As candidates for a wall garden they rank among the best.

CALAMINTHA ALPINA is a good and easily grown plant flourishing in very ordinary circumstances. The plant is aromatic, and in habit, mat-like. The spikes of blossoms are borne profusely, 4ins. high, the flowers being of an intense violet shade.

VIOLA GRACILIS.—A crop of seedlings from this lovely violet Grecian species may prove very interesting, although a very small percentage may come true, there is always the possibility of raising choice hybrids, which can be selected and increased later by cuttings or division.

F. BARKER.

LYCHNIS LAGASCÆ WITH ITS DAINTY PINK FLOWERS; ONE OF THE JOYS OF THE ROCK GARDEN.

THE STRAWBERRY BED

BY E. A. BUNYARD.

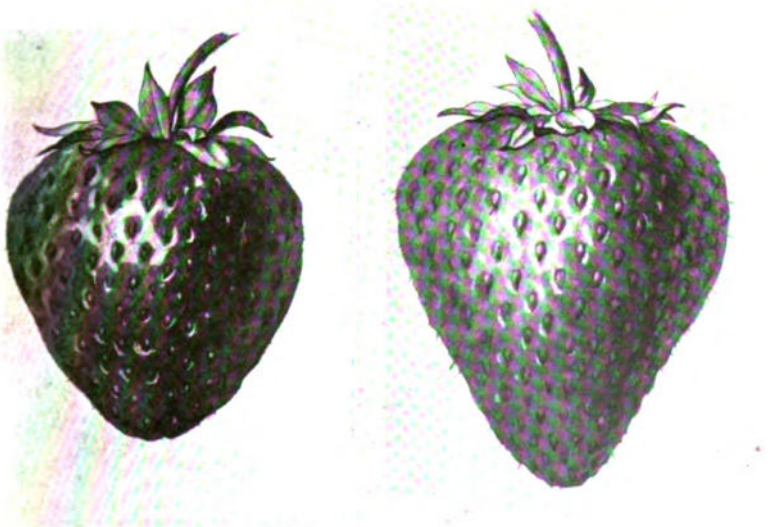
THE strawberry beds under a bright March sun with winds veering from north to north-east, do not invite a lingering visit. A few leaves lay discoloured upon the steely soil and give no promise of June's fruitfulness. But to everything its times and seasons, and we know that a few months hence we shall be turning thitherwards to see the first reddening berry, drawing aside the shading leaf and saying—"perhaps to-morrow!" And now comes in the thought that in this lies the whole art of strawberry eating. How wise were our primitive forefathers ("pagan," I regret to say) who imposed a strict taboo on fruits until the appointed time of their ripeness. Until the ceremony of First Fruits had been celebrated, penalties dire and unmentionable awaited the premature taster. This custom still lingers in vintage countries and there is a distant alpine valley where choice apples have a close season in which they may not be gathered or sold.

It is, I fear, useless at this time to look either to church or state for measures of such profound wisdom, and it thus falls to the individual to emphasise once again that the bulk of the strawberries eaten in this country are only half ripe, and half ripe strawberries, be they never so well tempered with cream and sugar, bring acidity to the queasy stomach and to the rheumatic an added twinge.

But even such valetudinarian ramblings suggest that there are degrees of flavour and sweetness, and a wise selection may go far to eliminate the less desirable. To open the season, almost *hors d'œuvre* by its earliness, I should plant Black Prince, a small fruit, but solid and well flavoured. The kitchen will welcome this for jam and bottling as it keeps a rich red when cooked, unlike the mousy blue that many varieties assume in bottles or jars.

To follow it is impossible to overlook Royal Sovereign, which has retained its sovereignty for many years and is of excellent flavour when really "finished." Sir Joseph Paxton when properly ripe assumes a rich claret tinge and is then excellent for a general utility variety. The vigour of these two sorts makes them remarkable in nearly all soils.

The Duke, a new comer, is worthy of a trial among the earlies, but I am not yet quite convinced of its flavour. It seems, however, to have all the other virtues.



ON THE LEFT, SIR JOSEPH PAXTON; ON THE RIGHT, ROYAL SOVEREIGN.

Digitized by Google

For mid-season there are two claimants and the best solution of the puzzling problem as to which to choose is, I think, to have both. They are British Queen and Dr. Hogg. While lacking the fatal facility which would endear them to market growers, they are unequalled in flavour and well worthy of the extra attention they demand. Abundant water and manure must be given on the lighter soils.

For the later sorts Givon's Prolific, Countess and Waterloo are worth consideration. The first is a large fruit, but of excellent flavour, the Countess smaller and more solid. Waterloo is large and of a very dull brownish crimson, indeed, it does not do to think of undercooked kidneys when eating this fruit. Granted such oblivion much delight will be found in its ruddy succulence.

This would form a standard list about which there would be an agreement as general as can be hoped for in matters of taste. Most of them are classics and the newcomers at least follow the classic tradition. For those who journey hopefully outside these limits there are still a few sorts worthy of consideration. Aprikose, a variety with a curious flavour, more Hautbois than Apricot in my opinion; the old Hautbois itself, or its "amelioration," Royal Hautbois; the so-called pine flavour of Louis Gauthier, are all beacons to the adventurous.

In cultural matters the outstanding fact is that the strawberry is a shallow-rooted plant and quickly fades in summer droughts. All soil operations must therefore aim at collecting and preserving water. An abundance of humus or vegetable matter, straw manure, leaf mould, spent hops and the like are potent aids. A good surface mulch of straw helps to conserve the moisture already held in the soil. Hay for this purpose is anathema, in a wet season it rapidly goes mouldy.

Strawberries much appreciate a change of air and soil, and just as the Scotch potatoes (and Scotchmen) develop unexpected virtues in the more genial south, so do strawberries greatly benefit by a change of locale. Unlike their Scotch compatriots the change seems to work well in either direction.

No garden should be considered complete without a few rows of alpine strawberries, and how few English gardens contain them. We go to Switzerland and eulogise their fragrant charms, forgetting each year to sow the necessary seed that we may have them fresh at our doors. If sown in autumn in a box in a cold frame they can be pricked out in April and give a crop the following autumn. Again, if sown now a late crop will result which will be very welcome in September and October. The plants will fruit again the following summer. It is best to raise a fresh batch of seed each autumn, as, after two crops have been taken from the plants, they usually lose vigour. There is a solidity about the flesh of alpines which renders them unsuitable for jam, but the right way to eat them is known to the epicure, and a sweet white wine (no sugar) forms its principal ingredient.

Many who are forbidden the common or garden strawberry will find that alpines may be enjoyed without fear or regrets.

The larger garden forms of alpines, such as Millet and Belle de Meaux, are very good, but not quite, I think, so fragrant as the wild types.

A BRILLIANT DISPLAY AT VINCENT SQUARE

THE Show at the Royal Horticultural Society's Hall at Vincent Square on March 25th and 26th was very fine, although, unfortunately, the attendance on the first day was not so large as usual, owing to the bad weather.

In anticipation of the special show of the British Carnation Society on March 27th, a report of which will be found in the next issue, carnations were quite an important feature in the hall. Mr. C. Engelmann had an immense collection, which received a gold medal. Messrs. Allwood Brothers also set up a group. Messrs. Stuart Low and Co. and Messrs. Keith Luxford and Co. also showed fine collections. These are noted elsewhere.

Daffodils are late this year, and there were only two collections of narcissi. Messrs. Barr and Sons staged a large collection, in which seedlings, with their intriguing index letters and numbers, attracted attention. These were mostly promising large trumpet varieties, a type which predominated. Of the named large trumpets Golden Song stood out prominently by reason of its large size, perfect form and rich yellow colouring. Duke of Bedford, St. Hilda, Van Waveren's Giant, Danesfield and Yorrick are the names of other admirable examples of this showy type. Besides these giants of the trumpet daffodil world there were many smaller ones of

ANEMONE PULSATILLA MADAM VAN DER ELST.

A SPLENDID SPIKE OF CLIVIA MINIATA.

Digitized by Google

very graceful habit and often with twisted perianth segments. The Leedsii, Barrii and incomparabilis varieties were also well represented.

Towards the other end of the hall Messrs. J. R. Pearson and Sons displayed a good collection of blooms "from home-grown bulbs." These were fairly representative of the different types, and all were of good quality. Among the Poeticus varieties we noted John Masefield; while among the Leedsii varieties was a delightful vase of the Hon. Mrs. J. L. Francklin.

Alpines, shown both in small pots and set out in miniature rock gardens, were numerous. Mr. M. Prichard had several plants of his new variety of saxifrage, with SS. Riverslea, Wetterhorn and many others. Messrs. Skelton and Kirby, and Messrs. Carter, Page and Co., also had interesting examples, such as Latina and S. oppositifolia splendens. Androsace Sundermanni, with Anemone vernalis, Saxifraga kewensis and S. Sartori were shown by Messrs. R. Tucker and Sons.

Hardy primulas and polyanthuses provided rich masses of colour. The forms and varieties of Primula Juliæ seem to be legion and to be increasing apace; but all are well worth growing, as they make compact plants which flower with uncommon freedom. Messrs. W. H. Rogers and Son had a good type in large quantity. Messrs. Waterer, Son and Crisp showed irises, polyanthuses and other spring plants. A good variety of Primula rosea was shown by Messrs. Maxwell and Beale. Mr. G. W. Miller had a large collection of polyanthuses associated with the lyre flower (dielytra), together with Orobus albus roseus. A charming patch of double lilac primroses was shown with Daphne Mezereum and Japanese maples by Mr. F. G. Wood. Messrs. R. Gill and Son had what appeared to be a single plant of the common primrose bearing 1,400 flowers, and this excited more admiration than their really excellent exhibit of anemones.

Bulbous spring flowers were well represented by the shallow baskets of admirable hyacinths staged by Messrs. Carter and Co.; a large collection of Darwin tulips in bowls of fibre, by Messrs. R. H. Bath, Limited; and Dutch tulips of glowing colours, by Messrs. R. and G. Cuthbert; while the Maytham Gardens contributed vases of cut bloom of Darwin varieties.

Pieris (Andromeda) floribunda, associated with Incarvillea brevipes, shown by Messrs. Bakers, Limited; a rock garden, by Messrs. Pulham Brothers; flowers of various hellebores, by Mr. G. H. Beckhusen, were all of interest.

Shrubs were well shown by various exhibitors. Messrs. L. R. Russell, Limited, had a large group of azaleas, including the charming little Japanese varieties; wistarias and clematis, with the fragrant Boronia megastigma. Mr. G. G. Whitelegg showed masses of Azalea mollis of glowing colours, cytisuses and various irises. Mr. G. Reuthe had rhododendrons, camellias and various alpines. Messrs. W. Cutbush and Sons showed prunuses, azaleas, Daphne Cneorum and such like in association with a well planned little rock garden. Rhododendrons, azaleas and primroses, with some good spikes of hippeastrums, were displayed by Messrs. John Peed and Son.

Besides their large collection of daffodils, Messrs. Barr and Sons had a pretty group of Crown Imperials, forsythias, irises and coloured freesias.

Acacia pendula, A. armata, hippeastrums, clivias and other greenhouse plants were staged by Messrs. Stuart Low Co. Lady Aberconway sent from North Wales some splendid spikes of Clivia miniata. The Misses Allen-Brown made a mound of violets, while Mr. J. J. Kettle set his out in pots and vases.

Among the roses, Mr. George Prince's two large stands of Austrian Copper provided rich colouring; he also had magnificent vases of Richmond, Allan Chandler, the new semi-double of rich rosy crimson colour. The climbing Lady Hillingdon, shown by Mr. E. J. Hicks, with Charles E. Shea, Mrs. George Norwood and Columbia, were excellent. The Rev. J. H. Pemberton also showed roses.

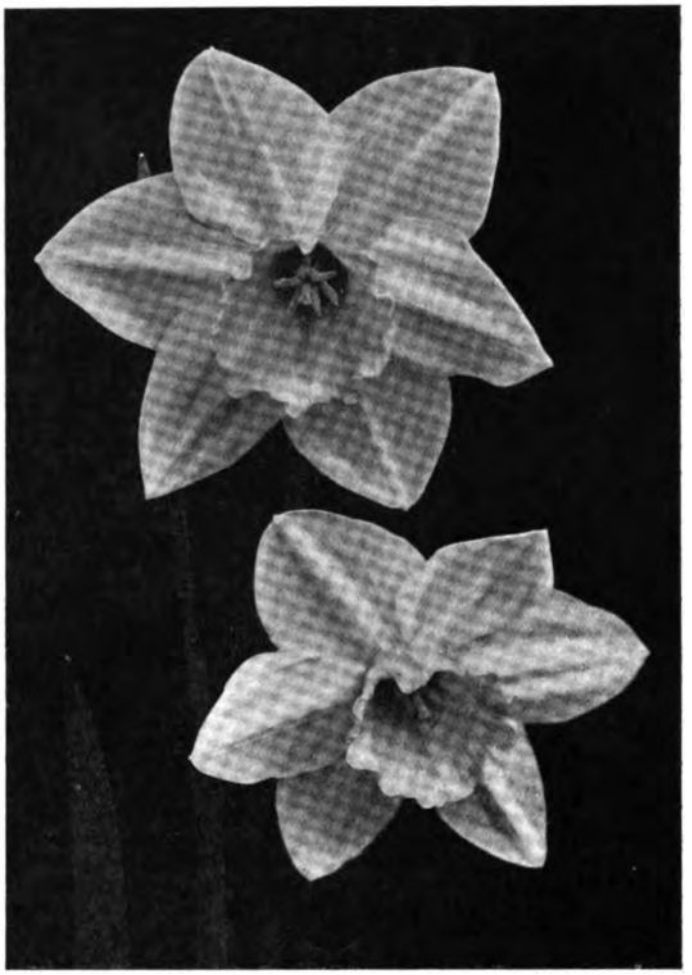
The only collection of vegetables was an admirable one by Messrs. Sutton and Sons. Their broccoli included Superb Early White, Snow White, Satisfaction and Winter Mammoth, all bearing compact milk-white heads. Cucumber Selected Telegraph and French Bean Early Giant were as perfectly shaped as though moulded. Messrs. G. Bunyard and Co. had splendid dishes of such late-keeping apples as Newton Wonder, Wagener, Sir John Thornycroft and Sanspareil.

NEW AND RARE PLANTS.

CROCUS QUEEN OF THE BLUES.—In size of bloom and in freedom of flowering this is a magnificent variety of the Dutch crocus, though the large rounded flowers were so numerous that the pots recalled the old saying that "one could not see the wood for the trees." The colour is mauve, of which the darker tones predominate. Award of merit. Shown by the Director, R.H.S. Gardens, Wisley.

NARCISSUS ADELA.—A splendid incomparabilis daffodil of large size, good form and with plenty of substance in the segments. The perianth is white and the long tube is sulphur yellow colour. Award of merit. Shown by Mr. P. D. Williams.

N. AUGUSTE.—This fine novelty is a Barrii variety with a poeticus perianth.



A NEW NARCISSUS, ELSPETH, SHOWN BY MR. P. D. WILLIAMS.

The corona is canary yellow coloured with a definite band of orange on the frilled edge. Award of merit. Shown by Mr. P. D. Williams.

N. HESLA.—A large, substantial, rich yellow incomparabilis variety of beautifully rounded shape. Award of merit. Shown by Mr. P. D. Williams.

N. KILLIGREW.—A giant Barrii variety of rounded form. The perianth is canary yellow and the frilled corona is a rich orange-yellow. Award of merit. Shown by Mr. P. D. Williams.

IRIS UNGUICULARIS PEACOCK.—A very charming dwarf iris which bears relatively large flowers of most delightful colouring. The falls are generally purple coloured with white rays and a central golden patch towards the base. The short standards have a metallic sheen. Award of merit. Shown by Mr. W. R. Dykes.

SAXIFRAGA LADY BEATRIX STANLEY.—A fascinating little incrustated saxifrage derived from S. lilacina and S. Goldroneana. The cushion-like plant has just a suspicion of silveriness. The short-stemmed flowers are relatively large

Digitized by Google

and of a bright rosy lilac colour. Award of merit. Shown by Mr. M. Prichard.

ORCHIDS

FIRST CLASS CERTIFICATE.

ODONTOGLOSSOM EXIMIUM, McBEAN'S VAR.—A remarkable result in which the immense flowers have the segments unusually developed, and heavily blotched with reddish-purple. From Messrs. J. and A. McBean, Cooksbridge, Sussex.

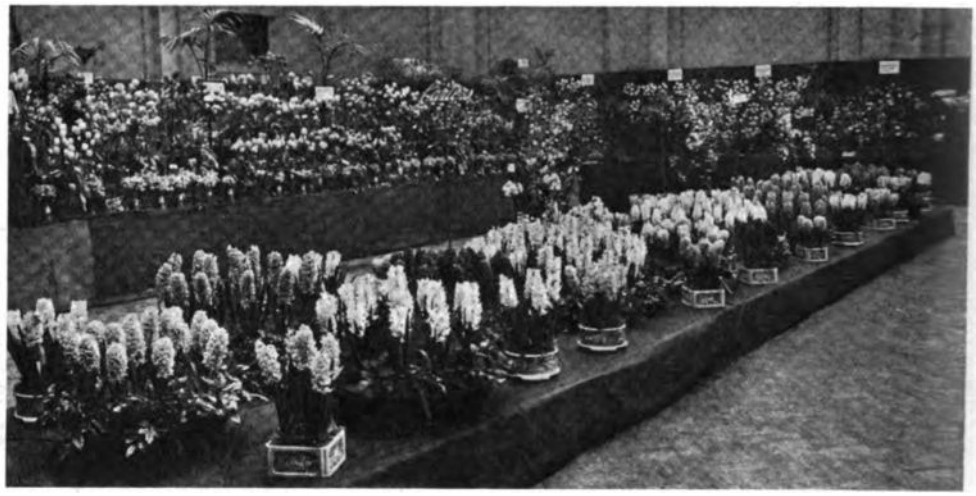
AWARDS OF MERIT.

ODONTOGLOSSUM MODEL (Aglaon × promerens). A pleasing hybrid bearing a spike of eight flowers, of model formation, rose-flushed, and prettily marked with chocolate. From J. J. Bolton, Esq., Claygate, Surrey (gardener Mr. Lyne).

CYMBIDIUM KITTIWAKE, HOLFORD'S VAR. (Gottianum × Dryad).—This plant carried a spike of eleven flowers, pure white, the labellum effectively marked with rose-purple lines and spots, the column rose-coloured. From Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Glos. (gardener Mr. H. G. Alexander).

CYMBIDIUM ALEXANDERI VAR. EDUSA.—A beautiful hybrid, the large flowers blush tinted and having the labellum marked with reddish spots and suffusion. From the Hon. Henry D. McLaren, Bodnant, N. Wales (gardener Mr. F. C. Puddle).

BRASSO-CATTLEYA THE GLOBE (B.-C. Cliftonii magnifica × C. Trianæ "The Baron").—A most promising hybrid perpetuating the well known qualities of the former parent, but improved in shape, all the segments being roundly formed and well coloured. From Messrs. Armstrong and Brown, Tunbridge Wells.



MESSRS. CARTER'S EXHIBIT OF HYACINTHS.

BOTANICAL CERTIFICATE.

OPHRYS ATRATA.—A terrestrial species collected in Syracuse by the exhibitor, Major Albert Pam, Wormley, Bury, Broxbourne (gardener Mr. S. Streeter). Several plants were shown growing in a shallow pan, and bearing a total of eleven erect spikes of spider-like flowers.

NOTES ON VEGETABLES

WORK TO BE DONE IN THE VEGETABLE GARDEN DURING THE LAST HALF OF APRIL.

IF asked to name the period of the year that I considered to be the most worrying in the vegetable garden for both amateur and professional gardener, I should, probably, without hesitation refer to the last fortnight of April. So much clamours for attention that it is a problem to decide which operation to take in hand at once, and which to defer to another time. The man who has commenced work in good time, and during March and the early part of April has been busy putting in certain seeds and plants, and who now desires to continue his efforts along proper lines, finds his hands more than full, for the jobs to be done are now clashing with the attention the earlier work demands; while as for the man who has procrastinated, or who has been held up by adverse weather conditions—well, his lot for the moment is anything but a happy one in his efforts to make up leeway.

If there are any who are right behind and who have not yet finished ground preparation, the best advice for the moment must be to get that ground broken up as soon as it can possibly be done. The beneficial method of trenching will probably have to be abandoned altogether, and the soil should be as deeply worked as it can be by means of the spade.

Those who are well up to time should pay attention to crops that have started, especially the seedlings, and the Dutch hoe should be kept busy around them, to keep the ground in good tilth and the weeds down. Steps should be taken, where necessary, to protect such crops from the ravages of various enemies, especially birds, mice and slugs, which will now be busy. Frost, too, should be guarded against, as sharp little snaps at night or early morning are to be expected, and some form of protective measure adopted to keep tender young seedlings from harm. Early-planted potato "sets" may be coming through well, and the soil should be drawn carefully over them, so that the frost cannot cut the young tender haulm and spoil the crop. Other crops may be protected by means of light litter, bracken, or spruce boughs, placed over or round them. In fact, the gardener will have to be busy from early morning to late at night if he means to make a real success of his efforts.

In the following notes I will deal as briefly and as concisely as possible with each of the various crops in turn.

GLOBE ARTICHOKES.—Where suckers were potted up last autumn for wintering in cold frames, they may now be planted out on well prepared and enriched ground, in rows 5ft. apart, allowing 4ft. between the plants. After planting, a mulching of litter should be applied.

JERUSALEM ARTICHOKES should be well through now, and they merely require attention in the form of hoeing and the removal of side shoots so as to leave only the main stem.

ASPARAGUS.—Where this crop is in great demand as a forced early vegetable it should be sown without further delay, as it is now getting late for such work. Sow thinly in drills 1ft. apart on light warm soil in the open, and thin out to a foot apart when large enough to handle.

FRENCH BEANS.—If these are growing under glass in pots, make a second sowing, and at the end of the month the first sowing on a warm border outside can be made. Two good varieties are Canadian Wonder and Ne Plus Ultra.

GLOBE BEET for main crop should be sown at the end of the month, in drills 10ins. apart; sow rather thickly, and thin out later on. Try Crimson Ball and Selected Globe.

BROCCOLI AND BRUSSELS SPROUTS should now be sown in the open, on fairly well prepared ground, for the main supplies later on, and the seed should be protected by means of netting from birds, which are very partial to them. A warm position should be chosen for the seed bed. Where Brussels sprout plants have been raised in boxes in a cold frame in March, they should now be pricked out in a frame about 4ins. apart. Good varieties are: Broccoli—Self Protecting, Snow White, Leamington, Snow Winter White, Late Queen and Model; Brussels sprouts—Dwarf Gem and Aigburth.

CABBAGE for summer supplies should be sown in the same manner as Brussels sprouts, and a good sort is Rosette Colewort. Hoe through the spring cabbage bed, removing dead leaves and give a dusting of nitrate of soda.

CARROTS for the main crop should be sown without delay, if this has not already been done. Champion Horn, Long Surrey, Model and New Red Intermediate are all reliable sorts.

Digitized by Google

CAULIFLOWERS that were raised from seed in the autumn and wintered in cold frames should now be planted out on well prepared ground if not previously done, allowing 30ins. each way between plants.

CELERY.—February-raised seedlings that were pricked off in March should be well hardened off now. Where there is a mild hot-bed some of the more forward plants should be planted in frames for early supplies, blanching later by means of brown paper. March-raised seedlings should be pricked off.

CHICORY may be sown like carrots, in drills a foot apart and an inch deep, on well prepared ground that is not too rich in character.

ENDIVE should be sown at intervals of ten days, making at least three sowings to maintain supplies, and where the first sowing has not already been made, lose no time in doing this. Green Curled and Batavian should both be used.

LEEKS.—Where exhibition leeks are desired, the trenches for these should now be ready and a planting made from those raised for the work, and others for ordinary use should also be planted out for early supplies. For a later crop make a broadcast sowing on a piece of prepared ground, if not already done, and sprinkle the seedlings frequently if a dry spell comes along. The following are excellent varieties: Musselburgh, International and Improved Lyon.

LETTUCE.—Continue to make small sowings of cos and cabbage sorts, at intervals of ten days or so, to maintain supplies, using such as Mammoth and Superb Cos as cos varieties, and Ideal, Marvel and Golden Queen as cabbage forms. Where plants were wintered in cold frames, they should now be planted out to grow on for use.

MARROWS.—A sowing should be made of such varieties as The Sutton, Pen-y-byd, Moore's Cream and Long Green, for open planting later on; and where seed was put in during March, the resulting seedlings should now be planted in frames on a mild hot-bed.

ONIONS for the main crop should be sown at once, if not already done, using such varieties as Ailsa Craig Selected, James' Long Keeping and Walker's Exhibition. Where seed was sown under glass, the plants thus raised should, after having been well hardened off, now be planted out on thoroughly well prepared ground, in a most careful manner, lifting from the boxes with the aid of a trowel and with as little root disturbance as possible. Allow up to 14ins. each way growing space.

PARSLEY raised in boxes may now be pricked out 6ins. apart, with a foot between rows. Sprinkle each day until established.

PEAS raised under glass, in boxes, and now hardened off, should be planted out on well prepared, deeply worked ground, staking and netting them to protect them. Make a sowing in the open now, and maintain at intervals of about ten days to keep up supplies. Allow plenty of growing room. Gradus, Edwin Beckett, Duke of Albany, Quite Content and Autocrat are good sorts.

POTATOES.—The main crop should be put in now, if this has not previously been done, such varieties as Arran Chief, King Edward and Kerr's Pink being well tried sorts.

SPINACH.—Successional sowings, say at fortnightly intervals, should be maintained of the round-seeded varieties, of which Victoria is a good sort. Spinach requires well enriched and well worked ground, and forms an ideal crop between rows of peas, benefiting by the shade cast by the rows.

TURNIPS.—Make additional sowings in various positions, and thin out those previously sown and now showing, and use the Dutch hoe well around them.

Seed should be sown at once of the various brassica family, such as kales, savoys, etc., required for winter supplies, making small seed beds of each sort, and sowing on fairly firm ground, covering the seed with netting to keep off the birds.

Two cautions are necessary in conclusion. Varieties have been referred to, but these are only named where I have found them really reliable in use; but this fact may not apply to every district, and where other varieties are a marked success in one neighbourhood or another, do not hesitate to employ them, trying out those that have not been previously used, on experimental lines in order to learn their capabilities.

The last word of advice is that, although it is a fine rule to endeavour to sow to date, yet this should be waived if weather conditions affect the soil so as to render it adverse to such work, for it will always be found better to delay even a fortnight, until good conditions prevail, rather than sow on ground which has been rendered unfit. EDWIN BECKETT.

SPRAY FLUIDS AND THEIR USES

THE time for spraying depends really upon the pest or disease to be attacked, but as it is useless now to advocate winter spraying, it will serve no useful purpose to deal with caustic soda or alkali washes, or to urge the fruit grower to cleanse his trees of moss and slimy algæ. It is spraying time now, however, for trees that are infested with apple sucker (Psylla mali), capsid bug (Plesicorus rugicollis), codlin moth (Carpocapsa pomonella), lackey moth (Bombyx neustria) and a lengthy list of other pests that are vulnerable to attack just as bud clusters are separating, and prior to the actual opening of the blossoms.

Of the chemicals that may be used just now, up to the flowering period, and again when the petals have fallen, nicotine, sulphur, lead arsenate, potassium sulphide and, perhaps, salt may be considered among the most important, but, of course, the spray must be chosen for the particular purpose for which it is required.

Spraying mixtures, like quack medicines, are sometimes put on the market with the claims that they will cure nearly all the ills that may befall trees and plants, but the universal spray is no nearer our grasp than the pill that will keep humanity immune from all diseases. The gardener, amateur or professional, should discover the identity of the pests that trouble the trees or bushes and select the spray to meet the case. The information may be obtained by sending specimens of the pests or diseased shoots from the trees or plants to one of the many organisations that are concerned with the advancement of horticulture, and it is better to take a little trouble to get on the right track than to flounder about in the dark. Haphazard spraying is little better than useless, and it is too laborious and too expensive to be carried on ineffectually. All the substances mentioned above are serviceable and capable of good work, but in some cases individually, and in others in combination, they should be used for specific purposes, not with the idea that either one or the other will do.

Nicotine is of great value, a deadly poison, and powerfully effective against many chewing and some sucking insects. Caterpillars, aphis, capsid bug, weevils and many others cannot exist on foliage that is coated with nicotine, nor when their hides are saturated with it. Soft soap is a very useful "spreader" for nicotine, ensuring that the surface of foliage shall be equally and evenly covered, but it is not so helpful where the aim is to kill by contact, *i.e.*, by soaking the bodies of the insects.

Aphides and some caterpillars exude a sticky, slimy fluid through their skins, or in some cases spin a filmy protecting web over their retreat, and soapy fluid merely runs off like water from grease. By using nicotine in combination with sulphur (dry soluble) or sulphide of potassium the protective covering of the insects is penetrated, and thus the nicotine reaches the skin and death is sure.

For capsid bug an ounce of strong nicotine (that sold as 95 per cent. is generally recommended) will make a dozen gallons of wash and 6 oz. of soft soap may first be boiled and turned into the water. The capsid bug is a wily creature and has a knack of dropping to the ground immediately a spray fluid approaches it. Therefore it is well to cover the tree with the fluid as rapidly as possible and then quickly turn the spray on to the ground underneath. If this is grass covered, give it a good soaking.

For aphis and caterpillar an ounce of nicotine is sufficient for 25 gallons of water, to which should be added 1½lb. of sulphide of potassium and ¾lb. of soft soap.

Arsenate of lead is a very powerful insecticide, and is of special value for spring use, but it is poisonous and a dangerous substance in careless hands.

Digitized by Google

If the winter moth has evaded grease bands and laid its eggs in the buds of fruit trees, an arsenate of lead wash will kill the larvæ. It is also capable of destroying the caterpillars of the currant moth and several other biting insects. Arsenate of lead pastes may be obtained ready made, and for private garden use it is wiser to use the preparations of the chemist than to corrupt pans and vessels with the poisons that may very easily do serious harm. When fruit trees show first signs of bursting their buds is the time to spray with arsenate of lead, but it must not be used where vegetable crops grow under the trees, neither is it safe to spray when wind may blow the fluid to neighbouring crops. In large orchards the use of so powerful an insecticide cannot well be dispensed with, but for private gardens where a few fruit trees grow amid vegetable quarters it is preferable to use something less deadly even though it may necessitate more than one spraying to achieve the purpose in view.

A lime-salt spray finds many advocates, and it certainly is cheap, safe so far as danger to life is concerned, and if properly made and carefully used it will do good work among aphis, mussel scale, apple sucker, etc., while as a winter wash it is capable of cleansing the bark of moss and slime. To make 20 gallons of lime-salt spray take 7lb. of common salt and dissolve in 10 gallons of water. In another 10 gallons place ¼cwt. of fresh lime. When thoroughly dissolved mix the two together, then strain through a fine gauze sieve, and the spray is ready for use. Lime-salt spray may be used right up to the time the flower-buds begin to open, but not after.

It will soon be too late for all the more powerful and penetrating fluids, but until young growth necessitates their dismissal the various mixtures here recommended are more effective than the softer soaps and emulsions that may be used with safety through the summer. Nicotine, of course, continues to be usable all through, and in fact it is my custom to add a teaspoonful to a knapsack of any soft soap and quassia or similar summer wash for roses and other plants. It is my belief that there would be far less trouble during summer with roses if they were sprayed with the nicotine-sulphur mixture during March. The egg-laying aphis works late in the autumn and early in spring laying eggs, on the stems and in the joints of old wood, that produce the first batches of greenfly that appear to come from nowhere. Spraying early by catching the first batches will go far toward keeping the roses clean well on through summer.

American blight dislikes this spray, and also paraffin, which is best used in the form of the proprietary brands of soluble paraffin, which can be mixed with water with greater satisfaction than is generally obtained from attempts to emulsify crude oil in soft soap.

Where one has but a small garden and only flowering plants to keep clean it is seldom worth while mixing up the ingredients, for the small canisters and packages of well known insecticides are ample if only the instructions supplied by the manufacturers are carefully carried out.

Failures arise from attempting to increase strengths, omitting to keep the solution well stirred or agitated, applying with inefficient sprayers, or delaying the use of insecticides until the plants are so badly infested that enough insects survive to repopulate the partially cleansed areas. Spray early, spray carefully and thoroughly, spray often. A. J. MACSELF.

NOTES FROM CONTRIBUTORS

WOOL AS A SEED DISTRIBUTOR.

ONE of the most remarkable collections of alien flora in the British Isles, possibly in Europe, is to be found, not in a delightful country garden, but in a black soot-besmirched northern manufacturing centre. On a piece of waste ground in the premises of one of Bradford's Corporation sewage works Dr. Druce of Oxford University, the famous botanist, had the pleasure of classifying more alien flora than at any other spot he has yet visited in a life-long devotion to botany and botanical research work, while Dr. Stelling of Zurich University, the famous German botanist and geologist, expressed himself amazed at the number of foreign plants found at the place in question. Mr. John Cryer, a local botanist, has from time to time found no fewer than 500 flowering plants, and for a time was at a loss to account for the presence of so many alien flora. However, investigation led to the discovery that the agency of distribution was wool. Seeds of plants indigenous in Australia, Argentina, Canada, etc., have come over to this country in consignments of wool, and in the scouring process these seeds have been washed down the drains to be eventually deposited on the "run away" ground at the sewage works. The exact locality of this wonderful flora is not stated for obvious reasons, botanists being very ardent collectors!—F. W. H.-E.

ANNUAL ASTERS.

IT is well known that these are among the most favoured flowers cultivated by amateurs for outdoor decoration in summer. Sometimes they are planted in mixed borders, also in rows or in small beds, and in all these ways they are easily grown and effective.

A succession of asters may be had by sowing the seed at different times. No time must now be lost in sowing the seed to produce the earliest plants and flowers. Place a few rough leaves at the bottom of a pan or small square box, and fill the remainder with a mixture of loam, decayed leaves and sand. Press this down firmly and then make small drills about 2ins. apart and 1in. deep with the finger. Sow the seed thinly in these and level the surface.

If the soil is damp do not give any water, but place the pan in a house with a heat of 50° or in a frame, and keep it close until the young plants appear, after which give air on fine days. As soon as the plants are large enough to handle prick them out into a frame, under a hand-light, or into pans or boxes the same as the seed was sown in. A little manure must be added to the soil at this time; this treatment will be found to furnish plants in excellent order for planting in their flowering quarters by the middle of May.

The ground in which they are finally planted must be open and rich, as it is an important matter to secure free growth at first to ensure fine blooms. I have no doubt many people will have seen the plants cease growing for a time after having been planted out and the leaves become curled as if attacked by green fly. This is the result of careless planting and poor soil, and although the plants may make a fresh start and then bloom, the flowers are never so fine as those on plants which were never checked. The plants need not be more than 12ins. apart. During dry hot weather they are greatly benefited by a mulching over the roots of short manure or grass from the lawn.

For late flowering the seed must be sown in May. I always sow the seed so thinly that the plants do not require to be thinned or transplanted from the seed bed until they are planted where they are to bloom. They suffer less in dry weather in this way than when shifted often. Watering has to be well attended to in the case of this sowing. Some plants throw up a cluster of flowers, but when the finest "show" blooms are wanted these must be reduced to two or three on a plant. Those who have no means of raising early plants need never fail in having plenty of late asters.—JAMES A. PAICE.

LATE-KEEPING CULINARY APPLES.

THE many conditions in which apples are stored are not conducive to their preservation, as, often, late season varieties are rotten long before their season (according to proper storing) is reached. A cool and somewhat ventilated storeroom is generally acknowledged to be the most suitable.

I saw, recently, a few specimens of well conditioned apples, the best being Annie Elizabeth; for colour and size this variety was admirable. Hanwell Souring, with skin greenish yellow tinged with reddish blush, is most useful as a cooker. The flesh is firm, crisp and briskly acid. The tree producing the fruit in question was trained as an open bush. Reinette du Canada, to my mind, should be extensively planted, especially as an orchard tree. It is strong and regular in its growth, and not so subject to canker as some varieties—at least, the trees I saw were forty years of age and as clean as one could wish. The fruit is large, somewhat broad and flat, but varies in form (one tree in the orchard produced nearly every fruit somewhat conical in shape); skin greenish yellow tinged with brown on the side next the sun; flesh firm, juicy and brisk, and quite good as a dessert sort in its season, this being in March until early April.

Norfolk Beefing is an apple that is, indeed, a real late keeper, the one drawback being that the trees are apt to canker on heavy or stagnated soils. Fruits about middle size, nearly round, colour deep red next the sun, with shadings of green on the underside; flesh firm and somewhat sub-acid. This is the apple Messrs. Gaymer of Attleborough bake and press without breaking and send out as a sweetmeat commodity. This variety succeeds as half-standards on light dry soils.

Sanspareil is a variety full of merit, and ought to find a place in every garden, as it is useful for dual purposes, keeping sound until May and even June. Fruit medium size, round in shape, colour yellow with red stripes, flesh firm and crisp, with every essential known in a culinary apple. The tree is compact in growth and very fertile.

Striped Beefing is a large late-keeping fruit of splendid cooking utilities. The tree makes a fine standard, and I am surprised this variety is not more in request. The flesh is firm and pleasantly sub-acid—in fact, an apple pudding I partook of lately, made from a fruit given me of this variety, was most enjoyable.—G. LOVELOCK.

CORRESPONDENCE

THE BREAKING OF TULIPS.

I HAVE read Mr. Needham's article on "The Breaking of Tulips," on page 156, and I have read articles on the subject by experts from across the Atlantic, and am induced to give my experience which may be of some interest to those who are studying the matter more deeply than I have time to do. I used to be troubled to a certain extent with my Darwin and Cottage tulips breaking and I carefully lifted all broken ones at flowering time and heeled them in separately, but still the trouble continued. I tried dusting the bulbs at planting time with green sulphur and isolating all the broken ones. This seemed to have the desired effect for I found no broken ones among the bulbs so treated. Now I dress all my bulbs in this way and I have every hope that the treatment has solved my difficulties. In a garden near here practically every tulip breaks the first year after planting and I have sent a number of varieties there for the purpose of experiment with the result that some interesting breaks have occurred. Now, I do not pretend to give any explanation of the cause of breaking, but it would seem that it is probably some fungus disease which is checked by the sulphur. I had a large batch of Boadicea broken the year before last. I lifted and dressed them with sulphur and quite a large proportion returned to their self colour again or, I should say, lost their stripes the following year. I would suggest that these bulbs were possibly but slightly affected by the disease, if such it be, and were amenable to the treatment, but it would be interesting to see the result of dressing some of the long confirmed rectified tulips; perhaps someone has done this already, if so, their experiences would be interesting I intend to try it. As to aphis, I seldom see them on my bulbs and when I do I give them as much insect powder as they require!—W. A. WATTS, *The Welsh Bulb Fields, St. Asaph.*

ANEMONES.

IN the article on Anemones by the late Maurice Hewlett (page 188), I see he refers to A. nemorosa as being difficult to transplant and that they only grow happily in woods. They grow wild in the woods here, but the best are in full open sun. The trees have been cut down and the ground turned up. The anemones have come up in thousands, as thickly as they can possibly grow. I find no difficulty as regards transplanting, provided the tubers (?) are not allowed to become dry—they will not stand long out of the ground like A. appenina without shrivelling. If they have to be kept, I usually pack them in damp peat moss litter.

The harebell blue Anemone nemorosa is mentioned. I grow six varieties, all of which I transplant successfully. The varieties are Celestial, Royal Blue, Cornubiensis, Robinsoniana, Alleni and Blue Bonnet. The first to flower here is Cornubiensis, and this is just showing through the ground now. Alleni is the largest and best, I think. Blue Bonnet is as large in flower but is dwarfer and very late, flowering long after the others. To see them at their best it requires a sunny day to open wide the flowers.—G. H. DALRYMPLE.

LONICERA NITIDA.

I AM down here for a day or two and have been looking at the Lonicera nitida hedge which I planted two and a half years ago and which you illustrated, as it appeared in November last, in your issue of February 2nd. Although out of seventy-seven nights since January 1st there has been frost—ranging from 14° to 2° of it—on sixty of them, and forty in succession up to this morning, the hedge wears a summer time look. Not only are the old wood and leaves wholly unaffected by the drastic variations of temperature between the icy nights and scorching days—with nothing constant except the keen dry north-east wind—but the new shoots are already developing, each showing three or four incipient leaves, which are bearing themselves just as bravely as their elders and, like them, are wholly unscared by frost. Indeed, in every part of it the hedge looks as if quite unconscious that there has been anything climatically disagreeable about this winter, which all my human friends complain to me so bitterly about.—H. AVRAY TIPPING, *Monmouth.*

THE BANANA PLANT IN WINTER.

IN THE GARDEN for October 6th, 1923, page 518, an illustrated article appeared on the banana (Musa japonica) growing in the open at Oxted. It was stated that protection was given during the winter

THATCH COVERING AS A PROTECTION TO THE BANANA PLANT OVER THE WINTER.

months by a thatched covering, which is put on in October and taken off in April. During the course of thatching, the plant is not cut down, only tied in to make a firm base, and supported by a tripod of poles, filled in with dead bracken and then thatched with straw. When the plant is uncovered in the spring the old stems are cut out and the young ones are just ready to unfurl their leaves, which soon respond to the sun and air, so that within a week or so the plant looks none the worse for its long hibernation!—R. C. JOLIFFE.

DELPHINIUM AS A NAME.

MR. ENGLEHEART'S interesting letter (page 194) gives, I think, the death-blow to the American delphinium story; but should some of your readers not agree, I may, perhaps, add the following evidence. There is very great doubt if the ancient Greeks recognised the colour of blue at all. Homer's "'dusky' violet," Virgil's "'black' violet" support this view; and Theocritus also speaks of the "sombre" colour of violets. The "cyanus" of Homer, which was probably an ultramarine enamel, is referred to as black. It was held by Max Muller that the appreciation of blue was quite a modern acquisition. Whether this be so or not, it is certain that blue is not recognised by the present Italian peasant. Mr. Norman Douglas, in his charming book on "Old Calabria," writes much about this point, and tells us that a cloudless blue sky is considered by the peasants "quite white," and the sapphire blue of the sea, which draws us from our Northern homes, is to them "colore morto," a dead colour.

All this seems to give little support to the theory that the favourite colour of the Greek deities was blue. As Mr. Engleheart says, it is extraordinarily difficult to identify the flowers or fruits of the early writers, and even the commentators on Dioscorides were unable to guess what plant he intended by Delphinium. The story of the dolphin looks suspiciously like a variant of the well known legend quoted by Pliny.—E. A. B.

SCRAPS.

RE Sir Herbert Maxwell's interesting remarks on rabbit-proof plants, the following may be of interest. We have an orchard containing apples, pears and plums. The trees were planted about eighteen years ago, and at first were protected with wire, the ground being cultivated. The wire gradually went and was never replaced. Three years ago in the spring the land was laid down to grass. During the autumn, circles were forked around all weak-growing trees, and within a week these trees were very badly barked, while those not forked were untouched. There had been no snow or frost. The remarks on "Tools" (page 173) is very timely, and if the people who buy them had to use their purchases we should then perhaps see the end of the heavy, cumbersome things now on the market. Why is not more use made of ball-bearings for wheeled implements at a reasonable price? In comparing prices of a ball-bearing roller and one of the other type I noticed a difference of £10 for the same weight. Ball-bearings would make a tremendous difference in a hilly garden.—"HIRED MAN."

PERENNIAL CONVOLVULUS.

IN his interesting note on the above (page 195), Mr. Canning-Wright recommends Convolvulus althæoides. I take it he refers to the plant usually listed under that name (which I believe properly belongs to another species), and, that being so, I can only congratulate him on finding it such pleasant company. I planted a root of this charming species in the rock garden and never have I been nearer the abyss of human woe than when I decided that the thing had to be extirpated. Its white, thread-like roots had gone through a flight of steps, burrowed under a flagged path, taken possession of a retaining wall (where they still are), and undermined the biggest boulders within a range of 8ft. from the parent stock. Days of work were involved in digging out the pest and yards of established rockwork and pathway had to be sacrificed. C. althæoides is admittedly a pretty plant and a good thing for a really safe place, but as a rock garden plant—no! The common bindweed, which Mr. Canning-Wright describes as a "terrible pest" is a mild affair compared with this vegetable octopus.—J.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Carrots.—Now is a suitable time to sow seeds for the main crop, selecting one of the well known intermediate varieties. Sow the seeds thinly in lines 1ft. apart, and well prepare the seed bed. After the numerous frosts that we experienced during February and early March the ground is in excellent condition; it rakes down to an even fine surface, and for the kitchen garden a wooden rake is far preferable to an iron one.

Peas.—If seed was sown in pots or boxes and placed in a warm glasshouse, the resultant seedlings should now be hardened off and set out in lines. Should the weather prove cold, protect them with evergreen branches. Further sowings of marrowfat varieties may be made; the second earlies are best at this period.

Turnip seed may be sown in lines 1ft. apart, and directly the seedlings are large enough they should be thinned or the crop will be ruined. Watch for the fly just as the seedlings appear and dust the rows with soot or lime early in the morning before the dew is dry.

FRUITS UNDER GLASS.

Vines.—In many vineries the work of stopping and disbudding will need attention, and the way such work is carried out will have a lot to do with the future welfare of the vines. Any superfluous shoots should be rubbed off gradually to prevent a check to root action. If the spurs are properly distributed, one growth from each will be ample, but there may be cases where two will be needed to fill up the roof space. When tying down the shoots to the wires, the grower should be patient, and not be in a hurry to get the shoots in position, or many of them will break, and often snap off at the base, thereby causing a gap. Two or three tyings will probably be required before the growths are in position. Each shoot should be stopped at the second or third joint after the bunch, according to the space to be covered, and here again a few ought to be done at intervals, beginning with the strongest and so on till the operation is completed. The early removal of superfluous bunches is most essential, and even in the early stages it can readily be seen which will be the best. With warmer weather more ventilation may be allowed, and the beginner should see that the top ventilator is opened an inch or so sufficiently early to prevent the foliage being scorched.

THE FLOWER GARDEN.

Annuals.—There is still time to make liberal sowings of annuals in the open border, and those sown in boxes early last month will soon be large enough for pricking off in a cold frame. When established, give plenty of air and gradually expose them to the elements in preparation for their final quarters in beds or borders.

Sweet Peas.—Seeds sown in boxes and pots early in the year have produced nice plants, and now they may be planted where they are intended to bloom. Clumps, where space is available are excellent; but, no doubt, rows 6ft. apart are the best where a quantity is grown. The stakes or other supports may be placed in position after the planting is completed.

Carnations.—Where the layers were potted up last autumn and have passed the winter in a cold frame, it will be advisable to plant them out in the open about this date.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Potatoes.—A sharp look-out should be kept on the border or borders in which the early potatoes have been set, and whenever the young growths appear above ground draw the soil up on either side and over them as a protection against frosts.

Seeds to Sow.—A further sowing should be made of the following brassicas: Brussels sprouts, borecole, broccoli and turnips. Where seeds of any other kinds have germinated poorly from earlier sowings, or seedlings have been destroyed, the losses should be made good now by re-sowing.

Vegetable Marrows.—Seeds should be sown in pots filled with loamy soil and germinated in heat, afterwards grow the plants in a genial atmosphere, until a frame is made ready in which to grow them. Long Green and Moore's Cream are two well known varieties.

Waxpod Beans.—Dwarf Waxpod or butter beans sown now in pots filled with a good potting mixture and brought on in a moderate temperature, will provide beans ready for pulling about the end of May.

THE FLOWER GARDEN.

Dimorphotheca aurantiaca.—The seeds of this beautiful hardy annual behave so badly that sometimes seedlings never appear. It is wise, therefore, to sow the seed thinly in boxes containing fine sandy soil and germinate under glass. Afterwards grow the plants as hardy as possible, but where protection can be given when frost threatens. When transplanting the seedlings to beds or borders, handle very carefully.

Lobelia.—Cuttings inserted some time ago and duly pinched to form bushy plants should now have filled the boxes. To have good specimen plants, space them out 2ins. or 3ins. apart into other boxes filled with light leafy soil. Place in a genial growing temperature until re-established; afterwards grow in a cold frame till bedding-out time.

Fuchsia Riccartoni.—This well known plant is usually to be found in most gardens. If not used as a hedge or screen, the plants should be cut over now, a few inches from the ground. It is easily propagated, and a large number of plants can soon be obtained by inserting cuttings in sandy soil throughout the month of July or even later.

Ten-Week Stocks.—The seedlings should be set out 2ins. or 3ins. apart in boxes filled with good soil and made moderately firm. Grow in a genial warmth and shade from bright sunshine until well established; then place in cold frames.

THE HARDY FRUIT GARDEN.

Wall Trees.—It is often the case that the soil becomes dry near the base of the walls where fruit trees grow. Water and farmyard liquid manure should be applied frequently to the roots of trees growing in such positions.

FRUITS UNDER GLASS.

Figs.—Continue to pinch the young growths at the third or fourth leaf. Liquid manure should be applied frequently to trees bearing fruit.

Vines.—The berries in the early house should now be sufficiently advanced to require thinning. Much care and experience are necessary before anyone can become an expert grape thinner.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Tecoma alata (syn. T. Smithii).—This plant is very useful for flowering during autumn and early winter. It is easily propagated by means of cuttings, which root readily at this time in a close case. The young plants may be stopped once if desired, but the best results are obtained by confining them to a single stem. Good plants can be grown in 5in. or 6in. pots, and they only require greenhouse treatment. In fact they may be grown in cold frames in the summer months, only using the lights during cold, wet spells. When the inflorescence—which is terminal—shows, all lateral shoots which develop underneath should be rubbed out. If this is not done the flower buds will drop off. This plant is somewhat subject to attacks by red spider and white fly. The former, however, should be easily prevented by a free use of the syringe, and the latter by fumigating with sodium cyanide, or some other approved remedy.

Cinerarias.—Where a batch is required to flower early, a pinch of seed should now be sown, giving preference to the more decorative, intermediate types, instead of the large-flowered florists' varieties. There are now good blue strains and rose-coloured varieties, both of which are very popular and effective for decorative work. Cinerarias should be grown under cool, moist conditions at all times, and during the summer months are best grown in low pits or cold frames. The potting compost should consist almost entirely of a good medium loam, because the growth is then much sturdier than when a lot of leaf-mould is used. These plants are subject to attack by aphis, which, however, can be prevented by frequent light fumigations.

Begonias. — Tuberous-rooted varieties that have been placed in boxes to start should, when they have made about three inches of growth, be placed in suitable sized pots. The potting compost should consist of a good mellow loam, and about one-third of leaf soil. Where eelworm has proved troublesome, the soil should be sterilised, as this is really the only preventive for this pest. Frequent applications of lime to the soil would probably do much to keep this pest in check. Dry tubers in store should now be started into growth in an intermediate temperature, while young plants raised from seed sown early in the year should be kept growing freely by giving them frequent shifts into shallow boxes. Towards the end of the month they may be planted out in cold frames.

Agapetes buxifolia.—This neat-growing plant, which produces its tubular red flowers very freely during the spring, is easily propagated at this time by means of half-ripened shoots. These root readily under a bell glass in a cool greenhouse. The plants thrive best in a compost of sandy peat, with the addition of a little light loam. While it makes good specimens in pots, it is seen at its best when planted out in a well drained bed in a cool greenhouse.

Pentapterygium serpens is another beautiful plant which succeeds under the same conditions as the above. It is, however, a much larger-growing plant, making long slender shoots. As it enjoys a considerable amount of shade, it is very suitable for clothing back walls that receive very little sunshine. This plant is easily propagated at any time by means of cuttings.

J. COUTTS.
Royal Botanic Gardens, Kew.

OBITUARY

MR. SYDNEY MORRIS.

By the death, at St. Jean de Luz on March 24th, of Sydney Morris of Earlham Hall, Norwich, the gardening world loses one of its foremost amateurs. He was the possessor of a remarkable power of judgment, not only as regards the merits of a plant, but also of its possibilities. Almost any race of plants that attracted his interest was certain before very long to yield seedlings showing breaks of colour or improvement in form. His name will always be associated most closely with the large-flowered strain of montbretias known as the Earlham varieties. Many of these have received awards when shown at Vincent Square and the Drill Hall; and those who had the chance of seeing the great beds of seedlings and selected forms as grown at Earlham could never forget the glowing mass of scarlet and orange, citron and copper, nor the enthusiasm of the master who had brought them to such perfection. He took up the raising of seedlings just about the time that the work was abandoned at Westwick, and, starting from the best of the Westwick varieties, soon added brilliancy of colouring and greater symmetry of form to their other good qualities.

Berried shrubs were one of his latest interests, and the large collection planted at Earlham was becoming one of the features of the place. The sprays shown at the autumnal show of the Norwich Horticultural Society were remarkably fine.

Mr. Morris had made a fine garden round his former home at Wretham, and after the destruction of the house there by fire sold that great sporting estate and moved to the historically interesting and charming old house at Earlham, for so long the home of the Gurneys, although it never belonged to them. There he laid out one of the most beautiful of modern gardens. The herbaceous beds, and the rock garden especially, are so well planned and planted that they are models of fine gardening.

At the annual general meeting of the R.H.S. this February the V.M.H. and the Veitch Memorial medals were bestowed on Mr. Morris. He had been for some years a most regular and useful member of the Floral Committee, and his taste and judgment will be as greatly missed by his colleagues as will his genial and cheerful presence by his many gardening friends. The little re-union of skilled amateurs and professionals who gathered under the hospitable roof at Earlham were some of the pleasantest events of the seasons.

BOOK REVIEW

SECRETS OF MANY GARDENS.

Mrs. PHILIP MARTINEAU, in her new volume, "The Secrets of Many Gardens" (Williams and Norgate, 12s. 6d. net), deals with many aspects of gardening and touches on conditions found on the Continent as well as in America. The work covers a wide range—somewhat too wide in the limited space at the author's disposal. Unfortunately, the work loses much of its charm owing to the treatment and arrangement of the subjects. One gets carried suddenly from a talk on peonies and dahlias, to find himself in the midst of a vegetable garden, learning all the details and intricacies involved in raising peculiar varieties; and then, no sooner has one settled there than he finds himself transported to a herbaceous border—from there on to the cultivation of dessert fruit. The reader gains nothing from this somewhat disconnected account. The later chapters are more or less general treating of the history of gardening, garden finance, gardening as a career, etc. The author is somewhat drastic in some of her ideas, but on the whole shows a deep insight into many aspects of garden economics. One illustration depicts what we are told is a "Scotch Fir." It is rather an unfortunate and a somewhat common mistake, as "Scotch Pine" is probably meant. The fir and the pine, as most people are aware, belong to two different genera, and such confusion of terms often arises.

To one who has a passing interest in gardening and horticulture, the volume will give pleasure and interest; but it does not supply any food for thought to the practical mind, save in so far as personal experiences with plants are described, and may serve as useful hints to anyone engaged in the cultivation of that particular species.

ANSWERS TO CORRESPONDENTS

MISCELLANEOUS.

How to Destroy Celandines (M. J. C.).—Every particle of root of the celandine plant should be removed from the soil if its destruction is to be complete in this way. A surface fire would be useless. If our correspondent can keep the beds free from bulbs and other plants for about three months from Autumn onwards, gas-lime may be used. Twenty-four ounces per square yard should be spread on the surface, left there for six weeks, and then dug into the soil as deeply as the roots of the celandine are found to be. In the spring following, border subjects may be planted safely. In the meantime, the regular hoeing of the surface soil will weaken the weed, causing it to bleed.

Name of Plant.—(E. V.).—Cornus Mas, "Cornelian Cherry."

Trial of Daffodils.—The Royal Horticultural Society will carry out a trial of the newer daffodils at Wisley during the next season and raisers are invited to send not fewer than three nor more than six bulbs of each variety they wish included to the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (if by rail, via Horsley Station, Southern Railway), to reach him by August 12th, 1924, at the latest. Only one-nosed (or apparently one-nosed) bulbs can be accepted for the trial and it is proposed to treat by the hot-water method all bulbs received unless they are accompanied by a certificate stating that they have already been so treated. The plants will be grown for two years or until it is possible to form a sound judgment upon their merit. At the end of the trial (which will not necessarily be at the same time for all varieties and which will be announced to senders), but not before, senders will be able, on request, to receive back the whole (or part, at their option) of the bulbs resulting from (or left after) the planting of the bulbs they sent to Wisley, but they will not be entitled to claim them after the end of September in the year in which the trial concluded. The necessary entry forms may be obtained on application to the Director of the Gardens.

FORTHCOMING EVENTS.

April 8th.—Royal Horticultural Society's Fortnightly Meeting (two days); lecture on the first day at 4 p.m., by Mr. M. Allwood, on "Carnations."—Jersey Gardeners' Society's Meeting.

April 9th.—Royal Horticultural Society of Ireland Spring Exhibition (two days).—Huntingdonshire Daffodil Society's Exhibition.

SAFETY FIRST!

Is the maxim of all good gardeners. Plants and trees need protection from the dangers of insect pests and diseases, but in giving them this you do not want to run the risk of injuring the growth. Give 'em

GYP

The Non-poisonous wash for plants and trees. It is the safest and cheapest on the market.

"Highly commended" by R.H.S. after exhaustive trials at their gardens, Wisley.

Obtainable from local dealers in pint tins, 2/-; quart tins, 3/-; and in drums and casks. If any difficulty write us direct (we pay carriage),

EDWARD COOK & CO., LTD., BOW, LONDON, E.3.

ADMIRATION

I MADE a purchase at the Show at Vincent Square on March 26th, a bush in full flower of a Japanese azalea called Hinodigiri. It came from Messrs. Russell and Co., Ltd. These are the bald facts which are always noted about a plant. It is now perched on a table in my flat where I can view it from every angle. From below I have to look, first of all, through the dark branches, then through a mellow glow like a sunset seen through the soft mist of wood smoke, finishing with dappled patches of fire where the lamplight strikes it.

It is a shapely bush, more than 2ft. in width, in an ordinary large garden pot; and I would not miss the pot for worlds. If it was seated in glazed pottery or in a bronze bowl, it would lose all feeling of simplicity; while the common pot, rather coarse in texture, suits it to perfection.

The number of blooms is uncountable: they are as the sands of the sea-shore. Each flower has five petals and five stamens, thrown out gaily in advance of the corolla with the style in front of all as an advance guard. The colour of the flowers billowing over the shapely bush is admirable, and the whole scene is in keeping. It is now more than a week since it arrived, and not a flower has withered or fallen.

This may sound egotistical, but my abode in this city is a flat within a stone's throw of a main thoroughfare; and that a plant, worthy of the name, should accommodate itself to these urban surroundings pleases me mightily. I have gazed upon it for minutes on end, filled with the most pleasant thoughts.

Here is a plant invented by the genius of the Japanese for their own particular purposes, and of a great age for a bush of its size, deigning to grace a European room, a room which is entirely utilitarian in its purpose. It is a great feat on the part of a plant and worthy of all praise. We are told that it is not quite amenable to our climate and requires a moderate temperature; yet imagine it in a conservatory surrounded by phalanxes of pelargoniums and cyclamens—admirable plants in their way, but how unsuitable to live alongside a Japanese azalea. These of all plants require to be admired on a pinnacle far removed from other flowers.

The Japanese have an extraordinary facility for placing plants in an ideal position. They make something more of them than ordinary garden furniture: their plants slip into their proper place and are obviously nursed and cared for so that they may fill such and such a spot in the garden or house. We are less exacting, and are satisfied with broad splashes of colour and massed designs.

Do we get full satisfaction from our plants? The mind of the Oriental works in wondrous ways, but on the whole he is simple in his tastes—just how simple it is impossible to guess. It is this simplicity which makes him evolve such weird and wonderful forms of chrysanthemums, for each individual bloom has to be planned and admired on its own merits. Every twist and angle of a petal has to suit the Oriental's particular idea of design, for the alignment of a plant means a great deal to the Eastern mind. In some degree his decoration is artificial, as in his distorted trees and meticulously arranged vases of cherry blossom; but at least he does not fog his vision by surrounding the main constellation with masses of satellites. He wishes to see cherry blossom at its best: very well, it is so placed that he can leisurely view it from all angles, without hurry and without restraint. Probably he is right, for he is not in the position of the man who cannot see the wood for the trees.

True admiration does not come from a hasty glance; it requires much time and deep thought. Justice must be done, and so the subject must be viewed from every aspect.

There is an ordinary every-day proverb which says that familiarity breeds contempt. Unfortunately it is true. Who knows but that an ordinary artichoke or a well grown plant of rhubarb may not be worthy of respect, if it is placed in an atmosphere suitable for admiration? It is not only possible but probable.

Epilobium angustifolium, the common willow herb, is often a curse in our gardens, but I well remember seeing an acre or so of scrub which had been cleared by fire the year before. The willow herb had come up in its legions and was in full bloom. Viewed in the mass with a background of birches, it was enchanting. That is the one picture, a noxious weed in a setting to suit it. On the other hand, everyone knows that the most perfect rose is dwarfed into obscurity in an atmosphere of old cabbage heads.

But this article leads nowhere. It is not meant to be a treatise on how to utilise our garden plants to better advantage, nor is it meant, to use another proverb, to teach our grandmothers to suck eggs. Rather is it written in a vague manner to show how admiration depends upon the suitability of a plant for its immediate surroundings. One plant in particular, has of its own ability taken possession of a room. The plant is pleased, and I am full of admiration. What more can any plant want?

E. H. M. C.

A SMALL ROSE GARDEN

BY M. J. M. VICARS-MILES.

I AM aware that the object of THE GARDEN is to show its readers the very best way in which things ought to be done, therefore to put forward anything less than that may seem somewhat useless. There must, however, be many lovers of gardens who might like to hear of the struggles of a comrade whose object is to get the greatest amount of satisfaction and beauty out of an all too shallow pocket and to make as sure as is possible of a certain return for money spent.

To begin with, I have tried in a small way to grow roses for thirty years, beginning with about 100 and increasing later to 600 or 700. First of all, filled with enthusiasm, I bought in twos and threes the roses advertised by rose growers in the most glowing terms. This was an expensive and unsatisfactory method for many obvious reasons. Some were strong-growing, some were weak plants. Some liked my soil, others would not have it, and if once a rose declines to thrive in a certain soil no amount of care and trouble seems to be of much avail.

A later plan was to arrange different coloured roses in larger beds by tens or dozens. This, though an improvement, was not entirely satisfactory. I do not mean to say that a great deal of loveliness and pleasure did not result. However, the last stage of my rose growing, the arrangement of which was not my doing, certainly has given me greater satisfaction than any other. Some years ago, like many others, it became evident that a smaller habitation was necessary for me, and I had sadly to turn my back on my old garden. However, by very good fortune I found a house and garden whose owner was evidently as great a lover of flowers as myself. What it must have cost him to hand over his garden to me! One of the most tempting things in it was a rose garden, evidently originally levelled as a tennis lawn. It was surrounded on three sides by a low, well grown yew hedge, while a belt of firs protected it on the north side. This garden contained twenty-two rose beds. Sixteen of them had about twenty of one particular rose in each of them, while the six centre beds running parallel (three on each side of the centre broad grass path) were filled with standards rising out of dwarf polyantha roses. In another part of the garden were three rather large beds holding now about fifty roses apiece. To confine myself to the rose garden, it seemed to me that my predecessor had, like myself, been weaned from the desire of acquiring novelties, for the sixteen beds were planted as follows: 1, Hugh Dickson; 2, Mrs. Herbert Stevens; 3, Mme. Edouard Herriot; 4, Mme. Abel Chatenay; 5, Lieut. Chauré; 6, André Gamon; 7, Mme. Jules Bouché; 8, Lady Hillingdon; 9, Richmond; 10, Lady Pirrie; 11, Frau Karl Druschki; 12, Château de Clos Vougeot; 13, Mme. Mélanie Soupert; 14, Mrs. Wemyss Quin; 15, General McArthur; 16, Caroline Testout. The standards in the middle beds are chiefly single specimens of the above. These are all good old "chestnuts," and scarcely one would be found now in a rose grower's list in an advertisement to attract the buyer. My chief object in writing this is to state my reactionary opinion that (eliminating perhaps four of the above list) it would be impossible to get a better feast for the eye and nose than can be obtained from these old stagers. Perhaps my antagonism to a semi-double rose vitiates my opinion, and so many of the modern new roses appear to me to suffer from looseness and floppiness, and also the present object seems to be to seek after vivid rather than pure colour. Some twenty years ago an old rose grower who was very successful at the shows told me that for form he considered a well grown bloom of the old A. K. Williams was ideal. I think his opinion now would be received with scorn.

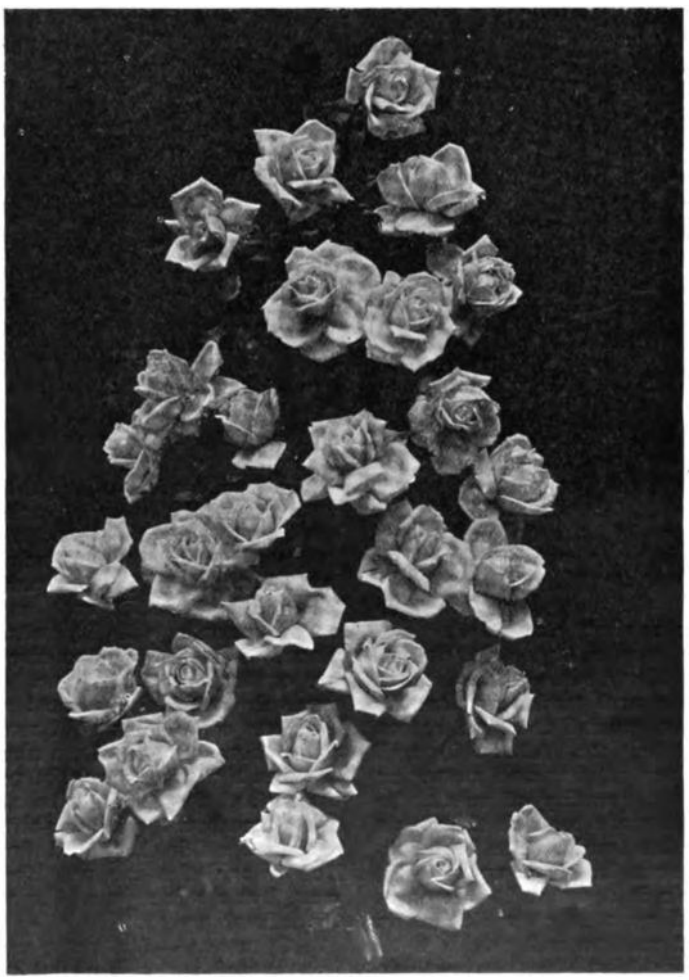
I should like to say a word or two about the roses I have named. First, Mme. Jules Bouché is one of the best, though it is dubbed "blush" in the catalogues. With me it is as white as Frau Karl Druschki except for an occasional blotch of pink in one out of five blooms. It is gloriously scented, of beautiful shape, and very generous in bloom and continuity. Mrs. Herbert Stevens, though more of a "bud" rose, is still more generous, and I have picked a bowl of good blooms in November. Mrs. Wemyss Quin is the best yellow I have ever grown, and I think I have tried most yellows. It is very healthy and disease proof. Lady Hillingdon always responds most heartily to one's efforts. I regret very much I cannot grow Mme. Abel Chatenay. It was dying out when I came here, and as in former years I had replanted a bed of fifty only to fail, after two years I expelled this rose from the rose garden.

If she be not fair to me,
What care I how fair she be.

I wanted to replace it by another old rose, Antoine Rivoire, but I yielded to the persuasion of a well known rose firm and put in Henrietta, and have regretted it ever since. Château de Clos Vougeot also did not succeed too well, and I replanted the bed with another old rose, Laurent Carle. With beds of twenty to twenty-four roses of the same sort casualties spoil the effect. When another shilling comes off the income tax I shall replace Druschki and, I think, Richmond. The first because it does not interest me, and the second because of its lack of vitality. Mme. Herriot I keep because it does extraordinarily well and others like it better than I do.

The two things I find very essential in treatment are: (1) Keeping the Dutch hoe going constantly but very carefully. I say carefully, for a touch of the hoe on the rose stem I have found does great damage. (2) Spraying and dusting. Green fly must be fought and fought early, and I find Mr. Pinches' Patent Dust Gun, recommended for dusting sulphur in the National Rose Society's book, is invaluable for keeping away mildew and black spot.

I do not entirely approve of the dwarf polyantha roses in the middle beds and would like to see another 100 dwarf hybrid teas there, but being there they must stay for the present and the effect is



AN EXCELLENT ALL ROUND GARDEN ROSE, HUGH DICKSON.

Digitized by Google

A PRETTY DECORATIVE ROSE, LADY HILLINGDON. BRIGHT YELLOW IN COLOUR AND A VIGOROUS GROWER.

ONE OF THE BEST FOR ALL PURPOSES. CAROLINE TESTOUT, WITH WARM PINK FLOWERS.

certainly pleasing. In pruning these I do not take the advice of the National Rose Society's manual, but cut right to the ground as advised by the rose grower from whom I first purchased my roses. Having tried both ways, I have no doubt as to which has the best result.

To sum up, my advice to the small rose grower is: (1) Seek pure colour; (2) choose either single or double and eschew the floppy varieties; (3) choose generous-growing roses that will not let you down; (4) satisfy both senses of sight and smell.

I have not said anything about the three beds of fifty roses in another part of the garden. They are without system but very useful for keeping old favourites whose blooms I still want to see and also for the occasional trial of a novelty. Casualties do not matter so much in a large mixed bed. Also these beds save the rose garden from depredations at the hands of the ladies cutting flowers for the house!

POPULAR DAHLIAS

PREPARATION OF THE SOIL.—Those contemplating making a feature of dahlias in the garden should begin preparing the ground in autumn or winter. Any piece of good garden ground, neither too light nor inclined to clay, and well drained, either naturally or by artificial means will grow dahlias. When new ground is being converted for this purpose, it is well to trench it 2ft. or 3ft. deep, and incorporate some manure between the spits. What is worth doing is worth doing well, and the gardener may rest assured that well prepared beds or borders will last or be used for growing dahlias for an indefinite number of years. Many of the old school of successful growers, both nurserymen and gardeners, used to plant their dahlias on borders or on ground that had grown this class of plants for twenty years or more. After being well trenched at the commencement, deep digging and manuring may serve for many years. A large quantity of manure is undesirable, because, if the ground is made too rich the plants will grow unusually tall and flower less freely. The best plan is to dig and manure it in the autumn, laying it up roughly, so that rain and frost may crumble it down and sweeten it during winter. One is often called upon to grow dahlias in light soil, but plenty of depth and manure will rectify that. Heavy soils can be made more open and friable by dressing them every year at the time of digging with gritty road sweepings, river or pit sand, and using rank stable manure. A dressing of newly slaked lime once every three years will also help in the same direction.

PROPAGATION.—The dahlia may be propagated from seeds, cuttings, divisions in a variety of ways, and sometimes by grafting. Seeds of a good strain, belonging to any class may be sown during March or early in April, in pans, pots or shallow boxes, according to the quantity to be reared. Any sandy soil and leaf mould, such as is used for the rearing of half-hardy annuals, will be suitable. The seed pans should be placed where they will receive a bottom heat of 60°, either in a propagator or a close case. A system which used to be extensively pursued by most raisers of dahlias was to place the pans on a hot-bed of manure, where the heat and moist atmosphere brought them along quickly. When the seedlings are 2ins. high they should be potted singly in small pots. When established they should be allowed to stand on the benches of a warm house, given a shift into 4in. pots when well rooted, hardened off in May and finally planted out early in June. Double varieties are not likely to reach perfection the first year, but a selection of the very best may be made for trial the following year.

CUTTINGS.—The most usual method of propagating the fine, named varieties of dahlias is by cuttings. A commencement may be made during February or March by planting the old roots in light sandy soil on a mild hot-bed, or in pots or

boxes, leaving the tops or crowns fully exposed. Some gardeners plant them in sandy soil under the benches of a warm house near the hot-water pipes. Anyone can adopt a plan that is most convenient. The soil used should be suitably moist and if it becomes dry it may be lightly watered, with a rose or a syringe to encourage the tubers to commence growth. When the shoots are 2ins. or 3ins. long they may be removed with a sharp knife close to the tuber, and inserted singly in thumb pots filled with sandy soil, or five or six round the edge of a 5in. pot, with a layer of silver sand on the top in each case. The pots can now be placed in the bed of a propagator or in that of a hot-bed where they will get a bottom heat of 60°, assisting the rapid formation of roots. When well rooted they can be potted off singly in 3in. pots and grown there till the pot becomes too small, when they should have a shift into 5in. pots. A good rich soil should be used for both pottings and the plants well exposed to light in a warm house. As soon as they are established in the larger pots, or early in May, provided the weather is genial, they should be transferred to a cold pit or cold frame, well hardened off towards the end of the month and planted out early in June, or as soon as the weather will permit without the necessity of protecting the plants at night with inverted pots.

DIVISIONS.—Where the quantity required is not large, or where the convenience for rooting cuttings is not great, recourse may be had to division of the tubers. Even for this process some means of heating will be necessary to start the old tubers into growth, because it cannot be seen where sprouts will arise until growth commences. Young growth can only come from the top of the tubers, where they join the base of the old stem. The young shoots just appearing may be ½in. to 1in. long or more, and they can be removed with an inch of the old tuber or even less. This piece of tuber makes the sprout certain to grow into a plant, even if only sun heat is available in a greenhouse or frame. This makes it possible for anyone to propagate dahlias by division during April. A box may be filled with roots, another box placed over the top to preserve the moisture, and, if put where a kitchen or scullery fire will give a little warmth, the roots will gradually commence growth. An outhouse or cold frame will give the necessary protection during May, providing the growing divisions can be well exposed to light. Sometimes the old roots are planted out whole during May, but such do not make good flowering plants unless they are severely pruned, leaving two or at the most three stems.

Grafting is sometimes performed in autumn to save a new or rare plant in case the root should die. A thin slice is taken off the side of a cutting, and another similar slice from a tuber. The two are tied together so that a good union is ensured. The point of union of the stock and scion is then covered with clay and potted so as to protect the base of the graft. The pot is placed in bottom heat till a union is made, and the plant kept growing in heat all the winter.

PLANTING.—It is generally safe to plant out dahlias during the first week of June, if they have been previously well hardened off by exposure to the air. A sunny position is imperative if the best results are to be obtained. Whether in beds or borders they deserve a prominent place in the garden. The ground, if properly dug level and broken up finely need not be raked unless it is rough. Lay the garden line and mark off the space to be planted at 3½ft. or 4ft. apart, allowing the second and fourth lines to alternate with the first and third. It is a good policy to drive in the stakes first, behind the line, and exactly straight. Then lift the line and dig a fair sized hole in front of each stake, adding a spadeful of well rotted manure and plant the dahlias a little deeper than they were in the pots. The after-treatment consists in hoeing the ground frequently, watering heavily in dry weather, thinning and tying the shoots as required. Fine bushes can be made by driving a smaller stake on each side of the main one, and fixing a good side branch to each. Earwigs are the chief enemies of dahlias and should be trapped as soon as they are detected or earlier. J. FRASER.

(To be continued.)

HARDY HYBRID RHODODENDRONS

DURING the past twelve months a great deal has been written about rhododendrons, and, probably, among the devotees of the great genus discussion can scarcely be said to be final; indeed, it resembles Tennyson's brook, going on for ever! Looking back over the period during which I have been personally interested in the subject, I have never known a time when so great an interest was taken as the present. This I look upon as being a happy omen for the future. Each additional devotee to the subject furthers the general interest. The introduction of many new species by Wilson, Forrest and other great explorers has given a new impetus to the interest in rhododendrons, and undoubtedly, with the large number of persons actively engaged in the work of hybridisation, in a few years our gardens will contain many beautiful hybrids of a type quite distinct from those with which the general public are now familiar.

I see no reason why there should not be a fine race of really late rhododendrons extending our present flowering season well into July. There is no difficulty in raising fine hybrids in the early-flowering section. There are so many beautiful species which can be drawn upon, and indeed there are in existence a large number of very beautiful kinds of what may be called early flowering as compared to the season when the great mass of hardy hybrids come to perfection. But, alas! the general public rarely sees this class of rhododendron in perfection. In order to do so one must visit the western coasts, where the influence of the Gulf Stream is sufficient to temper the more severe conditions prevailing in our inland and eastern counties.

The amateur with a garden suitably situated in our southern and south-eastern counties can get fairly good results with a number of hybrids and species which from a general gardening point of view must be looked upon as being tender plants, subject to damage sufficient in certain seasons to kill them completely. It is evident that, such being the case, the intending planter should obtain the best advice as to what species or hybrids are likely not only to survive but to thrive in his particular locality. Personally, in visiting gardens, nothing annoys me so much as to be shown a miserable plant struggling for existence in a climate quite unsuited to its constitution

CHARMING TRUSSES OF ONE OF THE HARDY HYBRIDS

Digitized by Google

and which its owner proudly tells me is the only one in the country.

In dealing with the question of hardiness of any plants, the selection of the right site in a garden is of the greatest importance. Woodland planting of rhododendrons, where practicable, is by far the best. Fortunately, they thrive well under trees provided there is not too dense shade, in which case, although they might thrive in a growing sense, the flower would be scanty and possibly of poor quality.

The ideal position is in a wood, fully matured, which has been thoroughly thinned, and the trees allowed a fine head development and where there is considerable head space before reaching the branches. Side shelter to prevent such a wood being draughty is essential, and should be as dense as possible. Under such conditions it is possible to grow many plants which, if planted outside the wood, would rarely give satisfactory results. I consider the protection afforded to rhododendrons in these ideal conditions represents, in still, frosty weather, a difference of 8° or 10° of temperature.

The winter frosts, unless very severe, and such as we experienced in 1895, when several nights the thermometer registered well below zero, do not injure rhododendrons so much as the frosts we get prematurely in November, before the plants are thoroughly dormant, or in spring, particularly through the glacial period, when they have become active again and the sap is up. These frosts, especially when there is a certain amount of wind, are very penetrating and do a lot of damage. The spring frosts are very annoying, as they usually time their arrival at the moment our most treasured specimen is about to bloom. I have noticed in recent articles about rhododendrons a tendency to eulogise the species and more tender forms of hybrids. I admit their charm and beauty in their proper sphere, but I cannot help feeling that many people are sadly misled and are induced by the glowing description to plant them without any thought as to the suitability of the proposed planting. I am, of course, specially interested in hardy hybrids, and can speak with a certain amount of knowledge on this particular branch of the rhododendron family. Bagshot has been responsible for sending out a large number of recognised and tried favourites suitable, for the most part, to planting in any garden in the British Isles where soil conditions are favourable, and it has been always our great aim to retain as far as is possible a completely hardy breed. Perhaps the most famous hybrid we ever raised is Pink Pearl, which combines hardiness on the one side with the beauty of form generally associated with the more tender section of hybrids emanating from the same origin on the other side of the cross.

There has been from time to time a lot of discussion as to its real origin. I may say that it originated in Bagshot from a cross made by the late John Waterer, my father, and I was left to introduce it to the public. Few plants of any kind are better or more widely known than Pink Pearl. Among the majority it is greatly admired, and it is certainly largely planted, but it has its unfriendly critics! Indeed, there may be said to be two schools of rhododendron fanciers, to one of which Pink Pearl is anathema and to the other the "Queen of Flowers." I submit that poor Pink Pearl is a crumb from the rich man's table, and "Lazarus"—in this case the rhododendron fancier whose garden is not in the most favoured locality—has much to be thankful for. Other hybrids somewhat of the same type have followed, but none has yet deposed Pink Pearl from its position as the finest of *truly hardy* hybrids. Nobody would venture to prophesy as to the future, but I believe it will hold its position for some years. When I reflect that some of the most popular hybrids to-day, such as Michael Waterer, John Waterer, Lady Eleanor Cathcart and others, were introduced by my grandfather, it is not to be wondered at that I should say Pink Pearl will still be a favourite in another fifty years.

A WELL-FLOWERED BUSH OF RHODODENDRON PINK PEARL, AMONG THE FINEST OF HARDY HYBRIDS.

I hope I shall not give any offence to those brilliant amateurs now interested in the genus rhododendron, and I hasten to say that my notes here are not addressed to them, but rather to those to whom a fine group of rhododendrons appeals but who lack any special knowledge as to what to plant and where to plant it. To them I would say, "If you think you have the right sort of garden or woodland garden to grow the species and more tender hybrids, by all means plant them, but do not forget to add some of the best of the hardy hybrids, which will give each year a brilliant finish to the flowering season; and if your garden is not of the most favoured, be content with the less grandiose of the rhododendron family and be duly thankful for these."

F. GOMER WATERER.

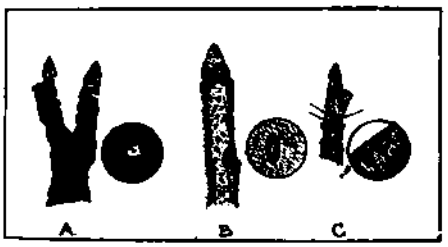
SYMPTOMS OF DISEASE ON GARDEN PLANTS

NOW that spring is with us, when all life, both in the animal and plant world, is awakening from its winter sleep, and the gardener and fruit-grower are busily engaged in their respective duties, it is advisable



INSECT EGGS, SHOWING METHODS OF DEPOSITION
A, Apple sucker; B, aphis; C, red spider.

to make a few remarks on several of the more common pests which one comes in contact with throughout the spring and summer in any average garden or orchard. In these days, when the study of mycology, plant pathology and entomology is becoming increasingly important, and with the advent of many diseases new to this country, it is well that the average man should maintain a strict look-out for the occurrence in his garden or orchard of any attack of disease on his plants, bushes or trees. Every facility is now being given to the business man who may have a passing interest in horticulture to familiarise himself with the many aspects of plant disease, and it is to be hoped that the energies of men engaged in the pursuit of knowledge, will lead us to a better and wider understanding of how the many causes act on the host and how disease is transmitted. Mention might be made of the invaluable assistance and help, in the shape of publications and leaflets, afforded by the Ministry of Agriculture to all those engaged in cultivating the soil to the best advantage. These leaflets contain much useful information served up in a form which is palatable to all, and are excellent as works of reference.

The question of immunity from disease is one of exceptional interest and importance, and would require at least one, if not more, separate articles. One point worth mentioning is the question of the native habitat of a plant, if it be a new introduction. These introductions to the flora of this country—if taken up by the gardening public and, hence, undergoing intense cultivation—are liable to the attack of many diseases which apparently spring into being as a result of the increasing numbers of the new host. Climatic and topographical conditions are also important from the point of view of spread of a disease.

I think, perhaps, it might now be well to examine a few points, giving the general symptoms of insect and fungoid attack and so enable one to determine the agent at work as far as is possible from an external examination. It may be stated at the outset that the greater part of the damage done to fruits, garden plants and vegetables is the work of insects and that few plants are immune from their attacks.

The number of genera and species of insects is enormous and the diversity of their food is only exceeded by their variation in form. Most insects exhibit the same metamorphic changes. One finds in the majority of cases, and especially in that of the lepidoptera, *i.e.*, moths and butterflies, that four entirely different morphological forms are met with. Two active and feeding stages are found alternating with two inactive and non-feeding stages. The active stages are the important ones from the cultivator's view-point, as it is in these conditions that the insect can be best attacked and destroyed. In the case of the moth, these forms are the caterpillar and the adult moth, and it may be well at this point to distinguish between these two in the mode of feeding. The former obtains its food by biting and the latter by sucking. Thus we have created an important division, enabling one to distinguish damage performed in the garden: (1) Those which, by biting, extract entire portions of the plant, and (2) those which pierce

PEA AND BEAN WEEVILS.
Typical examples of the biting group.

the tissues of the host plant by means of their proboscis and extract their food by sucking from the interior of the plant. In the first case it is possible to kill the insect by spraying a poisonous solution on the plant, but in the second this cannot be done, as the plant as well as the insect would be killed, since the poison would require to enter the tissues of the host itself to prove in any way destructive to the insect. In some cases the former method does not apply, as, for example, with those caterpillars which bore into the tissues of the host and those which live for the most part underground. In the majority of cases, however, this distinction is of enormous importance, serving to show one how best to attack the insect. The larvæ of butterflies and moths, beetles, sawflies, and two-winged flies, come under the first category; also adult weevils, wasps and ants. Into the second class fall scale insects, aphides and two-winged flies in the mature stage. In order to deal in a proper manner with a pest it is necessary that the life-history of the particular insect under discussion should be known. From that one can then determine at what period in its life cycle the insect is most open to attack by the application of an approved insecticide. In this way, then, can the success of an attack and ultimate destruction of an insect pest be brought about.

The presence of insects in a garden or orchard is generally easy to detect, and where insects are suspected, a search should be organised to weed them out.

When clean-cut holes are found in the tissues, caterpillars, larvæ of sawflies, grubs, beetles or cockroaches, may be suspected. Weevils, *e.g.*, pea and bean weevils, are generally found to cause damage by eating away the edges of leaves, and the bark in the case of seedling trees, *e.g.*, pine weevil. Boring in stems is characteristic of the larvæ of many moths, *e.g.*, goat moths and bark beetles, raspberry moths, etc. Blisters may be caused in the foliage by many flies, such as the celery fly, chrysanthemum fly and also by a few caterpillars. The damage of the carrot fly is characteristic—the larvæ tunnelling in the tap root. Roots are also destroyed by wireworms, chafers, etc. When one finds tunnelling in the fruit it may be caused by the larvæ of moths or sawflies. The apple moth and tomato moth are to be found holing the fruit. Flowers are oftimes devoured by many chafers, while destruction of buds is carried on by the carnation fly and bud moths. These symptoms referred to are all more or less produced by the biting group. On the other hand, scale insects often cause minute holes accompanied by a puckering of the leaves and a consequent discoloration. Honeydew is generally present in abundance on plants affected by green fly. One-sided growth in flower-buds is in many cases due to the puncturing of the stem by a scale or bug. Many woody plants show stunted growth and curving shoots due to an attack of a scale.

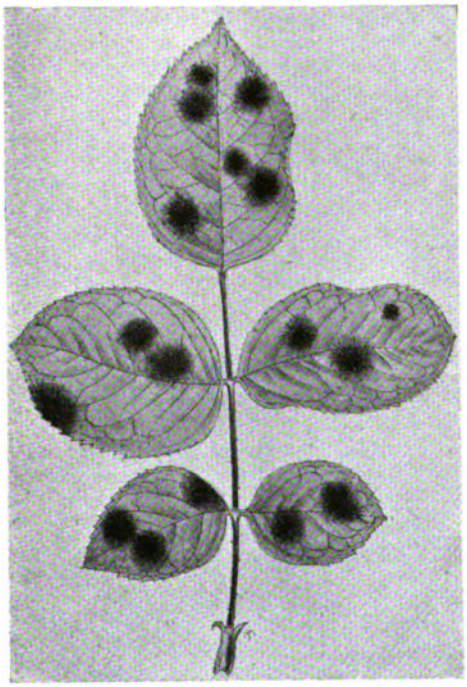
From a general point of view it may be mentioned that one often finds what are popularly known as "galls" produced on many plants, of which the oak is the outstanding example. These are caused by irritation set up by gall flies. The interest in galls lies in their multitude and their variety of form, shape and occurrence. In a few cases the presence of an insect can be determined by its excrement or by frass—fine sawdust—lying about (the latter if it is a wood borer). In a more or less superficial way, then, I have tried to present a short *résumé* of the

THE CELERY FLY.
1, Celery fly; 2, grub; 3, chrysalis.

Digitized by Google

nature of the damage caused by insects on plants. In most of the above cases the insect is wholly parasitic on the plant, at least during one part of its life-history.

For the sake of comparison I will endeavour to run over in a brief way the appearance of fungus attack on plants. Now, as everyone knows, the fungi belong to the lowest group of our plant life. They are characterised, by forming what is known as a branching mycelium made up of thin strands called



ROSE LEAF ATTACKED BY BLACK SPOT, SHOWING THE CONSEQUENT DISCOLORATION.

hyphæ; and by being destitute of chlorophyll—the green colouring matter found in all other groups of plants, although often overshadowed by the presence of other pigments, as in the case of the red seaweeds. Since this colouring matter is absent, which in the ordinary green plant supplies the necessary energy whereby carbohydrate food material in the forms of sugar and starch is manufactured, the fungus must create some other mode whereby it can flourish, and consequently it becomes a parasite—or a saprophyte. The former term is applied if it absorbs its food material from a living host, the latter if the host is either decaying or dead. It is being proven slowly that most of our parasitic fungi are facultative, *i.e.*, they can become saprophytes under certain conditions, and this is a point of extreme importance when tackling the disease.

Diseases due to fungi are, in general, characterised by the formation of spots of various colours on the infected parts of the plant. These spots may be due to the aggregation of the spores of the fungus on the surface of the plant or to damaged cells caused by the hypertrophy of the tissues due to the presence of the fungus. Increased growth may also be a result of a fungus attack. Environmental conditions, such as a suitable temperature and moisture, are necessary for the proper development of the fungus and for its spread, and if the suitable host be present in sufficient numbers in the vicinity, the attack may resolve itself into an epidemic. One should be careful in the interpretation of a disease, as many fungi are secondary, *i.e.*, one fungus, having caused the death of an organ, disappears, its place being taken by a secondary fungus, which can be seen. It is better to follow out a fungus in all its various stages before one reaches a definite conclusion. It should be grown through its life cycle and then used to reinfect the host from which it was collected in order to see if the same symptoms are produced. It may be said here that identification of a fungus can only be carried out with accuracy if the spores are found. Certain fungi *e.g.*, the rusts, a group by themselves, spend part of their life on one host and the other part on a second host. The stage found on the first host will not be found on the second host. This is an important point to look out for when dealing with a fungus pest, as the attack may be met by destroying all the host plants of one stage of the fungus. Many of the common weeds act as the alternate hosts for these fungi. All these phenomena

ONE OF THE MANY HOSTS OF STEREUM PURPUREUM, THE FUNGUS CAUSING SILVER LEAF.

go to make the study of fungi an intensely fascinating as well as important branch of botanical science. G. C. T.

GREENHOUSE PRIMULAS

DURING the last ten years or so these plants have been considerably improved, and now they occupy a foremost position among greenhouse flowers that make such a bold display during the winter months. There is a wide selection to choose from, the colours are both varied and attractive, while the foliage of many is an additional charm.

No doubt the most decorative section of primula is P. stellata, a free-flowering group which remains in full beauty for quite a long period. Among the best will be found Sutton's Silver Star, a pure white variety without the usual "eye," and dark foliage which makes a pleasing contrast. Another exquisite form is Ruby, a rich crimson which is intense even on the dullest day, and no doubt it is one of the best. Coral Pink is indispensable; the flowers, a rich, creamy pink, are freely produced, and the reddish tinge in the stalks of the leaves renders the plant more beautiful as a whole. Both the Light Blue and Dark Blue are good, but Enchantress did not please me nearly so much as the above. There is even a wider selection among the large single primulas than in the stellata section, but they are rather stiff in appearance, and for this reason are not favoured by some growers. Most firms of repute have a list of varieties in their catalogue, and Giant White, The Duchess, Etna, Coral Pink and the various shades of blue are all desirable kinds. A good mixed strain of P. obconica will produce a fine display in the winter and spring months; but for those that object to mixed colours there are shades of pink, crimson, blue, white, lilac and salmon, which can be relied upon to come true from seed. P. malacoides is such a dainty primula that it is well-nigh indispensable, and if a little seed is sown at intervals of about eight weeks the flowering season is considerably extended. The flowers are lilac or pale mauve, and there are several improved forms in commerce, but I hope the type will be preserved. Quite distinct in colour is the delightful P. kewensis, which bears flowers of a rich yellow colour, and a batch of well grown plants when in bloom is exceptionally fragrant. A pretty little plant is P. Forbesii; it is a charming miniature half-hardy species with rich rosy-mauve flowers with a yellow eye. It will bloom in a three-inch pot, therefore occupying little space.

All the primulas mentioned are raised from seeds which are sown during May and June; but P. obconica may be sown a few weeks earlier if flowers are required during the autumn months. Clean, well drained pots or pans are chosen, and filled with a mixture of loam and leaf-mould with a moderate

Digitized by Google

sprinkling of sharp sand. Water well a few hours before sowing the seeds. Sow the seeds thinly, only a slight covering being needed, and place the receptacles in a warm greenhouse where the temperature is about 60° Fahr. A piece of glass placed over the top of each pot or pan will prevent the soil from becoming dry, while shade will be necessary when the sun is bright. Under such conditions germination will be fairly regular, and when the seedlings appear the pots should be placed near the roof glass to prevent the growth becoming weak and spindly. When the seedlings are ready the largest may be placed singly in 60 size pots, and the smaller ones pricked off in pans or around the edge of a pot about 3ins. in diameter. A brick pit will suit them best at this stage. Afford water in moderation, and protect the young plants from strong sunlight; but there is no necessity for the shade to be dense. A little air should be admitted during the day, also at night when the roots have taken possession of the soil. In a few weeks the pots will be filled with roots, when the plants will be ready for their final potting. The majority will go into pots 5ins. in diameter, and a few of the best examples may be given a size larger. Good drainage is essential, and the pots should be clean both inside and out.

The rooting medium consists of fibrous loam three parts, and one part leaf-mould, with a liberal sprinkling of lime rubble and sand. When repotting, make the soil moderately firm, and see that the roots are low enough for the top of the plant to be made secure without the assistance of a small stick. If properly potted and grown cool, these primulas never need staking.

Cold frames not exposed to the midday sun will suit the plants after their final potting until the nights become too cold, when a cool greenhouse is all that is required.

Primulas enjoy at all times a cool bottom, and if the staging is covered with a layer of ashes or gravel, it will prevent the roots from becoming dry at short intervals.

Throughout their existence careful watering is advisable, and after the seedling stage every effort should be made to grow the plants as hardy as possible.

PRIMULA STELLATA CORAL PINK.

Insect pests are not troublesome, but green fly often appears, which can easily be destroyed by light fumigations. It is imperative that this pest is never allowed to make any headway or the young leaves will be ruined.

This short note can only give a small selection of these excellent plants. Their position in the greenhouse or conservatory for winter and early spring decoration is unassailable, but they are so easily grown that cultivators are inclined to become a little careless. Numbers of plants can be seen whose appearance would have been just a little improved if simple methods such as are described above were followed out. T. W. BRISCOE.

THE ALPINE LAWN

BY CLARENCE ELLIOTT.

THERE has sprung up among rock gardeners during recent years a distressing mania for indiscriminate massing. Gigantic slabs of aubrietia are planted, Dr. Mules after his kind and Fire King after his kind, each to each, in a studiously irregular sort of futuristic bedding out.

AN ALPINE LAWN IN SWITZERLAND POPULATED WITH THE HANDSOME AND GRACEFUL RANUNCULUS PYRENÆUS.

DOUGLASIA VITALIANA WITH ITS SMALL YELLOW FLOWERS AND PROSTRATE HABIT SHOULD BE GROWN IF SPACE PERMITS.

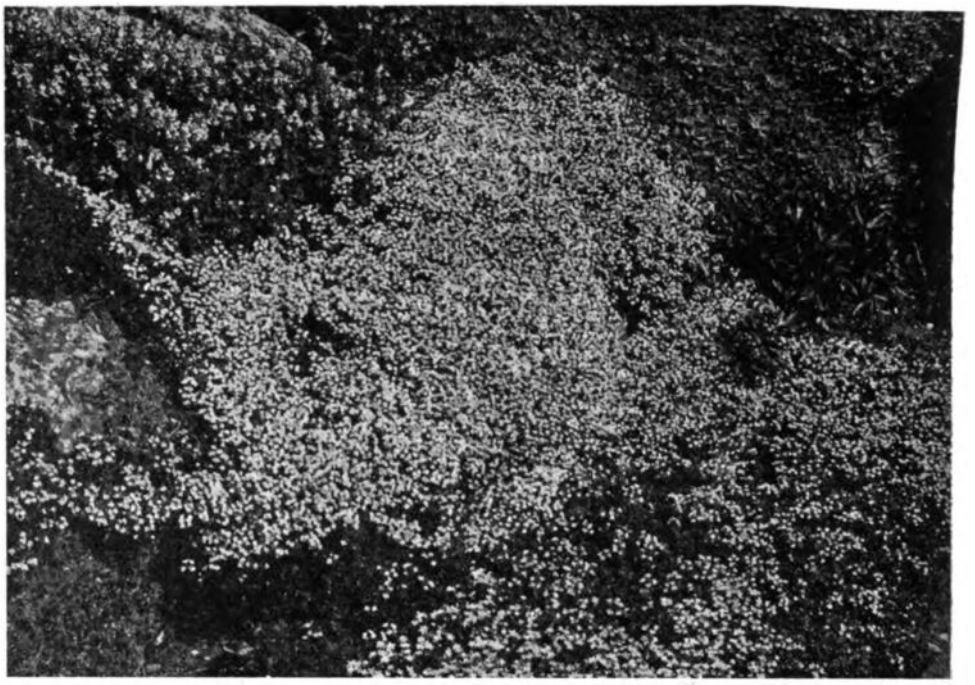
I admit that bold massing of colour can be very effective in the rock garden, and I confess that I often practise it myself. But one must guard against too rigidly shepherding one's plants. I once planted 16,000 Erica carneas in one fell swoop on a hillside adjoining a big rock garden that I was planting. But I broke up the mass by adding several dozen big specimens of Erica arborea and an under-planting of some thousands of Trillium grandiflorum.

There are some alpines which are best massed. Others should be planted as isolated specimens, while others, again, are essentially mixers. Gentiana acaulis I would always plant in unadulterated drifts, although in nature it grows in small but frequent tufts scattered through the turf. Erinacea pungens I would always plant as solitary specimens. So, too, the Kabschia saxifrages, S. Burseriana and the like. They are bad mixers. But in the general planting of the rock garden I have come more and more each year to lean towards mixing as a means of avoiding any appearance of jazz bedding out. I mix aubrietias, and I love to place mossy phloxes of different colours so that they will run into one another. Arenaria montana will tangle itself delightfully through a mass of Lithospermum prostratum, and if a streak of Heavenly Blue strays in as well so much the better. The only use for the albino Gentiana acaulis is to drop one casually in among a host of the blue type, to suggest the occasional albinos one comes across in the Alps. Or in planting thrifts you may make a pretty drift of the white Armeria maritima alba, another of the deep pink variety Laucheana, and yet a third of the deep crimson Vindictive. And then you label them. Good. But take a dozen Laucheana, five of Vindictive, three of alba and a dozen of the old common pale chalky pink one, mix well together and plant in an irregular undulating drift, and you will have some sort of a reminder of the way thrift grows on the sea coast, in endless and ever-fascinating variety of colour tone. Not only this, but you will have done away with the possibility of at least three labels in your rock garden. You cannot label a mixed batch such as this.

Five or six years ago I made a new experiment in mixing. I had an old stone sink about 3ft. long, 2ft. wide and 3ins. or 4ins. deep, and decided to make a tiny garden in it. As a development of my growing mania for mixing I collected together a great store of small turf-forming alpines. Among others were Gentiana verna, Arenaria verna, Primula farinosa, P. scotica, P. minima, Douglasia Vitaliana, Silene acaulis, Antennaria dioica, Azalea procumbens and so forth. All these and some others I planted, mixed and very close together, in my sink. And then one day, about a year later, a strange thing happened. I was looking at my sink garden and was reminded of the Alps. A common old stone kitchen sink rescued from a builder's yard is the last thing to which one would go to be reminded of the Alps. Yet I felt then as distinctly Alp-sick as one may feel home-sick. The feeling was so strong that I wondered why, and then realised that my little mixed garden—one corner of it especially—was an almost exact reproduction of the close-flowered lawns that

Digitized by Google

one finds everywhere in the high Alps. The plants had matted together. It *was* an alpine lawn, all except the fine grass, and that did not seem to matter. And I realised that I had happened on a great discovery—the problem of the alpine lawn. Always one had longed to grow the lawn alpines in lawn. The grass had always been the difficulty. Folk had experimented endlessly with various grasses, I had done so myself, but all to no purpose. Every grass that was tried grew rampant and thugged the alpines to death. But leave out the grass altogether, choose your plants with care, mix them, and they will themselves mat together and form a turf, and not only give a delicious sense of flowered alpine lawn, but many of them will be all the happier for the root association that the plan provides.



ONE OF THE MANY SMALL ROCK PLANTS, THYMUS SERPYLLUM, WHICH BY ITS TANGLED GROWTH RAPIDLY FORMS A DENSE MAT.

This method of making alpine lawns need not be confined to stone sinks, though a sink is an excellent thing to begin with and experiment in. You may just as well begin in a pocket of the rock garden. Let the soil be not too rich, and plant thick, even if you have to begin on a small scale. Besides the plants I have mentioned I would suggest also the following: Viola Bertoloni, V. gracilis Lady Crisp, V. heterophylla (if you can get it), Polygala calcarea, P. vulgaris, Myosotis rupicola, Bellium minutum (Little Mary), the single red daisy which is called Bellis sylvestris and isn't, Oxalis magellanica, Primula longiflora, Ranunculus pyrenæus, Raoulia glabra, Silene alpestris, Thymus Serpyllum minutum, and so on and so on. Labelling is, of course, out of the question. Tidy-minded gardeners may think this mixed lawn planting too wild and uncouth. Those who love the flower lawns of the Alps will find it couth, perfectly couth, and delightful.

THE ALPINE LAWN WOULD NOT BE COMPLETE WITHOUT ARENARIA PURPURASCENS.

AZALEA PROCUMBENS WILL SPRAWL OVER THE SLOPE AND WILL FORM ITS OWN TURF.

SUMMER SALADS

ALTHOUGH salads are much appreciated all the year round, they are in great demand during the summer months, when, next to luscious fruits, they form the most refreshing of foods. Of course, the plants should be home-grown and so due preparation of the various crops should be undertaken in good time in the garden.

BEETROOT.—The current year's crops are not available before the latter part of summer; the globe varieties being the first to mature for the salad bowl. It is during the late summer and early autumn that this root is most appreciated. The soil, for both the globe and long-rooted varieties, should be deeply broken up and, if poor, well enriched with rotted manure, several weeks prior to the time for seed sowing. There is nothing gained by sowing seed too soon, even in the southern counties. The first week in May will suit admirably; and from May 10th to 20th in more northern counties. With the aid of the garden fork loosen the surface soil and make it even finer with the rake. Draw out shallow drills 14ins. apart, sow the seed thinly, thin out the resultant seedlings gradually, finally leaving the best plants about 8ins. apart. Sparrows are fond of the young leaves and should be guarded against. Keep the Dutch hoe in use every week, to prevent the growth of weeds and hasten the swelling of the roots. Red Globe, Cheltenham Green Top, Dell's and Crimson are good varieties.

CELERY.—The white varieties are the most serviceable for summer salads. The plants grow quickly and are easily blanched. The seedlings, when quite tiny, should be transplanted nearly 2ins. apart, in boxes filled with a light, rich compost made moderately firm. The plants will grow steadily and satisfactorily in a frame at this season. The permanent shallow trench, or bed, should be prepared forthwith, the soil being rich and firm. Celery thrives in rotted manure, fine soil and soot, with a good sprinkling of wood ashes. Gradually harden the young plants and carefully transfer them to the trench late in May and early in June. Water regularly in dry weather and apply diluted liquid manure and clear soot water weekly when the plants are growing freely. Remove the basal side shoots, tie up the stalks loosely and wrap strips of brown paper round each plant to ensure blanching. A handful of coarse sand, ashes and soot, mixed, placed round the base of each specimen, will keep slugs away to a great extent. Solid White, Sandringham White and Sulham Prize Pink are very suitable.

CHERVIL.—A fine soil is essential for the successful raising of the seedlings. Given this attention any ordinary soil will do. Simply keep the seedlings free from weeds and thin out the same way as in the case of parsley. Sow, first, early in April and several times till the end of July.

CHICORY.—Although this is used during the winter months the roots must be grown in the summer. Ground prepared as for parsnips will do for chicory. Sow the seeds in shallow drills 14ins. apart and thin out the resultant seedlings to 9ins. apart. The object should be to grow very strong roots and crowns for lifting and forcing in the winter.

CORN SALAD.—The seeds should be sown in a rich soil about the third week in July, to form a supplementary crop to other salads; although, those cultivators who like to be able to gather leaves earlier may sow the first batch of seeds in April. Sow in drills 1ft. apart and thin out the young plants to 8ins. apart. Gather the leaves separately, the same way as when gathering spinach.

CRESS.—The best way is to set apart a portion of a north, or north-west border on which to raise plants in batches to succeed those raised under glass. The soil should be made very rich, levelled, watered and the thickly-sown seeds pressed lightly into the wet surface with a flat board. Sow seeds fortnightly.

CUCUMBER.—Undoubtedly, this is regarded as a very important salad whenever the fruits can be secured. The early ones are highly prized. It is rare, nowadays, to find a naturally bitter variety; the bitterness, when present, is, mostly, owing to cultural defect, a too cold temperature and over-long period of growth.

At the present time no doubt many readers of THE GARDEN will possess some young plants in 3in. pots—or larger—and bearing three or four rough leaves. Such plants should be transferred to beds of light compost on hot-beds in houses or frames, without delay. A summer temperature, atmospheric moisture, water and liquid manure at the roots, syringing and closing the structure with sunheat available after three o'clock in the afternoon, tying and stopping shoots at every joint beyond the show of fruits, all combine to ensure a plentiful supply of tender cucumbers.

In frames very similar treatment is required, but more care should be taken in the matters of watering, syringing and ventilation; the weather conditions will be a good guide when the cultivator is deciding what should be done. On the warmest days less moisture will be required and on cold nights the lights should be covered. All fruits should be cut when about three-parts grown. Improved Telegraph and Tender and True are reliable varieties.

Ridge cucumbers are very useful, but, instead of planting on the ridge in the usual way I favour planting on the sides of a 9in. deep trench formed on the ridge. The young plants are protected from cold winds and soon grow over and cover the whole ridge. Stockwood is a good bearer.

ENDIVE.—This is not a suitable salad plant for the early part of summer, but should be grown to be available from August onwards. A very common mistake is that of allowing the young seedlings to remain in an over-crowded state till they become long-leaved and weakly. The plants thrive in a rich soil and should not be planted closer than 9ins. apart. The first sowing will be timely if made in May, and the last ones in August. The Moss Curled is splendid for late summer, and the Round-leaved Batavian for the autumn and winter supply. This variety should not be planted closer than 1ft. apart.

LETTUCE is quite indispensable, and, like endive, should be well grown. There are many excellent varieties now obtainable, both Cos and Cabbage. It is not mere size of outside leaves that counts, but the size and number of inside ones perfectly blanched. Where naturally shallow soils obtain, the cultivator should double them by forming raised beds. Lettuces always thrive well on the ridges between celery trenches, because there is an extra depth of soil for them to root in. Where soils are deep and rich there should not be any difficulty experienced in growing fine specimens. The hotter and drier the weather, the more surface hoeing between the rows of plants should be the rule. All the Cos varieties blanch more satisfactorily when they are neatly tied up when the inside leaves are quite dry. It is better to sow a few seeds monthly from spring to September than to sow more seeds every three months. All transplanting should be done while the plants are small, the larger they are the greater the check to growth and the sooner they "bolt" to seed. Paris Green, Paris White and London White Cos; Early Paris Market, Commodore Nutt, All the Year Round, Continuity and Stansted Park are excellent varieties of Cos and Cabbage sorts respectively.

MUSTARD.—This should be treated similarly to cress.

ONION.—Salad onions should be small and tender, not large-bulbed, even in winter time. After the young surplus plants—the thinnings—are exhausted, seeds should be sown in drills, monthly, throughout the summer, and in frames and boxes in the autumn and winter. The onion in a salad bowl is not appreciated by every person and its judicious use may be necessary.

RADISH.—The radishes raised under glass in spring are, if well treated, tender. But when the cultivator attempts to grow really tender roots on a hot, dry border in the summer, his skill will be taxed. A north aspect, but with overhead shade, is desirable. A moderately rich soil, made firm is essential. The French Breakfast, the Olive-shaped and the Turnip-rooted are preferable to the Long-rooted sorts. The seeds should not be deeply covered, only just hidden from sight, and broadcast sowing is preferable to drilling, overcrowding should be avoided, regular supplies of water may be needed, but a point is gained if the soil is thoroughly soaked just before the seeds are sown. Frequent and small sowings are the most satisfactory.

SORREL.—This is highly appreciated by many persons in the salad mixture. Sow the seeds in well broken soil in shallow drills 12ins. apart and duly thin

Digitized by Google

out the seedlings to 12ins. asunder. The object should be to grow few plants possessing many succulent leaves, not tiny leaves on numerous plants.

TOMATO.—Fruits from plants grown under glass are available over a long period. But cultivators who are obliged to depend upon open-air plants should be sure that only strong specimens about 1ft. high are available for planting in well prepared ground in the warmest positions about June 10th. The tops of all outdoor grown plants should be pinched off before August 10th to ensure the retained crop of fruits ripening.

WATER CRESS.—Where there are clear water streams and shallows, young plants should be pinned down under stones at each side—not in the centre. Failing streams the cress may be grown in shallow trenches containing a rich, moist compost. The best aspect is one on the north side of a wall, or fence. Plant in May. GEORGE GARNER.

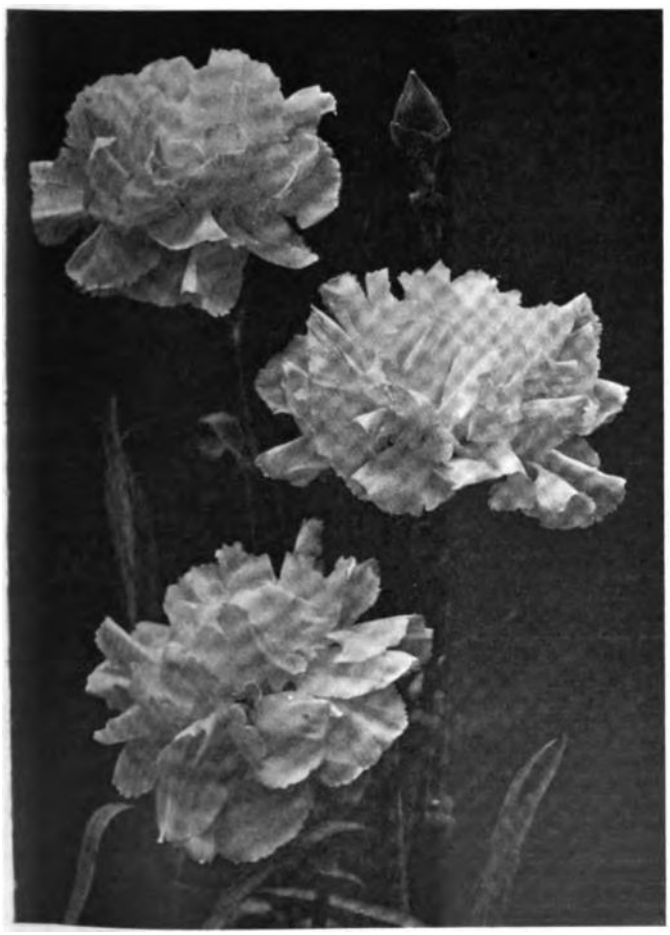
THE BRITISH CARNATION SOCIETY'S ANNUAL SHOW

WITH the help of some miscellaneous exhibits from the previous days' R.H.S. show, the British Carnation Society were able to fill the Royal Horticultural Society's Hall at Westminster on March 27th, the occasion of their annual show.

From the spectacular point of view, the chief interest in the show lay with the monster trade collections of magnificent blooms. Just inside the entrance Messrs. Allwood Bros. had an excellent exhibit and displayed delightful stands of such splendid sorts as Maine Sunshine, yellow; Chintz, mauve and claret fancy; Edward Allwood, brilliant scarlet; Laddie, pale salmon; Marion Wilson, yellow flaked with bronze; Topsy, crimson; Wivelsfield Apricot and Wivelsfield Claret among the true perpetuals. While of the larger and richly fragrant perpetual malmaisons, Atlantic, pink flushed; Jessie Allwood, rich yellow; Mrs. C. F. Raphael, cherry red; and Oceanic, shrimp pink, were equally desirable. Besides this large collection of superb blooms Messrs. Allwood Bros. made a fascinating grass bordered bed of their "Allwoodii" varieties on the floor.

On the right-hand side of the entrance Mr. C. Engelmann had a very large collection of excellent blooms, also arranged with admirable taste and skill. Among the newer varieties which Mr. Engelmann offers are Donald, a good crimson; Scarlet Iona; and Vera, rose pink. His others included Cheerful, cerise; Carola, crimson; Enchantress Supreme, light salmon pink; Happy Day, scarlet; Lady Northcliffe, salmon pink; Peerless, deep rose pink; Red Ensign; Saffron and White Delight.

ELDORA—A FANCY VARIETY, CLEAR WHITE, PENCILLED WITH ROSE PINK LINES. AWARD OF MERIT.



THE SHAPELY COMPACT BLOOMS OF TESS. A BEAUTIFUL PERPETUAL CARNATION. AWARD OF MERIT.

Chief among the many sorts well set out by Messrs. Stuart Low Co., was their beautiful White Pearl. Next came the salmon pink Eileen Low, with the more delicately coloured Hon. Nita Weir. Lady Inverforth, of old rose colouring; Reginald Cory, cerise crimson; and Susan Pam, rose cerise, are other outstanding novelties. Messrs. Keith Luxford and Co. displayed an attractive collection of the best sorts, including Aviator, scarlet; Baroness de Brienen and Iona, salmon pinks; Fanny, light pink with red stripes; General Joffre, orange scarlet; and Mrs. C. W. Ward, deep pink.

In the trade classes Mr. C. Engelmann was the principal winner of the first prizes with wholly admirable exhibits. His vases of a hundred and of fifty blooms each were magnificent efforts. His English-raised three varieties, winning first prize, were White Pearl; Nigger, crimson; and Cupid, pi-

Mr. W. H. Page showing the rose cerise coloured Edward Page was first with one vase of a British raised variety.

One exhibitor was also pre-eminent in the amateur classes, where Sir Randolf Baker, Ranston House, Blandford, won most of the first prizes with most praiseworthy blooms. Mr. R. Lan, Sheepwell House, Potter's Bar; Mrs. J. A. Otter, Queenswood, Ottershaw, and Mr. H. Clipstone, Melchet Court Gardens, Romsey, won first prizes in what was apparently the same division, while Mrs. Walter Hyde, Kempton Park, was consistently successful in her section.

The decorative classes did not bring out any novel or superlative style, though all the exhibits were fresh and pretty. The first prize for a dinner table decoration was awarded to Sir Randolf Baker, who used pink carnations, though the concensus of opinion seemed to be in favour of the second prize arrangement of an apricot yellow variety. Sir R. Baker was also first in the class for a decorative vase of not more than twenty-five blooms.

Sir Charles Nall-Cain, Brockett Hall, Hatfield, won the first prizes for a group of carnations in pots and for six plants, and in each instance exhibited plants which displayed first-class cultivation.

The "New Plants" table was filled with some interesting novelties, of which two received awards. In addition to these, Chintz (Messrs. Allwood's fascinating mauve and claret fancy carnation), Sharston Gem (a bright purple flower, though a trifle thin in habit, shown by Mr. C. G. Hill) and Sir Philip Sassoon (a fine deep crimson maroon, raised by Messrs. Stuart Low Co.) were all well worthy of attention.

AWARDS OF MERIT.

ELDORA.—This is a very beautiful white ground fancy carnation. The ground is a particularly clear white on which is pencilled well defined, narrow rose pink lines. The well formed and fragrant blooms are freely produced. Award of merit. Shown by Messrs. Allwood Bros.

TESS.—The shapely, compact blooms of this carnation are of good size, milky white and very fragrant. The edges of the outer petals are regularly serrated. There were plenty of flowering stems, while the foliage was sturdy and healthy. Award of merit. Shown by Mr. George West.

CORRESPONDENCE

ALPINES FROM THE PASS OF MONT CENIS.

IN the preceding discussion on the above subject it has been satisfactorily established that there is on the one hand a Campanula linifolia, which is a high alpine form of Campanula rotundifolia, and, on the other hand, a totally different species which is the C. linifolia of Lamarck as described by Coste and Flahaut. Who, however, would be so bold as to define the differences between C. Scheuchzeri and C. linifolia of the former persuasion? I would therefore suggest with the humility due from a tyro that the name C. linifolia should in the interests of clearness be retained for that Eastern form described under that name by Mr. Thompson and which has marked peculiarities, and that the name C. Scheuchzeri be considered sufficient for the other high alpine forms of C. rotundifolia referred to by Mr. Lofthouse and Mr. Elliott. This I believe to be in accordance with the nomenclature of M. Correvon. The other linifolia of Coste and Flahaut appears to take its name from the French "à feuilles de lin" (flax-leaved) and is described by Flahaut as with furrowed stems crowded with sessile linear-lanceolate leaves, terminating in a spike of up to eight short bells, and as being found in the Vosges, Jura, Alpes de France, Auvergne, Cévennes and Pyrenees. It grows taller and belongs to a lower altitude than any of the high forms of rotundifolia. It suggests a hybrid between CC. rotundifolia and rhomboidalis.

As Mr. Thompson states that Lychnis alpina is very uncommon, may I give the Val d'Isère district—on the way up to the Col de l'Iseran and again above Prariond—as a place where it may be seen, though not in abundance.

Campanula spicata was much finer—indeed, a most handsome plant—at Val d'Isère by the side of the valley path between le Fornet and le Malpas than on the Mont Cenis. The same was true of Hugueninia tanacetifolia, which grows in the Mont Cenis potholes, but not so freely as at Val d'Isère (at much the same height), where foliage and yellow heads were equally handsome and clothed upstanding rocks with waving picturesqueness.

As Ranunculus glacialis is reputed, unlike other high alpines, not to be carried down to levels below its normal altitude, it is of interest to note that I found it just below the west side of the Fort de Varisello on the steep bank by the side of the military road at an altitude which could not have exceeded 6,500ft. There was only one plant of it. I also came across a large and densely crowded area of R. glacialis, growing and flowering with the exuberance of marsh marigolds, about half way between the Lac de Combal and the lower Chalets de l'Allée Blanche near Courmayeno at an altitude again below 6,500ft. The explanation is, I think, in this latter case, clear: the Val de l'Allée Blanche is, as its name implies, the collecting ground of the melting snow and ice of half a dozen glaciers which are in close proximity, and the climatic conditions are akin to those normally appertaining to higher altitudes. To anticipate possible criticism, this was definitely *not* Ranunculus Seguieri. In the same valley at the same time were found Thlaspi rotundifolium, Armeria alpina and Ranunculus alpestris, a trio belonging normally to higher altitudes. The presence of R. alpestris here may interest Mr. Thompson, as in "Alpine Plants of Europe" he remarks on the fact that he failed to find a single specimen in Piedmont and other places west of Switzerland. The trio mentioned are mainly plants of the calcareous formations, yet along the entire length of the valley from the Col de la Seigne in the west to the Col Ferret in the east there is nothing to be seen but huge granite boulders. Near both Cols, Anemone sulphurea is in abundance.

To come back to the Mont Cenis, Saxifraga valdensis, whose normal habitat is, I understand, south of this, is to be found within two to three hours' and a pure white Silene acaulis within half an hour's, walk from the Hotel de la Poste. Not far from the white silene is a clump of that most beautiful primula which is, I believe, a natural hybrid between P. pedemontana and P. viscosa, much finer than either, and is, I understand, known as P. Bowlesi.—E. ENEVER TODD.

THE PRUNING OF PRUNUS TRILOBA.

THE illustration of this beautiful flowering shrub, accompanying Mr. R. Irwin Lynch's note in the issue of March 29th, page 212, depicts better than any words of mine could explain the value of pruning. For something like forty years this specimen was freely pruned annually after flowering until attacked by silver leaf. Mr. Lynch suggests annual pruning results in "stubby and comparatively weak shoots 8ins. or 9ins. long," but this plant, for the pruning of which I was responsible for a number of years, made vigorous young growths each season up to 2ft. or more in length, covered with flowers from base to apex as the illustration shows. For bushes in the open I agree with Mr. Lynch when he says hard pruning "is quite contrary to Nature," but Nature does not grow shrubs against a wall. Experience leads me to the conclusion that if these vigorous young shoots are left unpruned for a year or two as suggested the specimens in a few years grow away from the wall and get out of hand.—A. O.

THE SPURGE LAUREL.

SIR HERBERT MAXWELL makes a mistake in describing the greenish flowers of the spurge laurel, Daphne Laureola (page 212), as "scentless." It is true that they are almost scentless during the day and quite so in strong sunshine; but during the night, and especially during the twilight, they are scented with a peculiarly sweet though not sickly perfume, like the night-scented stocks (Matthiola bicornis and M. tristis).

The writer has grown this daphne for many years for the pleasing odour of its flowers, and, to be certain that it had not lost this peculiarity in the way that ordinary "musk" has, sallied forth at 9 p.m., immediately on reading Sir Herbert Maxwell's note, to find that the scent was quite as strong and sweet as in the days of his youth, when it grew as a shrub fifty years old and 5ft. across, scenting the twilight air for yards around in his father's garden.

Although he has often thought that this shrub might be fertilised by night-flying moths, he can confirm the statement that no insect has been found to visit the inflorescence. It sets its black berries freely, and is probably self-fertilising.—R. J. S.

HERBACEOUS BORDERS.

ALL gardeners know the difficulty of keeping herbaceous borders bright throughout the summer, and I think one of the reasons for the difficulty is to be found in the use of unsuitable plants. There are plants which take up considerable space and only last in flower a short time. In an interesting article in THE GARDEN a few weeks ago astonishment was expressed that so little use was made of peonies. A good-sized peony plant takes up the space of a circle about a yard in diameter and lasts in flower about a fortnight, which means that your border has the space it occupies devoid of bright colour for the rest of the season. There are other plants which have the same drawback. The non-bulbous iris is one of them. The common day lily is another and the lupin another. I do not wish to contend that none of these flowers should be grown, but only that they should

Digitized by Google

have a place found for them which is not the herbaceous border, and a small garden will have to do without them. I doubt if a successful border can be made and remain bright throughout the summer without the use of annuals, for with them blank spaces can be filled, especially if a little nursery for them is kept, from which they can be shifted to where they are needed in the border. My experience leads me to think that for most summers—and summers vary greatly—it is easier to have a bright border on the north rather than on the south or west side of a wall. Also that you must not try to grow spring or autumn flowers in your summer border, and, of course, winter flowers are out of the question.—THACKERAY TURNER.

THE KING ALFRED DAFFODIL.

I HAVE been interested in the notes appearing recently in THE GARDEN about this daffodil. I have planted a few bulbs during the last three seasons in various borders, as the soil differs. The flowers of those planted in autumn, 1921, in rather light soil were last year not up to the first season of flowering and do not seem to be any more promising this spring, but the foliage and buds of those planted in autumn, 1922, appear to be as good as last season. These were planted in a fairly heavy soil with a little sand added. All the soil here is rather chalky. I mix in a little bonemeal at planting-time, well away from the bulb. I have used hop manure, but do not find it altogether satisfactory.—H. HANCHET, *Purley*.

LONICERA NITIDA.

IN the days before male attire had assumed the sub-fusc hues which now prevail, some philosopher remarked that "if there were no difference of opinion there would be no fancy waistcoats." The praise bestowed on Lonicera nitida (page 198) brought this saying to my mind, for I have formed a very inferior estimate of the merits of this plant. It flourished here for several years. The specific name "nitida" aptly describes the neat foliage, but the flowers are well-nigh invisible. They ought to be followed by very pretty translucent violet berries; but in some seasons no fruit was formed, and even when they did ripen they were very few and far between. Perhaps our climate is at fault; but, whereas the exceeding multitude of beautiful exotics now at our disposal renders discreet selection essential for every amateur, we decided that the space filled by Lonicera nitida might be given a worthier tenant; wherefore out it went to the rubbish heap, together with a couple of bushes 8ft. high of Viburnum rhytidophyllum, a poor representative of a very distinguished family.

We are told this honeysuckle makes a good hedge plant. No doubt it does; but if I wanted an evergreen hedge and was not content with holly, which for that purpose moved John Evelyn to rhapsody, or with Monterey cypress, which is matchless in verdure near the sea, I would plant, say, Osmanthus Delavayi, one of the choicest shrubs that has come to us from China, loading its sprays every April with fragrant white blossoms, and as easily propagated as the common—too common—privet.—HERBERT MAXWELL, *Monreith*.

THE DELPHINIUM.

I WAS much interested in Mr. Engleheart's letter in your issue of March 29th on the delphinium. My soil is very light, and I use no water to them, but they do well, running up 5ft and 6ft. With him, I think there are too many nondescript colours now. I was looking at several collections in different shows at Chelsea and Regent's Park, and in none was there a good clear blue; in fact, blue was conspicuous by its absence. Slugs do create havoc with most of the plants, but a fresh enemy attacked mine—a rat cleared a boxful of seedlings in my greenhouse, quite a new departure I should think.—F. W. HARRIS.

ANEMONES AND HEPATICAS.

I TRUST it will not be considered sacrilege if we consider one point in the late Maurice Hewlett's delightful and beautifully illustrated article on Anemones (March 22nd, page 188.) He modestly suggested that "the *feeling* of the two flowers [anemone and hepatica] is distinct and separable. . . . The anemone is gregarious, the hepatica solitary; the anemone is a spring flower, the hepatica a winter flower." Now, all this is perfectly true in so far as the plants are concerned in English gardens, but Mr. Hewlett cannot have had the joy of seeing the splendour of A. hepatica growing wild in its tens of thousands from March to May in Switzerland, or in April and May in mixed woods in the Pyrenees. It is only in gardens that we are accustomed to see solitary clumps of hepatica (and usually the red ones) which should not be moved, as Mr. Hewlett so forcibly pointed out. Can he have seen Flemwell's delicate and beautiful picture of hepatica in the woods at Bex, in the Rhone valley, in April; or have read on page 6 of that writer's "Alpine Flowers and Gardens": "As the snow recedes, the brown bed of the pine forests is decked with myriads of hepatica; their thick clusters of mauve-blue blossoms, relieved here and there by the rarer forms of white and rose . . . ; creating a veritable laughing fairyland"? It is chiefly in March and April that the snow recedes from those comparatively low levels, when few English visitors are in Switzerland; and it is in the months of April and May, as Flemwell says, "there is in progress a rapid and delightful transformation which it were a thousand pities to miss." In Switzerland the hepatica blossoms about the same time as the wood anemone (A. nemorosa), A. Pulsatilla and the scarcer A. montana and yellow ranunculoides. A. vernalis pushes its shaggy buds through the melting snow at higher elevations a month later. The hepatica is only one of many Continental plants which invariably blossom earlier in English gardens than in their native haunts, though I have seen A. hepatica, *e.g.*, at the end of June at 7,000ft. in the Alps, and as late as May in hills above the Mediterranean. Something bearing on the curious anomalies of flowering in different latitudes appeared in THE GARDEN, March–April, 1922. The late Mr. Hewlett did not call to mind more than one of the poets having sung about the windflowers. When wanted such things are difficult to recollect, but, naturally, there are others, and among French writers and poets I have a vague idea that M. Correvon is one. Certainly in these columns a few years ago some very charming verses by Alfred Hayes, M.A., on "Hepatica" were quoted, but though sent by me I cannot find the reference.—H. S. THOMPSON.

LABELS FOR ALPINES.

THE article on Labels by Mr. Gerald Hillier in THE GARDEN of March 29th presents a point of view both in letterpress and illustrations with which I entirely disagree, at least in respect of private rock gardens. Mr. Hillier advocates prominently legible labels to prevent inexpert friends from scrambling over the rocks, and he illustrates part of a rock garden which is disfigured with a perfect forest of labels, amid which a closer examination reveals what is apparently about one plant to three labels. Such a method may be a grim necessity for public rock gardens, but for private gardens it is surely indefensible, for, while it provides information and permanence, it entirely fails to fulfil the third and indispensable desideratum of inconspicuousness. To attain all three desiderata there is, I think, no method except numbered labels. In my own rock garden I use these exclusively. The numbers are stamped at the top of narrow 5in. zinc labels, which are then buried up to the number behind the plants, and are therefore almost invisible. For alpines I have some 800 of these with plain numbers; for small bulbs I have some 300 with the letter B above the number. A better way would possibly be to use square-topped labels with just the sharp corners taken off for alpines, and round-topped labels for bulbs. I make my own labels from thinnish sheet zinc. The numbering is easily and quickly done, requiring only a block of wood topped with lead, a hammer, and a set of number stamps from 0 to 9, which can be bought for a few pence. This plan, of course, necessitates keeping a book (or books), registering the numbers and occupants, but this in itself adds an interest which far outweighs the little trouble it entails. I would claim that this system alone fulfils the three desiderata of information, permanence and inconspicuousness. It is cheap, and doubly cheap because the numbered labels, unlike those with written or stamped names, are interchangeable. You may in 1924 proudly enter under the number 13 (*absit omen!*) the august name of Eritrichium nanum; in 1925 you may, I had almost said you will, erase that name and substitute Androsace imbricata; in 1926—but why pursue the gruesome story. Humble people like myself, who are neither super-experts nor irrepressible optimists will wisely keep certain numbers (not 13!) with large spaces opposite them for recurring erasions and additions!

There remains the difficulty of circumventing the inexpert friend who may wish to tear your heart-strings by scrambling over your rocks to find out the name of some distant treasure. Trusted expert friends—and there are an increasing number of these of both sexes—may be armed with a numbered record book and turned loose; but the untrusted, and above all the gushing beginner, on whose "rockery" at home there is, as you are proudly told, a whole plant of Gentiana verna in flower (bought in bud from a nursery!)—these must be sternly warned off except under the owner's personal guidance. It may be, it is, a nuisance—for the people you can trust are usually the very people to whom it is a real joy to show your treasures—but it is the only way, and oh! it is worth it to avoid what to me are the horrible drawbacks of the method advocated by Mr. Hillier.—E. S. LYTTEL.

[We do not agree with the Rev. Lyttel's argument. (1) Labels such as he suggests necessitate a large number of paths if the garden is not to be walked on continually. (2) It means that a note-book has constantly to be carried round the garden. (3) In wet weather the disadvantages are obvious. (4) It is sufficiently difficult to name plants correctly without doubling the chances of wrong nomenclature by reason of two lists, one with numbers, the other with names.—ED.]

TREATMENT OF RHODODENDRON SEEDLINGS.

IN the issue of THE GARDEN dated March 29th, in my article "Treatment of Rhododendron Seedlings," Column 2 and the 43rd line, an unfortunate error has occurred. This should read: "The rhododendrons in this group are those Mr. Forrest describes as found growing on limestone. This was proved when they were germinated in a compost where peat was used;"—L. B. STEWART.

[It is regretted that this typographical error in Mr. Stewart's article occurred. —ED.]

NOTES FROM CONTRIBUTORS

BUD SPORTS OF APPLES.

THESE bud sports often originate and pass unnoticed—in fact, two originated on trees under my charge but did not appeal to me at the time as being worth propagating. The one bud sport was a crimson King of the Pippins, the other was an all-russet fruit of Ribston Pippin. The Scarlet Golden Pippin appeared as a bud sport on an old tree of the Golden Pippin in 1846 at Gourdie Hill in the Carse of Gowrie, Perthshire, then the property of Mr. Robert Matthew, and was perceived by the late Dr. Hogg. At the time of his visit it was a branch thickly set with fruit-bearing spurs. During the season some specimens were sent to Dr. Hogg, who at once pronounced his liking for the apple and advised its propagation. The only tree of Scarlet or Crimson Golden Pippin is in a garden a few miles from Gloucester, this particular tree being worked from an old tree found in a derelict cottage garden on the estate. Mr. Harris, Bullingham, near Ross-on-Wye, has secured a bud sport from Cox's Orange Pippin which should prove serviceable for private, show and commercial purposes, as it will undoubtedly supply a "want" in every land and clime where the bonny apple grows. This sport was noticed on the south aspect of a tree worked on the paradise stock, the fruits being of a beautiful colour of intense crimson, and when sufficiently propagated will prove a decided acquisition. I understand the new variety is really a stronger grower than the original, which will surely prove advantageous, as Cox's Orange Pippin is of slender growth and habit. Another great point in its favour is its free-cropping propensities. Therefore, taking its character in general, it ought to make its mark, as highly coloured fruits of Cox's Orange Pippin always command a readier sale than those devoid of colour. I have an idea that this crimson variety would prove its character more definitely if worked on the free stock, although any lias strata would no doubt produce coloration on free, crab or paradise stock. This remark refers to apple-growing counties, as Hereford, Kent, Devon or Worcestershire. — GEO. LOVELOCK.

BUDDLEIA FARRERI.

I enclose a photograph of a plant of Buddleia Farreri which is flowering here. Being so recent an introduction it cannot be widely distributed, and it does not seem to flower easily. I obtained my plant from the late Mr. Farrer's nursery when the plants were being dispersed. It was planted outside against the south wall of my alpine house, and was badly cut back by frost each winter. After the first winter it was very late in starting and I feared it had died. The following summer it made stronger growth, but as there was no sign of it flowering, I had it lifted and potted up. It stood outside for some weeks with only a wall and the overhead shelter of a beech, and while in that position 20° Fahr. of frost was recorded on the screened thermometer. The house it was put into was used for growing chrysanthemums, and no water was given to the plant until it was well into growth. The first indication of flowering was seen in buds on the old wood, but as new shoots were put out they were seen to be carrying flowerbuds as well, and you can see from the photograph that there are flowers from both old and new wood. Owing to the treatment it had received the plant lost nearly the whole of its leaves, so the blooms developed very slowly to begin with, but latterly it has come on better, and the photograph was taken a fortnight after the first trace of colour was seen on an unopened bud. My plant is between 5ft. and 6ft. high. I hardly think it can be in character, as the flowers are a pale shade of mauve, while Farrer in his book, "The Eaves of the World," leads one to expect the bloom to be more nearly blue. The plant has thong-like roots, which agree with the situation in which it was found, stony ground in a dry, hot valley. It is evidently more suited for a warmer climate than mine is, and I shall be interested to know of any other grower who has succeeded in flowering it and under what conditions.—WILLIAM LOW, *Kincardineshire*.

A REMARKABLE PARASITE ON SUGAR CANE,
Note the leafless character and the hooded corolla tubes.

BUDDLEIA FARRERI, A RECENT INTRODUCTION FROM CHINA, WITH MAUVE TO BLUE FLOWERS.

A REMARKABLE PARASITIC PLANT.

ÆGINETIA INDICA is a very remarkable parasitic plant now flowering in the Victoria House at Kew. Like other members of the broom-rape family (Orobanchaceæ), it is a leafless plant which forms a large tuberous rootstock. Seeds received at Kew last autumn were immediately sown on the surface soil of a young plant of sugar-cane, the selected host plant. About a month ago flower-scapes began to appear, but on account of the exceptionally dull weather they were very slow in developing. The solitary flowers are borne on beautifully mottled, erect scapes, which spring directly from the swollen tuber to a height of 6ins. to 9ins. The corolla tube is hooded, about 1½ins. long, light purple in colour on the outside and dark purple within. This plant is a native of the East Indies, where it grows on the roots of tropical grasses.—T. W. T.

THE CHELONES.

THOSE who are on the look-out for a vigorous-growing and distinctive border plant of handsome appearance and possessing showy flowers should not pass by the Chelones Lyoni and obliqua. The former is the taller grower and rises to a height of 4ft., while it is distinguished by the slight hairiness of the leaves. The flowers, which appear in August and September, are of a fine purple colour and borne in dense terminal spikes. C. obliqua is a foot shorter, with perfectly smooth leaves and large purple flowers in similar spikes. Both are moisture-loving plants, the latter especially so, and it will be found to do exceptionally well on the margin of the bog garden.—CROYDON.

RAISING CACTI FROM SEED.

THE majority of species yield abundant supplies of seed, but on account of their unfavourable surroundings as a rule only a very few of these germinate and attain maturity. If, however, care is taken to save and sow these seeds under proper conditions, a large stock of plants can soon be obtained. Amateurs sometimes add manure to the compost in which the seeds are to be sown, but this is a mistake, as the manure tends to hold moisture and is often responsible for introducing germs of fungi, which are apt to cause decay. The seeds of some cacti are slow in germinating, and it is therefore a good plan to sterilise the pots so as to safeguard against algæ covering the surface of the soil with their slimy growth before germination has taken place.

Although ordinary seed pans and pots are suitable for sowing the majority of seeds, it is often found in the case of cacti that the drainage hole at the bottom of the pot or pan is far too small, and this should nearly always be enlarged. A plan often adopted in America is to cover the seeds after sowing with a very fine layer of soil and then on the top of this again to spread about a quarter of an inch of fine gravel. This gravel prevents the soil from becoming dry and also checks the growth of any green algæ over the surface of the soil. The seedlings will easily force their way through the gravel and the fine roots will benefit by this extra protection. Great care will be needed in watering and a can fitted with a very fine rose should be used.

The best time for sowing is during the months of March, April or May, as if sown later losses are often experienced during the first winter. The seeds of cacti are mostly very small. It is best to use shallow pans 3ins. in depth and about 5ins. in diameter. The pans should be filled to a depth of 1in. with crocks and the other two-thirds should be filled with a mixture of soil consisting of peat, sand and leaf-mould. The surface of the soil should be made perfectly level, and it is a good plan to use a flat piece of wood for this purpose. The seeds should then be sown and barely covered with the same mixture of soil which has been sifted very finely, and the pans should then be watered gently with a can fitted with a very fine rose.

The pans should, if possible, be placed in a frame with a temperature of about 60°, and this should be shaded with thin canvas to protect against bright sunshine. It will probably be necessary to water gently every day to prevent any danger of their becoming dry. Amateurs should endeavour to keep the seed pans in an even temperature where the same state of moistness is maintained all the time. Although many varieties germinate within a few days, it will be found that others are much slower, and sometimes months may elapse before the young seedlings appear. The quickest species in germination are the echinocacti and the mamillarias. The cereus and pilocereus sections, as well as the opuntias, require a longer period before germination takes place.

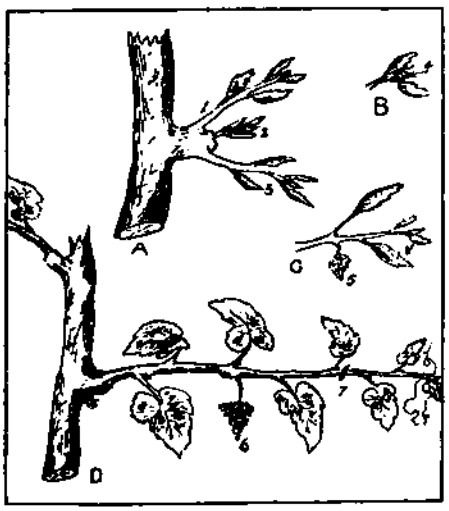
A month after the seedlings have germinated they may be pricked out into other pans, and when lifting them a small pointed stick will be found of very great assistance. The new pans may be filled with a similar compost to that used for sowing purposes, and if the plants are inserted very shallowly in the soil and kept carefully watered they will soon be strong enough to stand the winter.

They should be placed in a light sunny position in a greenhouse or warm sitting-room and watered once a week with lukewarm water.

The raising of cacti from seed is a fascinating hobby, as the young plants will be found to exhibit many interesting and varying stages of growth. The hundreds of different species include varieties some of which are prickly while others are quite smooth, or yet again covered with hairs and spines of different colours. The blossoms are often very beautiful both in formation and colour, and once the young seedlings are established the subsequent cultivation is simple.—R. W. ASCROFT.

GRAPE GROWING.

MANY grape vines are grown in cool or slightly heated greenhouses. The sun-heat has a beneficial influence on vines in all kinds of structures, but it is especially valuable in unheated ones. Owing to the prolonged spell of cold winds, vines in cool houses are later than usual in "breaking" this year. It is well that they are, as the night temperatures have been much too low for the welfare of new shoots. But as vines usually grow strongly after a good rest, cultivators should not be worrying on account of a late start.



ILLUSTRATED HINTS IN VINE CULTURE.

If vines occupy a house to the exclusion of other kinds of plants, there is no necessity for ventilation until the new shoots are quite 2ins. long. On very fine days the floor should be damped early in the morning, but not in the afternoon. Also it will be beneficial if the rods are syringed with tepid water about eight o'clock in the morning. Of course, more syringing, damping, etc., will be needed in the case of normally heated vineries.

Healthy vines generally bear several young shoots on each spur, as shown at Fig. A. The best-placed and strongest shoot should be retained and the others removed when the embryo bunches can be clearly seen. The top shoot, No. 1, is the best, Nos. 2 and 3 being rubbed out. Even at this early stage of growth the inexperienced cultivator can see the embryo fruit, the experienced vine grower will see the tiny bunch at a much earlier stage.

The embryo bunch of grapes is shown at No. 4, Fig. B. It is rose-flushed in such varieties as Black Hamburgh and Alicante, but almost the colour of the leaf in the case of Gros Colmar. The bunches of Muscat of Alexandria are very deeply tinted with rosy pink.

No. 5, Fig. C, shows the bunch developing, and expert cultivators would pinch out the point of the shoot at this stage. The amateur, however, may wait a little longer till the bunch is at the flowering stage shown at No. 6, Fig. D; then the shoot is to be pinched off at No. 7; or, if there is plenty of roof space to fill, the shoots should be stopped beyond the third leaf from the bunch.

Young shoots, naturally, grow straight up towards the glass, and they should be very gradually (by stages) brought to the wire level, the final tying being done when the vines are flowering. G. G.

THE SUNDEWS.

THESE are small-growing but extremely interesting plants, and are known under the name of droseras or insectivorous plants. They are native of various parts of the world, and the most common British representative, D. rotundifolia, is found in bogs and damp places, often where sphagnum moss abounds, but they do remarkably well if grown in a cool greenhouse. The Australian species, however, are among the finest in the genus, and they include D. binata, occasionally referred to as D. dichotoma, a fine plant with long spikes of pure white flowers. D. spathulata is another desirable plant of a close compact habit. When grown in full sunshine the leaves assume a reddish tint, when the plant is most attractive. The North American D. filiformis is also a beautiful species, and the same remark applies to D. capensis, which is a native of the Cape of Good Hope. Most of them flower during the summer months, but their chief beauty is in the leaves, which are covered with glandular hairs appearing to be tipped with dew, hence the popular name sundews. Droseras are of easy culture, and they require cool treatment throughout the year. Pans which are well provided with drainage material are the most suitable receptacles, and, as a rule, should be 6ins. or 8ins. in diameter. The repotting is done in the spring just before growth begins, and several crowns are placed in each, slightly raising the soil in the centre so as to form a compact specimen. The compost consists of live sphagnum moss and a small portion of peat with a little silver sand added. It is cut up fairly fine, and the soil is made firm around the roots. Plenty of rainwater is required during the growing period, and the surroundings are kept moist by spraying between the pans and sprinkling water on the floors. The plants enjoy full sunlight and ample ventilation when the weather is hot. Droseras can be increased by division, seeds and root cuttings, and the two latter methods are usually chosen. Seeds are sown as soon as ripe on a pan of sphagnum moss and peat, but it is advisable to remove the large heads of the former or they will grow and choke the seedlings. To obtain plants from root cuttings only roots from strong specimens should be selected, and these are cut into pieces an inch or so in length. They are placed on pans containing the mixture quoted above, and just covered with a thin layer of sandy peat. They are then arranged in a close propagating frame and, in a few weeks, growth will be visible. When sufficiently advanced they are potted off and gradually inured to cooler surroundings.—T. W. B.

IMPERIAL BOTANICAL CONFERENCE

Chairman of Executive Committee—SIR DAVID PRAIN, F.R.S.

THE Imperial Botanical Conference will be held at the Imperial College of Science and Technology, by kind permission of the Governing Body, from July 7th-16th. The subscription for attending the Conference is £1. Those intending to be present are requested to notify the Secretary (Mr F. T. Brooks, 31, Tenison Avenue, Cambridge), as soon as possible. The issue of special tickets for students is under consideration. There will be accommodation at the Conference for exhibits of botanical interest.

PRELIMINARY PROGRAMME

I.—SYSTEMATIC BOTANY AND ECOLOGY.

1. THE BEST MEANS OF PROMOTING A COMPLETE BOTANICAL SURVEY OF THE DIFFERENT PARTS OF THE EMPIRE.—Discussion to be opened by Dr. A. W. Hill, F.R.S., followed by papers by Dr. I. B. Pole Evans, C.M.G., Lieutenant-Colonel A. T. Gage, I.M.S., and Mr. J. S. Gamble, F.R.S.

2. CORRELATION OF TAXONOMIC WORK IN THE DOMINIONS AND COLONIES WITH WORK AT HOME.—Discussion to be opened by Mr. J. Burtt Davy, followed by papers by Dr. A. B. Rendle, F.R.S., Professor W. Wright Smith, and Professor W. G. Craib.

3. VEGETATION SURVEY IN DIFFERENT PARTS OF THE EMPIRE, AND TRAINING IN FIELD ECOLOGY.—Mr. A. G. Tansley, F.R.S., will introduce the discussion by briefly summarising the accounts of work already done. This will be followed by contributions from the following: Dr. O. Stapf, F.R.S.; Professor Troup; Professor J. W. Bews; Mr. R. S. Hole, C.I.E.; Dr. T. F. Chipp; Professor F. J. Lewis; Dr. L. Cockayne, F.R.S.

II.—GENETICS.

1. THE ECONOMIC POSSIBILITIES OF PLANT BREEDING.—Discussion to be opened by Professor R. H. Biffen, F.R.S., followed by Mr. F. L. Engledow, Dr. R. N. Salaman, Mr. F. Parnell, Mr. M. A. Bailey, and Mr. J. M. F. Drummond.

2. THE VALUE OF SELECTION WORK IN THE IMPROVEMENT OF CROP PLANTS.—Discussion to be opened by Professor J. Percival, followed by Professor R. G. Stapledon, Dr. W. L. Balls, F.R.S., and Mr. G. O. Searle.

III.—PLANT PHYSIOLOGY.

1. COLD STORAGE OF APPLES: AN ECONOMIC BIOLOGICAL PROBLEM.—For some time a comprehensive investigation of the problems of fruit storage has been in progress at Cambridge and London, organised by the Food Investigation Board of the Department of Scientific and Industrial Research.

2. CROP PHYSIOLOGY: MODERN METHODS OF ATTACK.—It is hoped that part will be taken in the discussion by Sir John Russell, F.R.S., Professor V. H. Blackman, F.R.S., Dr. W. L. Balls, F.R.S., Mr. R. A. Fisher, Mr. G. E. Briggs, and others.

IV.—PLANT PATHOLOGY.

1. OBSCURE PLANT DISEASES OF WIDESPREAD OCCURRENCE.—(*a*) Sugar-cane mosaic: Discussion to be opened by Mr. S. F. Ashby, followed by Mr. H. H. Storey. (*b*) Bud-rot of coconut and other palms: Discussion to be opened by Dr. E. J. Butler, C.I.E., followed by Mr. A. Sharples, Mr. S. F. Ashby and Mr. W. Nowell. (*c*) Brown-bast of rubber trees: Mr. A. Sharples and Dr. A. S. Horne.

2. THE RELATION OF PLANT PATHOLOGY TO GENETICS.—Discussion to be opened by Mr. F. T. Brooks, followed by Dr. R. N. Salaman, Dr. W. B. Brierley and Dr. W. F. Bewley.

3. THE RELATION OF FOREST PATHOLOGY TO SILVICULTURE.—Discussion to be opened by Dr. W. Borthwick, followed by Mr. W. E. Hiley, Dr. Malcolm Wilson, and others.

V.—EDUCATION AND RESEARCH.

1.—The possibility of promoting an interchange of staff and of post-graduate students between the Overseas and Home Universities and Research Institutions.

2. The desirability of providing further facilities for botanical research in the tropics and Dominions.

The discussion on these topics will be opened by Professor J. B. Farmer, F.R.S.

VI.—MISCELLANEOUS.

1. WOOD TECHNOLOGY.—Professor P. Groom will open a discussion on "Fungal Attacks on Timber." Professor V. H. Blackman, F.R.S., Dr. E. J. Butler, Dr. W. Borthwick, Dr. W. Brown, and others will take part in the discussion.

2. NOMENCLATURE.—A sub-committee has been considering the "Rules of Nomenclature," and an opportunity will be given to discuss its report.

3. LECTURES (illustrated by lantern slides).—Professor A. C. Seward, F.R.S., "Records of Ancient Plants within the Empire: what we know and what we need."

Mr. F. A. Stockdale, "The Peradeniya Botanic Garden."

EXCURSIONS.

The following excursions are being arranged:

Wednesday afternoon (July 9th). Royal Horticultural Society's Garden, Wisley.

Saturday afternoon (July 12th). John Innes Horticultural Institution, Merton.

Saturday afternoon (July 12th)—Monday (July 14th). Blakeney Point, Norfolk. (Conducted by Professor F. W. Oliver, F.R.S.)

Monday (July 14th). Rothamsted Experimental Station.

Tuesday (July 15th). Royal Botanic Gardens, Kew.

Wednesday (July 16th). Cambridge (this excursion may be limited to overseas botanists).

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

The Treatment of Convolvulus Soldanella (E. S.).—This variety is a hardy annual, flowers rose, or rosy pink; the habit is prostrate or trailing. In an open, sunny position the seeds should be sown in the soil where the resultant plants are to flower. For a position such as our correspondent refers to (in the wild garden) there would be ample growth but fewer flowers, and the best plan would be to sow the seeds in a number of small pots in a frame and, in due course, transfer the plants in their pots to their flowering quarters. A nice ordinary loam will be suitable. Prepare the soil and plunge the pots containing the plants in it, burying the rims. Sow the seeds forthwith, plant out in May.

GREENHOUSE.

Physalis peruviana (W. P. W.).—This plant is a native of South America, but is naturalised in many warm countries. It was introduced to and cultivated at the Cape of Good Hope from where seeds were sent to New South Wales under the name of Cape gooseberry. It is a greenhouse climber, but grows freely in warm sunny positions outside in summer especially against a south wall or fence. In addition to seeds the Cape gooseberry is readily increased by cuttings. A preserve is made from the fruits, but it has never been very much grown in this country for the purpose, comparatively few being partial to the flavour.

TREES AND SHRUBS.

Pruning a Lavender Hedge (K. C.).—It will not be safe to cut the lavender hedge as low as our correspondent suggests, for lavender does not break well from the old wood. The best plan would be at once to layer sufficient of the lower branches to make a new hedge. They would probably be well enough rooted by autumn to remove and use as separate plants. Or cuttings may be inserted in a close but cold frame in June or July and planted to form a new hedge when large enough.

Restricting Tree Roots (D. D. O.).—A more lasting method of restricting roots is to make a wall of concrete 3ft. deep and 4ins. or 6ins. wide about 3ft. or 4ft. (or more) from the trees. The roots cannot get through this as they would through the sawdust in time. Or sheets of galvanised iron may be sunk and they take up less space.

THE HARDY FRUIT GARDEN.

Diseased Apples (Mrs. E. M. W.).—The cause of the brown spots which our correspondent mentions appearing under the skin of apples which are otherwise sound, is probably due to the presence of fungus. Several species of fungi cause the spots on apples in a characteristic manner, and it would be difficult to give the exact name unless we saw one or two specimens. Such fungi occur very commonly in cases of imported apples. It is rather unusual to find it occurring on freshly gathered fruit. When storing the apples, it is advisable to keep them in a cool place and allow plenty of ventilation.

MISCELLANEOUS.

Treatment of Cacti (A Novice).—Although cacti and succulent plants thrive better in a greenhouse, they may be grown with some success if placed in the sunny window of a room where the temperature does not fall below 45° Fahr. (In nature these plants grow where they are subjected to heat and drought during some part of the year. Water the plants only when the soil becomes dry, which may not be more than once or twice a week in summer. Very little water should be given during the winter months. A useful and instructive book dealing with the cultivation of these plants is "Cactus Culture for Amateurs," by William Watson (price 2s.).

Name of Plant.—J. H., I. of W.—Ruscus Hypophyllum.

Digitized by Google

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Beet.—The turnip-rooted variety may be sown in rows 1ft. apart, and, if the seed is sown thinly, no further thinning will be needed. The main crop of the long or intermediate varieties may also be sown during the present month, but 15ins. should be allowed between the rows, and the plants thinned to 6ins. in the lines.

VEGETABLES UNDER GLASS.

Tomatoes.—Seedlings that have been potted on will now be in pots 5ins. or 6ins. in diameter and ready for transferring to their fruiting quarters. About this date a house can be spared for tomatoes, and where the stages are suitable it is best to plant them out, otherwise pots of a large size will be needed. Turfy loam is an excellent rooting medium, and if pots are used space should be left for top-dressing later on when the plants have set a truss of fruit. Stout stakes are essential, and if these can be made fast to a wire near the roof they will remain in their proper place, and not bend over later on with the weight of the fruit. Admit plenty of air when the weather is favourable, and do not allow the roots to become dry. A watch should be kept for white fly, and only constant attention will hold it in check. Until the fruit is well advanced the plants may be sprayed with an insecticide and the house vaporised with one of the white-fly fumigants. Later plants may be potted on, and if intended for the open ground they should be grown in a cool house to produce stocky specimens.

THE FLOWER GARDEN.

Hardy Primulas.—Under this heading will be found a large number of plants, but, unfortunately, many of them cannot be termed a success in several gardens—for instance, the Chinese cowslip, P. Forrestii. However, some of the best are easily grown, and they include P. pulverulenta, P. japonica in variety, the beautiful P. helodoxa, P. Veitchii, P. Bulleyana and its hybrids. They are readily raised from seeds, and if sown about this date good plants will be available for next year. The seeds are sown in boxes of light soil, and they should be placed in a cold frame, well shaded, and never allowed to become dry. When the seedlings are large enough, prick them off in boxes or prepared nursery beds, and keep them free from weeds. It is a good plan to collect a little seed each year and raise a few plants annually.

Flower Beds should be weeded and any dead leaves removed, while the soil between the plants may be lightly stirred over. Grass edgings should be clipped and the lawn mown occasionally, and so give the whole a pleasing appearance. Hardy ferns may be lifted and divided if required. Water lilies may also be divided if overcrowded, and fresh loam given to any that require it.

Pansies.—There are now several fine strains of pansies in existence so that it is not the general rule to increase by cuttings but from seed. Sow the seed thinly in boxes or pans, and when the seedlings are ready prick them off in a cool part of the garden, and here they may remain until large enough for their flowering quarters. A rich soil is needed, and the position should be shaded from the midday sun.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Beans.—Kidney beans are held much in esteem as a vegetable, and where a south or west border is available a sowing should be made thereon. The soil should be deeply worked and well manured. Drills should be taken out 15ins. apart and 2ins. deep, and the beans placed therein at 4ins. distant from each other. We find Canadian Wonder a reliable variety.

Carrots.—The remaining section of the ground should be thoroughly raked, so that the surface soil for a few inches in depth is made fine. The drills should be drawn out 1in. deep and 15ins. apart and the seed sown thinly therein. To the varieties already mentioned in former notes may be added Altrincham, and those who prefer the stump-rooted type will find Guerande quite a good kind.

Onions.—Now that soil conditions are warmer, preparations should be made to have the ground in good order on which the plants raised under glass are to be grown. Plant in lines 15ins. apart, and allow a distance of 6ins. between each plant in the lines.

Tomatoes.—Many grow the love-apples in pots and boxes, and the old custom of only filling these receptacles half-way up at the time the young plants are put into them is certainly good practice. The remaining spaces should be filled when the plants are well advanced, as then they require extra feeding material.

THE FLOWER GARDEN.

Calceolarias.—The bedding varieties should be well watered, then lifted from the frames and set out a few inches apart in leafy soil in the celery trenches; this will allow frame room for various seedlings which require pricking off. Stakes should be placed across the trenches to support pea trainers or wire netting, so that frame mats or other covering material can be laid thereon as a protection to the plants when frosts threaten.

Nemesias sown last month should be pricked off into boxes filled with moderately fine soil. It is wise to take a little extra care in the cultivation of these plants, and on no account let them get drawn up in heat, but when established in the boxes keep them as hardy as possible until set out in June. Nemesias, to be effective, should be planted in beds or large patches. The variety Sutton's Hybrid Blue Gem grows from 12ins. to 18ins. high, and under good cultivation produces flower heads 8ins. in diameter. The pale blue colour of the flowers is most charming.

Violets.—Plants grown and flowered throughout the winter in pots or frames should be taken up now and the larger torn asunder, choosing the young and healthiest portions to replant. The ground on which the plantlets are to be set should be enriched with well decayed manure or leaf-mould, and the site selected should not be fully exposed to the sun. Plant in lines 12ins. apart, and allow 8ins. between each plantlet in the lines. A good watering should be given if the weather is dry.

Lawns.—Those contemplating sowing lawn grass seed should do so now. Where moss has been raked or daisies forked out, the bare places should be made up with old potting soil which has been finely sifted, and the seed sown thereon. A little of the fine soil should be sprinkled over the seed and gently beaten down with the back of the spade.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Reinwardtia tetragyna and R. trigyna.—These two yellow-flowered plants are natives of India and are specially useful and beautiful for winter flowering in the greenhouse. They are easily propagated at this time by means of cuttings, which root readily in a case with slight bottom heat. They should be potted on as required, 5in. or 6in. pots being large enough for the flowering size: they grow freely in any good potting compost and should be grown during the summer in a cool, airy greenhouse. They are very subject to attacks by red spider, which must be prevented by a free use of a syringe during bright weather. R. trigyna should be pinched several times to induce a bushy habit, while R. tetragyna throws up suckers from the base and does not require pinching.

Gardenias, at one time so popular, are seldom seen at the present day. They are generally regarded as stove plants, but they stand and flower freely at this time in the warm end of a greenhouse. Cuttings root readily in a warm propagating case. They should be grown in a temperature of 60° to 65°, pinching them several times to get well furnished, bushy plants. If grown on for several years they make fine large specimens.

Hippeastrums, which are so useful for greenhouse decoration during the spring months, should as they pass out of flower, be returned to a warm house and, if possible, plunged in a bed where bottom heat is at one's command, although this is an advantage during the growing season it is not really essential, as hippeastrums are by no means so difficult to grow successfully as many people imagine. Plants that are growing freely and are well rooted will take ample supplies of water, and should be fed with diluted liquid manure, alternated with some approved artificial fertiliser. Their successful flowering next season depends very largely on good cultivation during the growing season.

Azaleas of the indicum section, as they pass out of flower, should be placed in a house where a warm moist temperature can be maintained to encourage growth, a temperature of 55° suiting them very well. During bright weather they should be syringed several times throughout the day. This will encourage growth and prevent attacks by thrips, to which they are somewhat liable. As they finish their growth they should be accustomed to cooler conditions, to prepare them for being stood out of doors during the summer months. There are now quite a number of the small-flowered Rhododendron (or Azalea) obtusum—the Kurume azaleas being referred to this species. In cultivation they are very free flowering, force readily, and are very pretty for decorative work, having a charm which the large-flowered indicum varieties do not possess. They are easily propagated by means of cuttings of half-ripened shoots which root readily in sandy peat, plunging the pots in a case with slight bottom heat. They soon make useful plants and flower freely in quite small pots. There are some beautiful shades of pink and salmon to brick red among the Kæmpferi varieties, and it is surprising that they have been overlooked so long for greenhouse work. All the stronger-growing indicum varieties are just as easily increased by means of cuttings, and in the long run such plants are better than grafted ones.

JAPANESE CHRYSANTHEMUMS

IT is possible to grow Japanese chrysanthemums in 7ins. pots with very good results. This system of culture has several points to recommend it. The plants are useful for the front of greenhouse groups and are of a convenient size for house decoration. They give no trouble during the dark, trying days of winter and spring, as there is no need to insert the cuttings until the last week of March. Care is necessary in the treatment of the parent stock. Each parent plant should have occupied a light cool position during winter, and the strength of the cuttings is increased by top-dressing with loam in January. Each cutting should be inserted at the side of a thumb pot in the following compost: Three parts of loam, one part of leaf-mould and one part of sand. A greenhouse in which a night temperature of between 50° and 60° Fahr.can be maintained will supply suitable rooting conditions. I do not find it necessary either to shade the cuttings or stand them in a propagating case. As soon as the cuttings are firmly rooted they should be removed to a cold frame and —gradually, of course—be inured to an outdoor existence like the main batch of chrysanthemums. When the thumb pots become too small the plants should be repotted into a 4in. size, using a compost of two parts loam, one part leaf-soil, one part half-decomposed cow manure, and one part sand. No special cultural treatment is necessary between now and the final potting, which will be in the early part of June. The above compost, with the addition of a 5in. pot of bone-meal to the barrowful of soil, will be found suitable. Firm potting is conducive to the development of a sturdy growth, upon which so much depends. Feeding may commence about the second week in July and continue until the colour of the petals appears. It is well to ring the changes on fertilisers. Plants, like animals, appreciate a change of diet. My practice is to use dilute farmyard manure water, soot water, and a good proprietary chrysanthemum manure in turn, and feed twice a week. I never grow more than one flower on a plant, and I secure it by very simple treatment. If a bud develops before the third week in July it is removed and the strongest lateral shoot is retained for the production of a second crown bud. It is rare, however, that such a course is necessary. The majority of the buds develop in mid-August, which is an excellent time. Weather conditions will make it necessary to house the plants soon after the end of September. Cool, well ventilated conditions must prevail under glass. Chrysanthemums are intolerant of nothing more than a close, warm environment.

GEO. H. COPLEY.

BOOK REVIEW

THE MANURING OF MARKET GARDEN CROPS.

This little manual* should prove of service to the average market gardener, whose duty is to raise good crops with a moderate outlay. The subject is skilfully treated, each crop being dealt with separately—with a table showing the annual cost and the average annual yield per acre under the various methods of treatment with artificial fertilisers. The results have all been arrived at experimentally, having been carried out on one of the farms at Golden Green, Hadlow, Tunbridge, and go far in proving the considerable value of a dressing of artificial manures in raising market-garden crops.

*THE MANURING OF MARKET GARDEN CROPS, by Bernard Dyer, D.Sc., and F. W. E. Shrivell. New Edition, 1924. (G. Street and Co., Ltd., 1s. net.)

A Cup for Peonies.—Peonies are so comparatively easily grown that it is a matter of surprise that they are not more largely used in our gardens than appears to be the case. In America their value has been realised for some time, and there seems to be many enthusiasts who cultivate a great number of varieties. Among them the best known is Mrs. Edward Harding, who published in 1917 "The Book of the Peony" and, more recently, in 1923 a smaller volume on "Peonies in the Little Garden." So convinced is Mrs. Harding of the value of peonies for garden decoration that she has presented to the Royal Horticultural Society three cups, to be awarded in 1924, 1925 and 1926. The first is offered for competition at the R.H.S. Show on Wednesday, June 11th, 1924, for the best exhibit by an amateur of three flowers each of six varieties of peony. Medals will be awarded as the second and third prizes if the exhibits are considered to deserve them. It is hoped that Mrs. Harding's generous offer will encourage a keen competition among amateur growers of peonies. Entries should be received by the Secretary of the Royal Horticultural Society, Vincent Square, London, S.W.1, not later than the first post on the morning of Wednesday, June 4th, and all exhibits must be staged not later than 11 a.m. on the morning of Wednesday, June 11th.

International Spring Flower Show in Holland.—An international flower show is to be held in Holland in 1925. The General Bulb Growers' Society at Haarlem, which celebrated its half-centenary in 1910 by a two months' open air show in the Haarlem wood, is now organising an exhibition of an international character for next year. It will be held in a most beautiful and appropriate site, being a part of the Groenendaal Park at Heemstede, near Haarlem, affording a unique opportunity of showing many kinds of bulbous and other plants to their best advantage in natural surroundings. The open air exhibition will continue during two months, from March 13th to May 21st. Besides, there will be six temporary shows in a building specially constructed for the purpose. Each temporary show will be of a special character, three of which will chiefly be devoted to Dutch horticulture. The Belgian nurserymen and amateurs under the auspices of the Chambre syndicale des horticulteurs Belges, have already decided to organise real "Floralies gantoises" for the temporary show to be held from April 24th to May 3rd and it is expected that other horticultural countries will also arrange representative shows of their specialities in flowers and plants. Great Britain and Ireland will doubtless send cut flowers of their new and remarkable daffodils to the daffodil show to be held in April, but, besides, such grand specialities as carnations, sweet peas, roses, orchids, hippeastrums, etc., would make a brilliant display as a thoroughly British temporary show from May 15th to 21st, probably coinciding with the flowering season of the late tulips, which will be one of the chief attractions of the exhibition. Another feature might be a display of British rock gardens either outside in the permanent show, or in the building, and as there is a growing demand for such gardens just now in Holland, it would doubtless be the right moment to demonstrate what British taste and experience have produced in this line. The exhibition has H.R.H. the Prince Consort of the Netherlands as Protector and three State Ministers and two Governors of Provinces as Presidents of Honour.

AN INVITATION

MANY an old gardener has all the lore and the science of gardening at his finger tips. He can make plants grow and flourish as if he had grown them for thousands of years instead of during his short span of life. But although he may be able to make the desert flourish like a bay tree, he may be inarticulate. He could tell you the methods he employed, but there is more than method in his gardening. Other people could use the same methods and fail dismally, for there is a great deal in gardening beyond the ordinary rule of thumb: there is some subtle understanding between a grower and his plant which only comes from years of affection and contemplation.

Gardening is the most elusive of occupations. With many who live in the British Isles it is instinctive, for they have been bred and born among gardens, and their knowledge is not learnt by rote. Some, like Miss Gertrude Jekyll, Mr. Clutton Brock and Mr. Reginald Farrer, to name a trio whose names happen to run off my pen, possess the gift of being able to write about some of the subtleties which surround gardening like an intangible aura, but such lucky ones are like grains of sand among the masses who in their hearts feel the same subtleties but may not have the gift of expression, or rather may think that they do not possess it.

It is easy to write the bald facts about a plant: that it was discovered by someone at a certain date in Greenland or in Timbuctoo, that it flowered for the first time in z year and was duly shown at Vincent Square, that it will grow in peat or in the sea, that it has leaves 4yds. long and microscopic flowers, that it is propagated by cuttings and not from seed, that it grows better in the Shetlands than in Cornwall. This kind of information is simple, too simple, for the facts are thrown at one like bones to a dog. It is useful in the same way that a catalogue or a guide book is useful.

On the other hand, such facts are useless for the purpose of judging the subtle distinctions between the values of different plants. Personal taste is left out of the question, and personal taste is a governing factor in gardening. To take Miss Jekyll as an example: she has knowledge, she has taste, she knows her own mind. That is all common ground shared by thousands of gardeners, but she has some gift which is above the reach of many of us which gives her the power of capturing the spirit of a plant or of a garden and of describing it on paper for the benefit of fellow gardeners.

Given full or comparatively full knowledge of facts, it is possible to write that which is of infinite use, but the subtleties of the subject and the spirit which surrounds it can only be dealt with by the owners of gardens and by those who work in them constantly. We are sure that not one but hundreds of our readers are conscious of this aura and must of a surety be able to express it in words.

We can deal with the ordinary mundane subjects which are so necessary for the well-being of a garden, but we invite all our readers to help us to supply those little and sometimes intangible somethings which will assist all lovers of flowers to make their gardens even more beautiful than they were before. There is no garden in which there is no room for improvement; and, besides, everyone has some pet theory which he puts into practice with excellent results. A will have a little scrap of information which will dovetail into that which B already possesses. A may grow a rose to perfection, which B also loves but may not be so successful in its cultivation. You may be sure that B will have something to give in return.

This is the same theme of co-operation of which I have written before, but it really is all-important for the improvement of our gardening knowledge. It is for this reason that we invite our readers to send us notes, whether long or short, upon the gardens and plants which they love so well. It matters little whether the plant be rare or common to every garden. Our knowledge of the vagaries of even the commonest plant is not so extensive that the subject is finished and done with, and no story of a plant or a garden is ever completed.

Everyone has some gardening need, something which will help to make his garden more attractive, perhaps some particular plant which ought not to be afforded, but which none the less is coveted. We shall be glad at the end of each year to give an order for £5 for anything advertised in our pages to the contributor who sends in the best note during that year.

SOME EARLY-FLOWERING BULBS

BY W. R. DYKES.

IF in these days I could arrange a garden for myself, I should confine myself to shrubs, bulbs and to such herbaceous plants as are self-supporting. Plants that need careful staking at an early stage are always troublesome, for it may not be easy to do the work just at the right time and, once that time has passed, the plants get out of hand and never look their best.

Bulbs, however, are self-supporting, and, even if some of them need lifting annually, this has its advantages, because it gives us an opportunity of rearranging our borders and of obtaining more pleasing effects. Permanent plantings in thin grass of snowdrops, crocuses, scillas, fritillarias and narcissi are delightful in early spring, and are certainly to be recommended, provided that the piece of ground is in such a position that the grass can be left uncut until the leaves of the crocuses and narcissi have turned yellow and collapsed. Then the grass may be scythed and subsequently mown with a machine.

THE SNAKESHEAD FRITILLARY, F. MELEAGRIS.

If this arrangement cannot be contrived, the alternative seems to be to have a lawn of irregular outline surrounded by deep borders of flowering trees and shrubs. In front of these and in bays between them many bulbous plants will succeed admirably, and in warm light soils the experiment can be tried of leaving in the ground such bulbs as must usually be lifted in order to induce them to flower. The effect of planting these bulbs among the roots of the shrubs, or rather where the roots of the shrubs will run among them, is that in summer the moisture is sucked out of the ground and that the bulbs obtain the ripening which is essential to their success. In these positions such plants as Tulipa saxatilis, the beautiful Cretan species, with its pale mauve flowers and striking yellow base may remain undisturbed with a good chance of flowering nearly every year. In the open border they always remain flowerless unless the bulbs are lifted and kept warm.

Tulipa Kaufmanniana is one of the easiest of all the wild species of tulip. The bulbs may be planted 6ins. or even a foot deep and left to themselves for several years. It is generally at its best in March, although in this late season it is nearly a month late. Usually the flowers are white inside with a yellow centre like a water lily, and more or less vividly flushed with bright red on the backs of the three outer petals. Others, however, are wholly yellow inside and others, again, wholly scarlet both inside and out.

Of scillas the commonest are bifolia and sibirica. Bifolia is the earlier and has starry flowers of a somewhat dull slate blue. Sometimes among collected bulbs specimens appear with crimson anthers, to which the varietal name of taurica has been given. This is certainly a pleasing variety, though the difference is only apparent on fairly close inspection. Scilla sibirica is rather later and the colour much more brilliant; in fact, it is almost a Prussian blue.

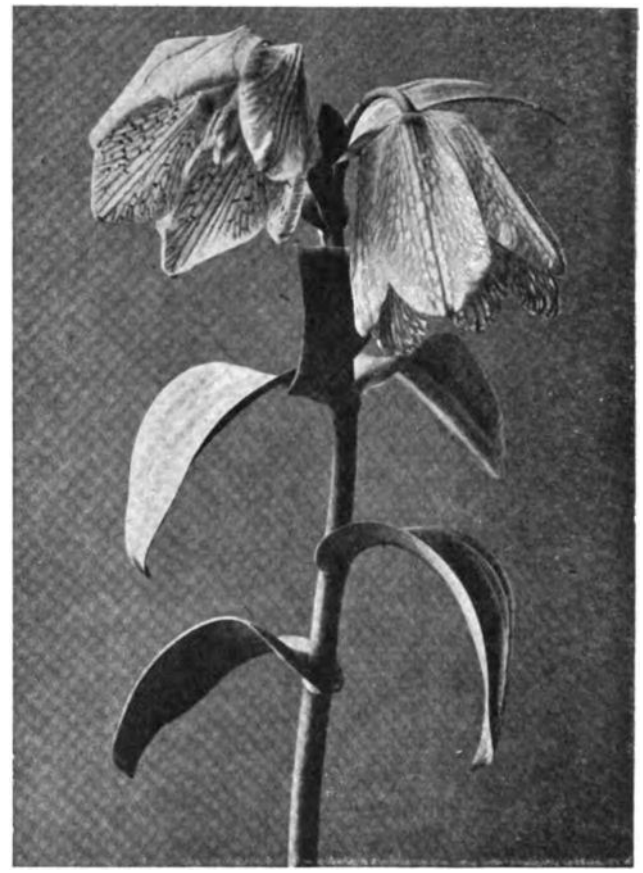
SCILLAS AT THE FOOT OF A TREE. THEY BLOOM BEFORE THE FOLIAGE OF THE TREE APPEARS.

Closely allied to the scillas are the chionodoxas, and their affinity is proved by the fact that, when scillas and chionodoxas are grown together, hybrids between them always appear sooner or later. To the eye the chief difference is that in the scillas the anthers stand out separately, while in the chionodoxas they are crowded together in a white cone in the centre. The earliest of the chionodoxas to flower is sardensis, which comes not from Sardinia, as might be supposed, but from the neighbourhood of Sardis in Asia Minor. The flowers are relatively small, but of a brilliant blue colour, relieved by the white central cone of the anthers. C. Luciliæ has large flowers, of which the blue colour at the tips of the petals fades to white at the centre, while the so-called gigantea has larger flowers, usually somewhat similarly coloured, but sometimes wholly of a soft shade of a rather dull Wedgwood blue.

Digitized by Google

Another blue-flowered bulb is the muscari, of which the pale blue varieties are very charming. Less frequently grown are some dull yellowish-flowered species, of which one is probably M. moschatum. These need, unfortunately, a very hot dry position if they are to do well, though their scent is so wonderful that it is worth while to grow them in pots in a cold greenhouse. Hybrids between these scented species and the well known variety Heavenly Blue would be very desirable, but it does not seem easy to make the cross. In the garden a very telling effect can be produced by planting muscaris thickly round bushes of Forsythia intermedia.

Fritillarias are strangely neglected. It is true that the yellow and scarlet Californian F. recurva only goes on from year to year in light, warm soil, but nothing could be easier than F. Meleagris, which grows wild in the meadows round Oxford and of which the white variety is particularly pleasing. In some gardens this fritillary seeds itself freely, and its growth is so light and slender that it is never in the way. An equally easy plant is F. latifolia with broad, hanging bells of dark reddish purple or yellowish brown. The colour is always lighter inside and the chequered markings more conspicuous. F. pyrenaica is taller and more graceful, and quite easy to grow in the open border. The best of all fritillarias is perhaps F. pallidiflora, a Turkestan species with very glaucous foliage and among the upper leaves six or seven large pale yellow bells. This species especially deserves to be much more widely known and grown, and it would be if only gardeners realised that it has the peculiarity that its bulbs are only rootless for a very short period; in fact, for only about a fortnight, and that this period begins almost before the stems have collapsed. Therefore the bulbs must only be moved while they are rootless during this period, for if they are dug up later in the summer, when the new roots have grown, they will receive a check from which they do not easily recover. If the bulbs must be kept out of the ground for some time, each one should be wrapped in thin paper, and this will enable them to be replanted without damaging the roots, which will be found to have grown to some length. The same treatment is very useful when crown imperials (Fritillaria Imperialis) have to be dug up, and there is no doubt that in many gardens these fine plants flower much more freely when they are dug up and replanted every year. Any bulb which is entirely rootless at some period of the year must obviously do better if, during that period, it is shifted into a position where its roots will push out into fresh soil. Some dislike the scent of the crown imperial, but to others it resembles that of coffee and is by no means displeasing.



ONE OF THE BEST FLOWERING FRITILLARIAS, F. PALLIDIFLORA.

CHIONODOXAS *alias* GLORY OF THE SNOW *alias* "CHINIEDOXIES."

Scented flowers are always attractive, and an effort should be made to grow Hermodactylus tuberosus, of which the beautiful green and velvety black flowers are strongly honey-scented. These appear in March and April from among what look like the leaves of strong-growing clumps of Iris reticulata. The curious, finger-like tubers give the plant its name, and my experience is that the flowers are not numerous unless the tubers are lifted when the leaves collapse and replanted late in August or early in September. The flowers resemble those of an iris in shape, but there is a botanical difference in the formation of the seed-vessel that makes it impossible to include this plant in the iris genus.

Even earlier than any of the bulbs already mentioned come crocuses, especially if we value shape, colour and markings above mere size, and therefore grow the wild species instead of the garden varieties of Crocus vernus, which with the common yellow are the only crocuses to appear in many catalogues.

One of the best of all the early spring crocuses is C. Imperati from the neighbourhood of Naples. The flowers are large and usually of a light buff on the outside, more or less conspicuously marked with three branching veins of dark purple. The flowers are a bright lilac colour inside, and one of the merits of this species is that each corm produces several flowers in succession and that the corms themselves do not all begin to flower at the same time. A large patch of C. Imperati will therefore usually provide flowers for more than two months. There is also a very fine white variety of this species. The outer petals are slightly tinged with cream on the outside, but otherwise the flowers are pure white. A few bulbs of this variety were sent to me originally from Naples, and, as I found that it reproduced itself from seed, I have been able to give away corms to friends. Crocuses do well in rather rich, light soil, and are all the better if they are replanted about every third year.

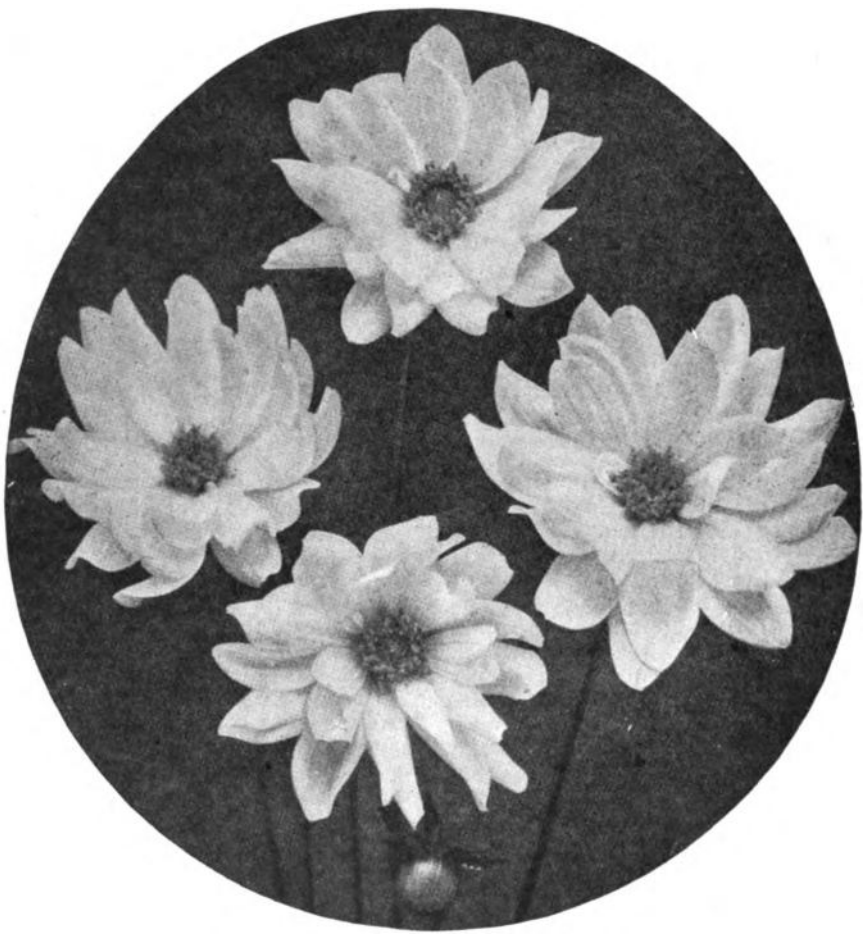
POPULAR DAHLIAS

(*Continued from page 239.*)

STAR DAHLIAS.—Of the numerous classes of dahlias most people have a preference for one or more, in which they may specialise, and I need only give, at the most, a selection of the principal classes. The Star dahlias are infinitely beautiful as garden plants, on account of their graceful habit, free flowering character, and the manner in which they carry their flowers above the foliage on stiff, wiry stems; and for these reasons they are most elegant and graceful in the cut state. Crawley Star was the first introduction of this race and its clear pink flowers are charming in artificial light. A beautiful combination of tangerine-orange and copper is met with in Surrey Star, which has been honoured with a first-class certificate. The colours are indicated by the names in White Star, Mauve Star, Primrose Star and Bronze Star, the latter being an introduction of last year. Most of these have a fine habit of growth, and so have the crimson, apricot and purple Southern Star, and the apricot and pink Reigate Star. Autumn Star is terra-cotta, shaded with red, resembling beautiful autumn tints; and a rosy purple variety of perfect habit has been named Eastern Star. A charming variety for table decoration with soft salmon-pink flowers, was introduced last year under the name of Dorking Star. All of the above resemble single flowers, with several rows or tiers of rays, slightly incurved or cupped, and that, along with their varied and beautiful colours, has greatly taken the public fancy.

GARDEN CACTUS DAHLIAS.—Since the introduction of Dahlia Juarezii about 1879, an immense advance has been made in the development of a new race, most beautiful withal, but with flowers giving trouble in bending their heads and hiding them among their foliage like the original. The beauty of the incurved, whorled or spreading-petalled varieties of the show Cactus dahlias is transcendent, but they have always given trouble in this respect. The garden Cactus varieties have been selected for beautiful colours and erect stems, produced freely and standing well above the foliage. The best white for garden decoration is Alabaster, but three others have enjoyed a considerable run of popularity, namely, Mrs. D. Fleming, Snowdon and Silverhill Park, the latter being introduced in 1921, and much newer than the other two. The scarlet Mary Purrier, the exquisite pink Sweetbriar, the pinkish-salmon Arthur Pickard, the crimson-maroon Conquest, the reddish-orange F. W. Fellowes, the fine scarlet Sportsman, and the light orange Thos. Parkin are all popular and beautiful varieties. Others not less desirable are Edith Carter, yellow, shaded rosy carmine; Golden Wave, deep yellow; and Iris, orange, shaded with scarlet.



WHITE STAR, A POPULAR VARIETY.

POMPON DAHLIAS.—This class originated about 1850, but many of them were still of rather large size in 1880, though they were then numerous. Since that date the aim has been to obtain varieties with small, neat and compact flowers, and many of this type are practically perfect. They are equally good for garden decoration, cutting or exhibition. Handsome ones are White Aster, Tommy Keith, red, tipped white; Nerissa, pale rose; Mars, rich scarlet; Irene, soft rosy mauve; Electra, deep orange; Darkest of All, maroon; Daisy, amber; Little Beeswing, yellow, well edged with red; Ideal, clear yellow; Glow, salmon-cerise or rich coral; and Bacchus, a beautiful crimson-scarlet, though not so free as some of the others.

LARGE DECORATIVE.—These are large varieties, often with flowers rather flat on the top, though the aim is to have them nearly hemispherical, or similar in shape to a camellia. They range through all shades of colour, carrying their flowers more or less erect and make a brave display in the garden. The florets are much less quilled than those of show dahlias and are often nearly flat when fully developed. Two of the largest and brightest are Souvenir de Gustave Douzon, reddish scarlet; and President Wilson, vermilion-scarlet. A lovely rose pink, beloved by everyone, is Delice. White Cloud, Orange King and Brentwood Yellow, bespeak their colours, while Pearl is a pale silvery rose. Queen Mary is a beautiful and soft shade of pink. A shade of violet or violet-blue pervades Porthos, making a distinct break in colour. Other excellent varieties are Paul Crampel, brilliant scarlet; Ben Lomond, another of a violet shade; and Mrs. Sturdy, an introduction of last year, yellow, shaded with amber.

COLLARETTE DAHLIAS.—This class is characterised by a ring or collar of florets that are deeply divided and elongated, but always shorter than the rays, and usually of a different colour, which makes them more durable than single flowers, and more suitable for cutting, while they are equally handsome for garden decoration. Choice varieties are Princess Louise, crimson; Diadem, rose; Queen Bess, orange scarlet; Regularity, purplish crimson; Tiger, white, edged with scarlet; Holyrood, scarlet, with yellow collar; Henri Farman, yellow, blotched with red; Madame Poirier, blue, with white collar; Admiral, nearly black with a pure white collar; Vera, bright yellow; Glenlyon, white, banded with orange; and Eden, which is choice with its pure white blooms.

SHOW DAHLIAS.—These include all those massive, hemispherical, and beautifully quilled dahlias which delighted the

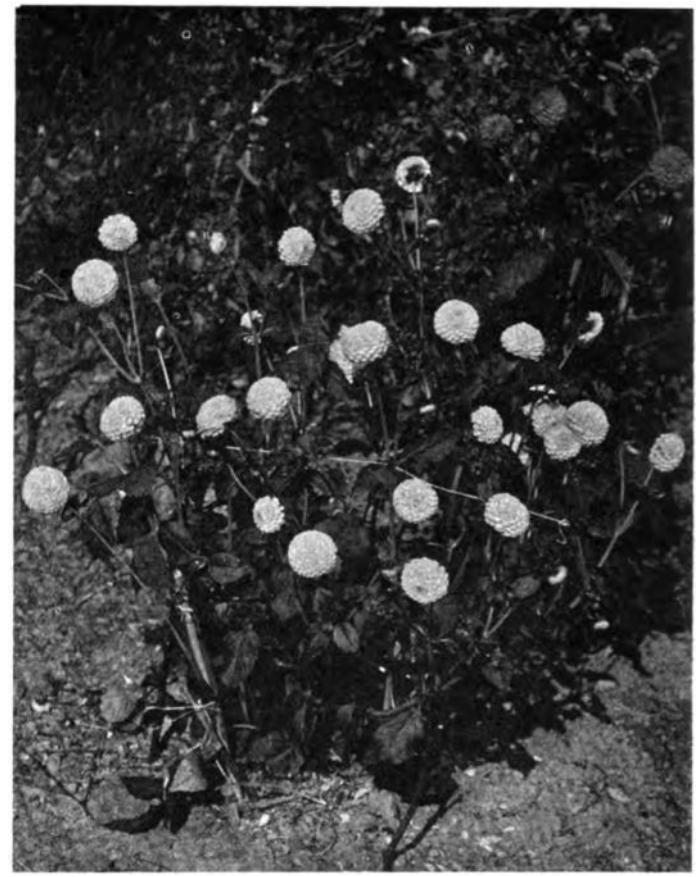
ONE OF THE COLLARETTE TYPE, ADMIRAL.



POMPON DAHLIA, IDEAL.

florist during the past century, and though they are not grown to the same extent now, they were the first of the dahlia varieties to reach perfection in the eyes of the florist, and because they were first in the field they enjoyed universal popularity in the British Isles. Shapely and handsome varieties are Warrior, brilliant scarlet; Gracchus, orange buff; Mrs. Gladstone, soft blush; Willie Garrett, cardinal red; Mr. Chamberlain, dark maroon; John Walker, the best white; Harry Keith, rosy purple; Florence Tranter, blush, edged purple; and A. M. Burnie, orange. Very handsome fancy varieties are Mrs. Saunders, yellow, tipped white; Mrs. J. Downie, orange, striped with scarlet; and Goldsmith, yellow, striped crimson.

SINGLE DAHLIAS.—Some of the most beautiful singles are William Parrot, orange-scarlet, tipped white; Butterfly, pure white; Owen Thomas, crimson-scarlet, tipped white; Leon, glowing scarlet; Flora, orange terra-cotta; Brenda, white, edged scarlet; Eileen, white, edged rose; Fugi San, bronzy yellow; Snowdrop, white; Red Cross, white, edged with glowing red; Beacon, golden yellow; and Hilda, of a dainty flesh colour, with a yellow margin.

Besides the various sections mentioned there are the large peony dahlias, good examples of which are Lady Denman, scarlet, flushed and edged yellow; and Dr. Tongue, scarlet, suffused with gold. Then there are the miniature-flowered peony dahlias of which Leonie Cobb, pink, and Lady Beatty, salmon-pink, flushed rose are fine sorts. In 1922 a new type of dahlia was raised, it is called Novelty and might be termed a double collarette. The colour is crimson-scarlet. J. FRASER.

THE BEST HARDY STONECROPS

BY DR. LLOYD PRAEGER

NOT long ago the Royal Horticultural Society issued in its Journal an "Account of the Genus Sedum," on which I had spent a good deal of time. It ran to over 300 pages, with 185 figures, and it seems quite likely that many a modest gardener, alarmed by such a portentous presentation, may have been scared away from this useful and interesting group of plants instead of being attracted towards it. I venture to think, therefore, that a few notes on the group and an indication of its more valuable constituent species may serve a useful purpose.

First of all, one must be very cautious about sedum names. The nomenclature of the group in gardens is still utterly confused. The commonest species masquerade under all sorts of false colours, and if you would escape disappointment, shun alluring appellations, charm they never so sweetly. See your plant before you buy it. In many English lists half the names really refer to one or other of seven very common species—acre, album, reflexum, rupestre, sexangulare, spurium, Telephium—all of which are quite easily recognisable. There is no excuse for the confusion which exists.

Let us take the sedums group by group and make a selection of those which are best worth growing, and which are obtainable, hardy and good "doers." First comes the section Rhodiola, of which the well known roseroot of our mountain rocks is the type. These are very interesting plants botanically. The stems are extremely fleshy, sometimes elongate, sometimes forming a congested mass at ground level; they produce neither flowers nor leaves directly, their leaves being mostly reduced to mere chaffy scales. The leaves and flowers are borne on annual shoots arising from the axils of these scale-leaves. Quite the best thing in this section is S. Kirilowii var. rubrum, from Turkestan, with flat flower-heads of a unique bright brown-red. In nurserymen's catalogues it usually appears as S. linifolium rubrum or S. Rhodiola linifolia rubra. Then our native roseroot, S. roseum (=S. Rhodiola=Rhodiola rosea), well deserves a place, with its handsome glaucous foliage and yellow panicles of bloom. S. trifidum, from Himalaya and China, is an attractive plant, producing annually a few upright stems with toothed leaves crowded on their upper part and loose heads of red flowers; but it is not over easy

Digitized by Google

in cultivation. Care is also desirable in the case of S. primuloides, from China, which forms a tiny bush, the scale-leaves being replaced by flat diamond-shaped green leaves. Its white bell-shaped flowers are usually not so freely produced as one would like. Most of the remaining Rhodiolas found in cultivation are rare and do not grow freely.

The section Telephium is exemplified by the well known and native orpine or livelong, and its members are valuable in the rock garden because they are late bloomers—August to October. The group is especially characterised by its very fleshy tuberous roots. The two best are S. spectabile and S. Sieboldii, both from the Far East—the former with massive, erect, leafy stems and large flat heads of purply pink flowers, beloved of Red Admirals in September; the other with low, arching stems and roundish leaves in threes, a favourite pot plant, and often seen in cottage windows, sometimes in a variegated form. The orpine, S. Telephium, also is by no means to be despised, flowering as it does when blossom in the rock garden has become very precious. The European S. maximum, which typically is very like an opposite-leaved green-flowered orpine, has a range of purple-leaved often pink-flowered variants; these are effective, especially the very large form, with stems 3ft. in length and leaves in triplets, known as var. atropurpureum. S. Ewersii, from Siberia, a low twiggy plant with opposite roundish leaves and rosy flower-heads, is like the other Telephiums, late blooming and effective.

Next comes the Aizoon group, consisting of half a dozen yellow-flowered flat-leaved species from the Far East. Several of these are useful and well known plants: S. Aizoon (=S. Maximowiczii), with tall, erect stems like a yellow orpine; S. kamtschaticum and S. Ellacombianum, lower plants of tufted growth, the former with dark green sharp-toothed leaves, the latter with light green blunt-toothed leaves; and S. hybridum, much like these two but with creeping rooting stems. S. kamtschaticum has a variegated form which is one of the most effective of stonecrops.

We now come to the large and varied group Seda Genuina or Eusedum, to which belong all our common creeping species and others besides. Their leaves are flat or subglobular or sausage-shaped, and their flowers white or yellow or green or red. It is in this group in particular that erroneous names abound, and for the fourteen species which I am about to refer to at least fifty names are found in English catalogues. To take the white-flowered species first, we have the very common S. album, which, though variable in leaf, is always easily recognisable, and has no claim to all the names that are bestowed on it. The most valuable form for the garden is var. murale,

THE CURIOUS FOLIAGE OF SEDUM REFLEXUM.

with purple copper leaves and pinkish flowers—a very distinctive plant. S. Lydium is one of the tiniest of sedums, forming a fresh green mat, in exposed places tinged bright red. S. dasyphyllum and its ally S. brevifolium are really choice, tiny species needing a warm, very dry place, such as an old wall, in which situation the former may be found wild in southern England. S. dasyphyllum forms small pinkish grey tufts of egg-shaped leaves and white flowers; while S. brevifolium is smaller still, with white and red mealy globular leaves. S. populifolium, from Siberia, is an attractive plant of unique growth among hardy sedums, forming a deciduous twiggy bush up to a foot in height, with aspen-shaped leaves and clusters of hawthorn-scented blossoms.

Of red-flowered members of the Seda Genuina the dark-flowered form splendens of the familiar S. spurium gives a very fine patch of colour; and S. stoloniferum, allied to spurium and often confused with it, makes a fine mass of narrow-petalled pink stars. It is easily known from spurium by its smaller pale green untoothed leaves and wide open flowers. Very different is the North American S. pulchellum, with fresh green linear leaves and showy bright pinkish four-petalled flowers set on radiating recurved branches at the summit of 6in. stems. Unlike most sedums, this plant is fond of a damp spot.

Then there are a lot of yellow-flowered species, including the very common SS. reflexum, rupestre, sexangulare and acre. Forms of the first two constitute much of the rubbish that is sold under a multitude of spurious names. S. sexangulare is valuable on account of its neat green mats of foliage and profusion of golden bloom. The native S. acre has an interesting variety majus from Morocco (often named Maweanum) with much larger pale green leaves, which is worth a place in a choice collection. S. amplexicaule, which hails from southern Europe, is a curiosity, as it dries up in summer into a tangle of thread-like stems and grey slender buds, which in autumn again break into hair-like leaves with a peculiar sheathing base. S. spathulifolium and S. oreganum (often misnamed obtusatum) are two good yellow-flowered plants from the north-western United States. The former has diamond-shaped mealy leaves in lax rosettes. Its variety purpureum, larger and with the leaves flushed purple, is quite one of the best sedums in cultivation. S. oreganum has green spathulate leaves flushed with red, and forms a pretty mat. Lastly, of this section, the Moroccan S. multiceps may be

ONE OF THE MOST LOVELY OF THE SEDUMS, S. SPATHULIFOLIUM.

Digitized by Google

SEDUM ROSEUM, A NATIVE SPECIES.

mentioned, a linear-leaved plant forming a minute branching bush of curious appearance.

Finally, we reach the sections Sempervivoides and Epetium, which consist of biennial or annual species, and furnish three plants well worth growing. S. sempervivoides and S. pilosum are biennials, producing in the first year downy rosettes much resembling those of a sempervivum—lax with broad leaves in the case of the former, dense with narrow leaves in the latter. In the second year they send up one or several flat heads of flower, scarlet in sempervivoides, rose-coloured in pilosum. Although biennials are out of place in the rock garden, the beauty of these two Caucasian species demands an exception in their favour Lastly, there is one annual sedum which cannot be omitted from a good collection—S. cœruleum. It forms a tiny bush a couple of inches high, and alone in the whole genus has blue flowers. A clump of it when growing in the sun with red-tinged leaves and innumerable tiny sky blue stars is a lovely object. Like S. pulchellum, it likes a moist situation.

From among the sedums known in cultivation—in number 150 species or so—I have in the above notes selected thirty as best for the English rock garden: as being attractive, hardy, obtainable and easy under cultivation. Of course, tastes differ, but speaking from a wide experience of the genus, I do not fear criticism. The selection stands as follows: S. Kirilowii rubrum, roseum, trifidum, primuloides, Telephium, maximum atropurpureum, spectabile, Sieboldii, Ewersii, Aizoon, kamtschaticum variegatum, Ellacombianum, hybridum, album murale, lydium, dasyphyllum, brevifolium, populifolium, spurium splendens, stoloniferum, pulchellum, sexangulare, acre majus, amplexicaule, spathulifolium purpureum, oreganum, multiceps, sempervivoides, pilosum, cœruleum. These vary in height from an inch to 3ft., and include carpeters, clump-formers, bushy plants and erect herbs; the majority are evergreen, and all but the three last perennial. In leaf they are of many shades of green, glaucous, purple or variegated; in flower white, yellow, orange, pink, purple, scarlet, blue. The flowering period of the series extends from June till October.

I have only one word to add. In the milder parts of the British Isles some of the Mexican sedums are quite hardy, and in a warm, dry place will enhance any collection. The kinds most to be recommended for hardiness and appearance combined are S. confusum, S. compressum, S. Palmeri and S. retusum; but these plants are not readily obtainable, though now included in a number of British collections. The first three have the merit of flowering in April, two months before any of the Old World species.

THE ESSENCE OF SPRING

THE war, with its immense upheaval of so many recognised things, wrought much evil in our gardens; but it was (as time and distance have proved) an evil out of which good has come. Pre-war—most hateful phrase, though useful—the garden boasted a border, filled each autumn with bulbs in quantity, that for weeks was gay with the finest daffodils, tulips, etc. To-day, no vestige of its former glory remains; but a more satisfying array has replaced the old-time bulbs, that being nothing less than a collection of old-fashioned hardy border flowers, which have come to be known by the name that heads this article.

I do not regret the past, the present is too rich; and—while the remainder of the garden is but waking and making ready — thither I direct my steps to the fulness of spring actually in being and rich with promise of still more to follow. Though old-fashioned flowers have been so largely used, this does not mean that only old varieties appear. Far from it, for I have searched and searched again for the "best" of everything that blooms during the youth of the year, and, while much that was familiar to our grandfathers is lavishly employed, wherever anything that is strikingly better has been achieved, it is that which has been chosen.

As an instance, the old-time Alyssum saxatile was a gay old plant; but its modern descendant—plenum—is a much better one and figures in great stretches of grey foliage that now are literally sheets of gold dust. One can afford to be lavish in one's use of this, for it is an all-the-year-round plant and very decorative all through the summer and a welcome spot of brightness on the dullest winter's day.

Life and flowers are so abundant on all hands that it is difficult not to be distracted hither and thither; but let me concentrate on the dwarfer material first. Forming dense low-growing patches, not more than two or three inches high, Adonis vernalis is freely used, and its golden yellow flowers are among the most welcome contributions of early spring. The leaves are fern-like; but, in this respect, Adonis amurensis is a far finer plant, and liberal use has been made of this, too. The fact that the border was originally composed of bulbs gives an initial supply of those which are more or less permanent in character, and hard by the patches of Adonis are masses of the thin grass-like leaves that mark the spot where Fritillaria Meleagris holds court. These go on, year after year, and although they do not increase much, they do not become less, and April and May never fail to produce a wealth of those large pendent tessellated bells that are so unique. These are, indeed, flowers to earn our love, and three or four blooms cut and placed in a clear glass "specimen vase" are a joy to rejoice the artistic soul. How marvellously the petals are chequered. How strangely they vary in depth and how exquisite are the white varieties in which this chequering is only hinted at in palest green.

Considering that the soil is such a light one, you may, naturally, express surprise to see those wonderful sheets of hepatica in white, blue and vivid pink. It really does seem as if they were intent upon hiding the fact that they possess foliage, and the question is often asked: "How can you do it on this soil?" I cannot. It is accomplished by means of one of those "little dodges" so familiar to the keen gardener. I needed hepaticas—needed them badly—and so the natural earth was removed to a depth of 15ins. and replaced by several spadefuls of rather heavy loam mixed with a little leaf-mould, and—there you see the hepaticas, and they entirely justify the trouble.

You will have gathered, by this time, that every good thing which can be pressed into the service of the "essence of spring" is used without hesitation, so that it will be no surprise to find great patches of the annual Silene pendula bursting with buds and which will give sheets of intense vivid pink that endure for weeks. This, of course, is sown in August, just to make sure; although, by allowing Nature to take her course and

Digitized by Google

by leaving the old plants alone, it is seldom that the supply of self-sown plants is short. I scarcely need to comment upon the forget-me-nots (please forget that the botanist calls them myosotis); they are self-evident, and, where these break into and intermingle with the silene, one has a charming picture indeed.

February and March gave the common primrose, reinforced by the coloured forms and particularly the blues in plenty; but to-day, interest centres round the polyanthus. Here are riches without stint, more especially as one can purchase the seed separately, more or less to colour. I would not claim that this is "true." It is not, but it does enable one to plant great sweeps and drifts of dark reds, crimsons, yellows and whites, that thrust up their flower heads in great sheaves and, by the very density of their massing, call to one from afar. Here, again, the "blues" are prominent, and he who will take the trouble to isolate his seed plants can work up a splendid strain of really clean colours that is a long way ahead of the "blues" supplied by the nurseryman.

Still among the primulas, another reliable perennial species that provides us with something "quite different" is to hand in P. denticulata. Happy is the border where a couple of dozen or so of these flourish in one group. The foliage rather resembles the ordinary primrose, save that it is always distinguished more or less by mealiness, a feature that becomes so pronounced in some specimens that it is as attractive and beautiful as the flowers. The flower heads are circular, borne on very stout stems, and

ADONIS AMURENSIS WHICH FORMS DENSE LOW-GROWING PATCHES.

a lovely bright lilac that is distinct in hue from any other flower of its season. Of course, another primula bulks large throughout the scheme of planting—the auricula. These originally were planted as seedlings in mixture, but to-day I have improved upon that. Propagation by division has enabled me to sort up the colours, and now they stand in large tufts of browns, deep crimsons, mauves, rich yellows, etc., set in those large rosettes of leathery leaves that add so much to the floral beauties.

From the ethereal to the solid is only a short jump, and we come down beside yet another grow-anywhere plant in Bellis perennis, in white, pink and crimson. Before winter has released its grip, these are flowering and will carry on, becoming smaller and smaller in their endeavour to keep going until summer has well begun—a grand old flower to which we owe a deep debt of real gratitude. And now attend closely, please, for here we have a curio—nothing less than the hen and chickens variety. This not only produces the large double flowers with which we are all familiar, but, clustered round this, a number of short stalks appear, and they, too, bear smaller double blooms. The double white arabis is too good to exclude, but we must keep a sharp watch upon it or it will certainly overrun its neighbours, to their detriment. A severe clip back with the shears after blooming, however, does much to check this rampant luxuriance, improves the plant and protects its neighbours, and the billowy masses of snow white flowers are well worth this small demand. Similar treatment is meted out to the aubrietias, and, in return, they lavish upon us circles and ovals of every possible shade from royal purple through warm crimson to lilac and the softest mauve. Use these lavishly, and dibble in among them any spare tulips of suitable colour and stature that you can spare, and you will gather a colour feast of inimitable richness.

Cropping up all over the place are anemones in variety. Not the brilliant tuberous forms, though these are good for select positions, but such gems as apennina, Pulsatilla, sulphurea and sylvestris. At the start there was a certain amount of order in their grouping, but now, happily, my efforts have been overruled and little plants have chosen their own homes and peep out here and there from the edging or the base of other plants in a manner that is charming and attractive.

That shaded corner, which appears to be barren, is a delusion, and a few days' warm sun would expose its falsity: for that is where the lilies of the valley flourish, and up will spear those closely rolled twin leaves and fragrant flowers that never lack appreciation. Near by, because they appreciate similar conditions, but much more advanced in their programme, are the trilliums or wood lilies—a host in themselves—upon the large flowers of which it is always a temptation to expatiate.

But I must hurry on to the taller growers: for, rich as the array of dwarf plants has been, there is still much to see, and we may now lift our eyes and look. Those shrubby sheets of dark green leafage, buried beneath their showy canopy, are the perennial candytufts, and you will not be long in noticing how soon the bees, both the great humble and the hive forms, get busy supping their nectar. No trouble with these, at any rate, for the soil in which they will not flourish has surely yet to be discovered.

Wallflowers! Ah! What a name, and what a plant! These are not the mean little specimens used for bed filling and torn up to make way for impatient successors. This is the wallflower as a *perennial* plant, given full opportunity to reveal its capabilities. This, reader, is where I get height and colour too. Great bushes 3ft. tall, smothered by a welter of sprays of blood red, brown, striped golden yellow, primrose and violet. Even as we watch, a hibernated example of the lovely brimstone butterfly skims overhead and descends—guided by its colour instinct to the palest primrose, there to expand and close its wings in the warm sunlight. Before leaving the subject of wallflowers, we must comment upon the grand doubles in their sturdy formality, stiff and upright as stocks and a fine chestnut red and golden yellow. These are uncertain in their flowering; but, with a warm and rather sheltered position, do well in average years, and one does not grudge the trouble entailed by sowing a packet of seed each May.

Not far away is another stock-like plant that gives grand heads of double white flowers at the minimum of trouble—the white rocket. This may be propagated either by taking cuttings and rooting these in a cold frame immediately after flowering, or by division of the older plants. This is only necessary once in two years, however. Among the taller plants, those stout stems, encircled by whorls of shining green leaves, reveal the presence of Fritillaria Imperialis—the Crown Imperial. Towering upwards to a height of 3ft., the stem is encircled at the top by a complete ring of large bright golden or dusky orange flowers, surmounted again by a further tuft of the green leaves that look as if they had been thrust through the ring of flowers as an afterthought. The common old honesty can be used in masses in the background, care being taken that the seeds are all from purple flowers, because this *en masse* is a telling hue of great value that is lost in the whites.

Finally, all those dwarf tufts of glaucous foliage represent Iris pumila, of which the flowers are nearly as large as their taller brethren, although they do not exceed 15ins. in height. These provide a marvellous show of royal purple, lavender, sulphur, yellow and white, for two or three weeks. Do I regret my bulb border? I do not. Essence of Spring is more than compensation. H. W. CANNING-WRIGHT.

DROPMORE AND ITS CONIFERS

AS this is the year of the Wembley Exhibition there will be thousands of visitors from overseas who may wish to see something besides London and the packed crowds at the Exhibition. In that case we advise them to visit Dropmore, which, owing to the kindness of the owner, Mr. Fortescue, is open to the public on Mondays, Wednesdays and Saturdays from 11 to 5. As it is only a mile or two from Maidenhead, it is within easy reach of London.

We visited the grounds in early spring, when the photographs were also taken, but even at that unbecoming time of the year, the impression gained was entirely that of amazement. A Canadian, who has lived with trees all his life, was in our party and his one remark was that he had never seen finer specimen conifers.

The charm and the beauty of Dropmore undoubtedly lies in the surroundings of the countryside. The magnificent and stately conifers raise their heads over an unending stretch of wooded country. One receives the idea of the interminable ages with their forgotten past, and yet not wholly forgotten, as these many relics remain testifying to the grand sense of beauty which must have existed in bygone days.

The estate is famous first and foremost for the giant cedars which rear their tall crowns and seem to crush out and suppress their less fortunate neighbours by casting around them a dense shade. Three species are to be found. The first, the Cedar of Lebanon (Cedrus Libani), one can recognise by its intense dark foliage and blackish bark. The Atlas Cedar (C. atlantica) and its close ally, the Deodar (C. Deodara), with their lighter coloured foliage and dark greyish smooth bark which later becomes fissured, form a picturesque sight. Most of them were planted about 1840, and show a remarkably fine growth reaching to 70ft., and bearing numerous spreading horizontal branches which in many cases are weighed down by countless upright unripe cones resembling miniature beehives. These trees, both young and old, are scattered throughout the whole estate and there is no mistaking their habit and characteristics.

On walking along one of the main drives, one is presented on the right hand by a handsome specimen of the Colorado Douglas fir (Pseudotsuga Douglasii). It is the finest Douglas, and also one of the finest trees on the estate. Planted probably about 1845, it is now about 85ft. in height with a spread at the base of 20yds. Its whorled branches have a pendulous appearance owing to the enormous weight of the dark glaucous foliage.

In contrast to the stateliness and dignity of the Douglas, one finds a small tree, from 20ft. to 25ft. high, of Torreya californica. This is an uncommon tree in England. It is another representative from North America, its common name being the Californian Nutmeg. The tree is shapely and of a pleasing colour, with its greyish-brown bark and slightly pendulous branches bearing linear yellowish-green leaves. This specimen is probably about forty years old and appears to enjoy the conditions at Dropmore. Farther along the drive two giant "Silvers" call forth words of praise from the visitor. They appear to be twins on a superficial glance, but on closer examination one notes the specific difference, designating one as Abies Pinsapo, with its spreading branches covered with radially arranged leaves, while the other is the Grecian silver fir, A. cephalonica. They are from 70ft. to 75ft. in height and present a noble appearance with their tall, erect stems.

A MAGNIFICENT SPECIMEN OF PINUS INSIGNIS.

Bearing away to the left from the drive down towards the lake, one becomes lost in a maze of North American thuyas, pines, cypresses, spruces and cedars. A fine, well proportioned specimen of Thuya gigantea, 65ft. in height and about sixty years of age is to be found at the lake edge in company with one of the giant redwoods of California, Sequoia sempervirens, still farther round the edge a deciduous cypress (Taxodium distichum) comes into view, characterised by its twisted bark.

On leaving the lake one wanders along many paths hedged by bushy rhododendrons. Unfortunately, there will, in all probability, be a dearth of flower this year. Here they are allowed free play and in late spring with their trusses of handsome and gaily decorative blooms spreading here and there throughout the woods and forming a dense under-cover and carpet, they should present a pleasant picture to the eye.

Other paths are lined along their sides with cedars, C. atlantica glauca and a few specimens of Picea Smithiana with their tall erect stems 70ft. high, and pendulous branches bearing their long pointed green needles. At the end of this path a glorious sight meets the eye. If we were in the eighteenth century, verses would certainly pour forth in description of a truly magnificent representative of Pinus insignis from North America.

Digitized by Google

The Monterey pine (P. insignis or radiata) rears its crown heavenwards. It commands a wide space and is more or less isolated. The pyramidal outlines which are seen in younger trees of this species throughout the estate give way in this case to a wide sweeping crown made up of stout branches with numerous dense blackish-green needles. The whole appearance of the foliage at a distance is that of the richest velvet. The stems and branches are tinged with a coppery red. What a strange fascination such an isolated pine has for one. Were this the only tree on Dropmore, it would be worth a visit.

A CORNER OF THE LAKE WITH A GIGANTIC CEDAR IN THE BACKGROUND.

Another section is devoted to conifers from Japan. Many Cryptomerias are to be found (C. japonica). On looking across from Dropmore to Windsor Castle and Ascot Downs, one especially fine specimen is to be noticed in a hollow. A low form, with pendulous branches and longer leaves which turn bronze red in autumn is especially graceful nestling as it does beneath a giant Deodar at the side of a pool. Many forms and varieties of cupressus and chamæcyparis should be noted, their golden tints showing up in striking contrast to the deep glaucous foliage of the silvers, cedars and pines.

One leaves the estate with a feeling of having acquired a vast store of knowledge with regard to the number of coniferous trees which are to be found in our country to-day. One begins to realise the myriad differences and variations which crop up within a single genus of the Gymnosperms, and how these specific variations all appear to dovetail into some prearranged plan, resulting in the stretches of picturesque woodland which beautify the countryside of these islands. The question of adaptation to environmental conditions is one which appears to be solved at Dropmore as all the conifers, without exception, seem to be thriving. In fact many of them appear to prefer conditions in this country to that of their native *habitat*, if one can judge from their majestic and healthy appearance.

A HANDSOME DOUGLAS FIR (PSEUDOTSUGA DOUGLASII).

ABIES CEPHALONICA AND A. PINSAPO.

POTATOES FOR EXHIBITION

HOW TO GROW AND HOW TO SHOW THEM.

POTATO-GROWING for exhibition is becoming daily more popular, and the present writer, as a judge at horticultural shows has more than once during the past few years had 250 plates of potatoes to judge, even in quite small exhibitions. Unfortunately, many of these plates were easily weeded out, being of poor or indifferent quality, and it is in the hope of helping growers to produce really first-class tubers that these few notes are penned.

Much depends, first, on the selection of varieties, and although such selection is influenced to some extent by local conditions, the following three may be relied upon, and should thus be widely grown:

Early Immune: Edzell Blue.

Mid-season Immune: Great Scot.

Maincrop Immune: White City.

Where the schedule provides that potatoes of a special shape must be exhibited, the following selections will be found useful, although, of course, there are many other valuable varieties:

White Kidney: New Guardian and Sharpe's Express,

White Round: Crofter and Windsor Castle,

Coloured Kidney: Prizetaker and King Edward VII.

Coloured Round: The Rector and Kerr's Pink.

Too great importance cannot be placed upon the thorough preparation of the soil. The potato always likes a light, friable soil, and this is absolutely essential if exhibition tubers are to be produced. On ordinary loams there should be very little difficulty about this, as it is only a matter of working the ground freely shortly before planting. In the case of the stronger soils, heavy clays and very stony land, special preparation will be required, and it generally pays the grower to dig out trenches, putting a layer of manure at the bottom of these and covering it over with not less than 8ins. of fine old potting soil to which plenty of burnt wood ashes have been added. A little of the potato fertiliser to be mentioned directly can be scattered over the surface and lightly forked in.

Reverting now to the average garden soil, best results are obtained by manuring almost immediately before planting. Old hotbed manure or well rotted vegetable refuse should be worked in at the rate of at least a large forkful per two square feet, the potato being a hungry subject. Lime must not be used, as it is very apt to cause scab, which, of course, renders the tubers entirely unfit for the show bench. Chalk or ground limestone can, however, be applied where it is known that the land is deficient in lime, as neither of these materials will scab the tubers. As regards preventing ordinary land scab, I have found flour of sulphur to be useful, and it should be scattered lightly over the ground at the rate of about an ounce per square yard and forked in. Where, however, the land is known invariably to produce scabby potatoes, it will be necessary to plant the tubers in holes 2ft. apart, filled with half-rotted leaves or rather dry manure from the roads, for a few years. If this is done they will be found to come up perfectly clean.

Corky Scab is another malady which is far from uncommon, and it is necessary to take steps to prevent it attacking tubers intended for exhibition. There are various ways of doing this, one of the most reliable being to dip the seed sets in dilute formaldehyde solution before planting. About a quarter of a pint of the concentrated liquid is dissolved in 7 gallons of soft water and the tubers are immersed in this from one to two hours, after which they are taken out and allowed to dry thoroughly before being planted in rows 2ft. apart, planting being completed by the end of May.

The following fertiliser will be found very valuable for producing exhibition potatoes, and 2 oz. per square yard or even rather more can be used at planting time, a similar amount being applied before any earthing-up is done:

Sulphate of potash ..	1lb.
Superphosphate of lime..	1lb.
Sulphate of ammonia ..	½lb.

I need not, I am sure, remind readers of the importance of carrying out the usual cultural operations, such as stirring the soil between the rows, thinning the growths both before and after planting, generously earthing-up the rows, and spraying with Burgundy mixture or some other similar preparation to protect the plants from blight or ordinary potato disease. As a judge I never, under any circumstances, award a prize to tubers affected by blight, as it is so very easy to protect the plants from it.

Just a hint or two now on staging the tubers at the show. Particular care should be taken that the number of specimens agrees with that provided by the schedule, and that each group is of one variety only. The tubers should be carefully lifted with a large fork and washed with warm soft water, a sponge or soft rag being used to move the adhering soil. After this a further washing will be desirable, and milk to which a little soft soap has been added should be used, as this strengthens the skin much more than is commonly recognised. Finally, it will be well to take a very soft piece of rag and dip it in one of the patent furniture creams, rubbing the tuber all over with this, and then immediately rubbing off with another soft piece of cloth. On no account attempt artificial faking of tubers, such as painting in red eyes on white kidney varieties, as any judge who knows his job is certain to spot such work and will promptly disqualify the exhibitor. The potatoes should be staged at the latest possible moment if the show is a two-days affair, as otherwise they may become green before the exhibition is over.

E. T. ELLIS.

THE NEW VIOLAS

THE following are the choicest of the viola novelties for 1924. The name in parentheses is that of the raiser, where two names appear the first is the raiser and the second the introducer.

AGNES BROWN (Stevenson).—A variety of somewhat similar colour to Annie Hamilton, side and bottom petals glossy black and top petals light lavender. It has a glistening appearance. Mr. Andrew Stevenson tells me that, unfortunately, he has lost a lot of the stock of this variety during the winter, so that it will not be available in quantity till the autumn.

DAVID STEWART, JR. (Stewart—Penman).—A purple self of smooth texture, good size and shape.

ELETHEA (Woolman).—Mr. Tooby Desmond has a new variety of this name, and I believe that it is the one Mr. Woolman lists. It is a pretty "sport" from Annie Hamilton.

DOROTHY WINN (Winn).—Deep yellow with a band of helio-blue toning off to a picotee-edge late in the season. A fine flower of good texture and build. It will probably be one of the leading varieties in the picotee-edged section.

GALA DAY (Woolman).—Deep yellow with neat edging of blue. One of the most distinct of the new violas and an acquisition. A seedling from Maggie Stevenson.

JACK MILNER (Milner).—Crimson with purple stripes. A very large flower with a fine under petal and a neat eye.

JAMES BLAIR (Robertson—Penman).—Rosy purple self. A large well built flower.

JEAN D. COWAN (Stevenson).—Pale chrome yellow with band of pale lavender, top petals lavender grey. A new colour break and a flower of fine form.

JEAN DRUMMOND (Robertson—Penman).—A large clear lemon-yellow of good form. A beautiful self and one of the best of its class. A good companion flower to John Adamson.

JENNY SIMPSON (Cochrane—Douglas).—A large rich lemon self of thick texture. A different type of flower from Jean Drummond.

JESSIE CAMERON (Cochrane—Douglas).—A canary self. Finely built flower of splendid texture. Strong habit.

JOAN BARRETT (Tooby Desmond).—A large flower of good substance, deep violet purple that shades out to lavender on the top petals. Mr. John Smith of Galemire, Whitehaven, lists this variety.

JOHN ADAMSON (Robertson—Penman).—A very fine orange-yellow of large size and smooth texture. One of the best new varieties and regarded by many good judges as the best of its colour. Although it is reputed to be scarce Mr. Penman assures me that he has ample stocks to meet all demands.

KATHLEEN CONDRY (Condry—Bastock).—A purple self of very large size, and said to be the best of its colour. Larger, rounder and of better quality than Milton Jumbo.

LIZZIE WILSON (Stevenson).—Bottom and side petals dark purple, top petals with lighter shading. Glossy texture, large size and fine form.

Digitized by Google

MARY J. STEVENSON (Stevenson).—White with bottom and side petals belted heliotrope and top petals flecked with heliotrope and violet. A seedling from the beautiful viola Rita Stevenson.

MARY DOUGLAS (Cochrane—Douglas).—Very large picotee-edged flower, cream, edged with mauve. Beautiful colour, good form and texture.

MAUD BELL (Bell).—Violet-carmine with small cream centre. A new colour break. Good substance. Fine for vases.

MEG SCOTT (Cochrane—Douglas).—A very useful white self of fine form and texture.

MISS BATES (Harrison and Sons).—A waxy pale yellow self of fine form and texture. It is rayless, a good grower and has a dwarf habit. Fine long stems. Good for vases.

MOSELEY SUNRISE (Bastock).—A very large yellow self. Distinct from Moseley Perfection. Rather tall habit but a good exhibition flower.

MRS. ALEX. MILLAR (Millar—Macfadyen).—White with broad band of bluish purple. Tall growth. Very large flower.

MRS. A. DURIE (Macfadyen).—White, suffused and bordered pale heliotrope, top petals dark heliotrope. Medium habit. Very large flower. Vigorous growth and thick stems.

MRS. DAVID FINLAY (McAlpine).—Crimson-purple ground, marbled and striped rose. A fine flower of good texture and a splendid under petal.

MRS. DAVID TORRANCE (McAlpine).—Cream ground with broad band of sky-blue on lower petals. Upper petals mottled sky-blue. A flower of the same type as Ronald Mason.

MRS. F. J. BELL (Bell).—Deep primrose, edged and belted with blue. A primrose coloured Mrs. J. McEwan. Rayless, of glossy texture and fine form.

MRS. H. HYNDS (Stevenson).—Mid-chrome with belt of deep lavender, top petals shaded with lavender. A seedling from Maggie Stevenson.

MRS. JOHN SCOTT (Macfadyen).—White with broad band of bluish purple. A very beautiful edged variety of dwarf habit. An improved Mrs. J. Terris.

MRS. ROBERT BEVERIDGE (Beveridge—Penman-Pye).—Soft delicate pink. A new and pretty shade. Held its colour well last season and should be very popular in England. Large size and fine form. A better top petal than Maggie Rutherford. One of the best novelties of the year.

MRS. WM. BOYES (Macfadyen).—A very large lemon yellow edged with lavender. Medium habit, very long stems. A very choice novelty. Mr. Forrest, one of the leading Scottish growers, tells me that he considers it one of the best twelve violas in cultivation.

OLIVE HARRISON (Harrison and Sons).—Pale primrose with a neat edge of sky blue on the lower petals, top petals suffused with sky blue. It is a good grower with a neat, dwarf habit. I can recommend this as a sterling new variety.

PHYLLIS BECKETT (Beckett — Milner).—Purple-blue suffused over a white ground with a carmine wire edge. A richer coloured Edith Bastock.

SHEILA MATHEWS (Mathews—Douglas).—A new colour break. Creamy-champagne, mottled and suffused with dark rosy mauve. A beautiful colour.

SHIRLEY DELIGHT (Woolman).—Cream edged with blue. Vigorous habit and long stems. Very free flowering. One of the best of its class.

SHIRLEY PURPLE (Woolman)—Dense purple. Darker than Milton Jumbo. Vigorous habit, neat eye and well built flower.

SHIRLEY YELLOW (Woolman).—A good yellow for exhibition purposes. Rather tall habit. A seedling from Mrs. Jamieson.

SNOWDRIFT (Woolman).—One of the finest white selfs of recent years. Pure colour and neat eye. Very large petals. An improved William Barr.

VIOLET BELL (Bell).—Glossy black, bottom petal tipped with lavender, top petals glossy black, feathered with lavender. Similar in form and habit to Annie Hamilton.

WHITLEY BEAUTY (Bell).—A good plum purple. Similar to Annie Hamilton except in colour.

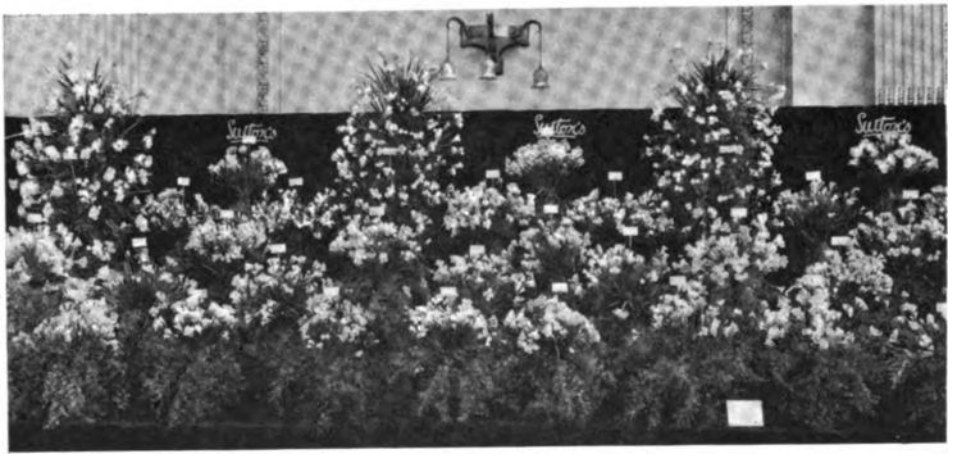
NORMAN LAMBERT.

EASTER FLOWERS AT VINCENT SQUARE

CONSIDERING the cold weather it is extraordinary how the supply and quality of the plants at Vincent Square keep to the high average. This show of April 8th was noteworthy for the high degree of excellence of the bulbs. If any criticism could be made about the Show, it was the poor variety of alpines which were shown, and this does not apply to this Show alone. After all, there are few classes of plants which can be propagated so easily as alpines; new forms and varieties are constantly coming into being as well as hundreds of new species. Yet the same saxifrages and bellis and primulas were shown which must have been seen at dozens of previous R.H.S. shows. It is not that these valuable plants should not be shown, but that some added variety might well be included. Many rock gardeners have advanced beyond the stage so obviously catered for by exhibitors at Vincent Square and we heard several expressions of disappointment that prospective customers had to go away empty handed owing to lack of variety.

The exhibits of bulbs, on the other hand, were full of novelties and unnamed seedlings. The beautiful exhibits of tulips by Messrs. Dobbie and Co, Edinburgh, and Messrs. R. H. Bath and Co., were a feature of the Show. These lent a varied touch of colour to the hall and showed what can be done with these graceful May-flowering bulbs. Among the varieties which were exhibited on Messrs. Bath's stand were La Tulipe Noire, which recalled to mind immediately that famous story of Alexandre Dumas. Unfortunately the name does not bespeak the colour, since it is more of a dark purplish hue. Ultimately, perhaps, the black colour will arrive. From the dark tints, one wandered to the warmer and more delicate hues in the pinks, yellows and reds, light mauves and purples, such varieties as Princess Elizabeth (rose pink), Avis Kennicoth, with its long oval yellow corollas, Margaret (pinkish red), Bartigon (deep red), and Blue Bird (light-mauve). How pleasing to the eye also was Messrs. Dobbie's gorgeous array of the double-flowered forms in all the colours of the rainbow. Such varieties as Tournesol, Turban Violet, Anna Roozen (a rose pink, paling towards the base of the petals and finally giving way to a light yellow), Alba Maxima (soft white), El Toreador, which lives up to its name with its red and orange hue like a toreador's cloak, Lucretia (a light pink) were included. These firms, including the Maytham Gardens, Kent, indeed deserve credit for the raising of so many of these beautiful spring flowers.

The best exhibit of daffodils was to be seen on Messrs. Barrs' stand. All the various sections were here represented—the daffodils, these narcissi with the large centre, being much in evidence. No family of plants has been more improved by hybridisation in recent years, and the results of this were shown to-day in the large number of new seedlings, which are too numerous to mention. One can find all gradations from whites to deep pure yellows. With an ever-increasing band of hybridists and co-workers the number of varieties has been so much added to that they literally seem to be without end. But yet each is distinctive in its own particular way.



MESSRS. SUTTON AND SONS' BEAUTIFUL EXHIBIT OF FREESIAS.

HYBRID FREESIAS.—Much has been done during the past few years in improving these deliciously fragrant flowers. On the present occasion Messrs. Sutton and Sons showed a vast collection of these plants. Never before have we seen such an exhibit of freesias at the R.H.S. hall. Without question it was the

Digitized by Google

premier exhibit at the Show. Here were to be seen excellent specimens of such varieties as Apogee, soft primrose yellow, darker at the tip; La France, mauve, with white throat; Monette, creamy white, suffused pink; Apple Blossom, pink, white centre; and Bluebeard, blue-mauve, brown markings on throat.

Messrs. Carter's show of cinerarias arranged in the form of a carpet was a delightful feature. Gorgeous blooms of all shades of blues, pinks and reds were massed together in perfect harmony. the whole was relieved by bowls of double tulips placed tastefully throughout the exhibit. Carter's Bouquet Blue was an especially fine variety of a deep shade of blue.

Messrs. Stuart Low Company were again to the fore with their carnations, but what struck the eye most were the acacias with their small clusters of yellow flowers intermingling with the light green of the foliage. They were indeed handsome mimosas. The species on view were A. grandis, A. armata, and also a pendulous variety of armata. A charming shrub at this stand was Chorizema cordatum, a member of the Leguminosæ.

Among the many and varied exhibits was that of Messrs. Jarman and Co., Chard, Somerset, with a tasteful array of pelargoniums and violas. The pelargoniums were a novelty and worthy of attention. Owing to the many sections of this genus in cultivation they form a most extensive class and are also among the most useful of greenhouse plants. Many beautiful varieties were on view the best of which in our opinion were the following. Maxim Kovalesky, of a good bushy habit, with large trusses of scarlet yellow flowers. St. Louis, with immense flowers of vivid scarlet-crimson with a bold white eye. Dublin, with bold flowers of a rosy magenta shade and a splendid dwarf habit. The whole exhibit was indeed distinct and attractive.

Dahlias were to the front in the capable hands of Messrs. J. Cheal and Son, who had a collection of Mignon plants which are extremely useful for bedding-out purposes. Included in their collection were chionodoxas, aubrietias, and various saxifrages. A very picturesque little group of the famous "Gaygarden" St. Brigid anemones, with their cup-shaped double blooms, each varying from three to four inches across, was shown by Messrs. Reamsbottom and Co., Middlesex. Their daring colours ranging from intense scarlet and deepest blue to the paler tints and white were such as to mark them down for a place in the garden.

Mr. Lowinsky of Tittenhurst showed some excellent plants of Rhododendron bullatum. Although growing to a bush of 4ft. it has the advantage of flowering young and is fairly hardy. It received an award of merit last year. He also showed another of Farrer's rhododendrons, R. calostrotum, a charming dwarf with grey-green foliage and large rose-purple flowers. This plant is well worth a place in the rock garden as it is perfectly hardy and of quick growth. Rhododendrons grown out-of-doors were also shown by Mr. R. J. Hanbury of Inverewe, Invernesshire. Although they had obviously suffered from the long journey, yet they showed clearly what can be grown in this mild climate of the West of Scotland.

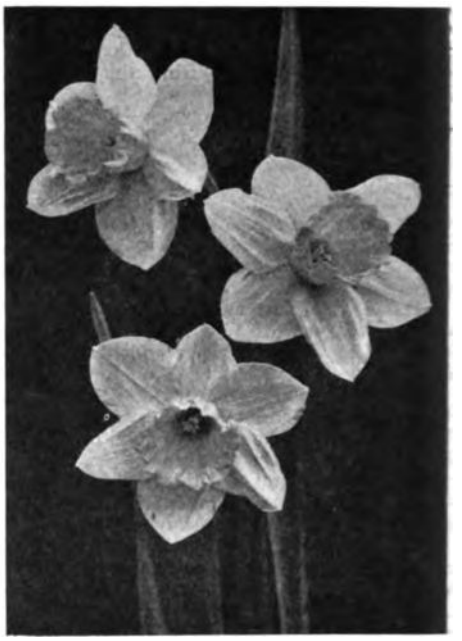
The following exhibits were also to be noted at the Show.

Messrs. Skelton and Kirby with alpines and shrubs. A dainty little plant of Viola gracilis lutea Firbright var. was also exhibited.

Messrs. Wm. Cutbush and Son with azaleas and alpines, etc.

Messrs. L. R. Russell, Limited, Richmond, with azalea species and various species of clematis.

Messrs. Pulham and Son with a collection of dwarf shrubs and ericas.



A GRACEFUL DAFFODIL, NARCISSUS FORTUNE.

Awarded a first-class certificate.

Messrs. W. H. Rogers and Son, Limited Southampton, with primulas, cupressus, andromedas, etc.

Messrs. Maxwell and Beale with aubrietias, omphalodes, myosotis, anemones and hepaticas.

Messrs. Ladham's, Limited, Southampton, with violas, omphalodes, double-flowered forms of Caltha palustris.

Messrs. Geo. Whitelegg with alpines and shrubs, and also a bush of Rhododendron Pink Pearl.

Messrs. Bakers of Wolverhampton with Primulas Wanda and denticulata, andromedas, etc.

Messrs. R. Tucker and Sons, Oxted, with a collection of alpines.

Messrs. G. H. Waterer, also with an array of alpines.

Mr. Clarence Elliott with well grown Saxifraga Griesbachii Wisley var., and graceful plants of Sisyrinchium grandiflorum.

Messrs. Carter Page and Co., Limited, with alpines, violas and dwarf shrubs.

Messrs. Geo. Bunyard, Maidstone, with their usual fine collection of apple varieties.

Messrs. Dicksons, Hawlmark, Belfast, with poppy anemones, giant hybrids.

Miss Hopkins with a tasteful collection of polyanthus.

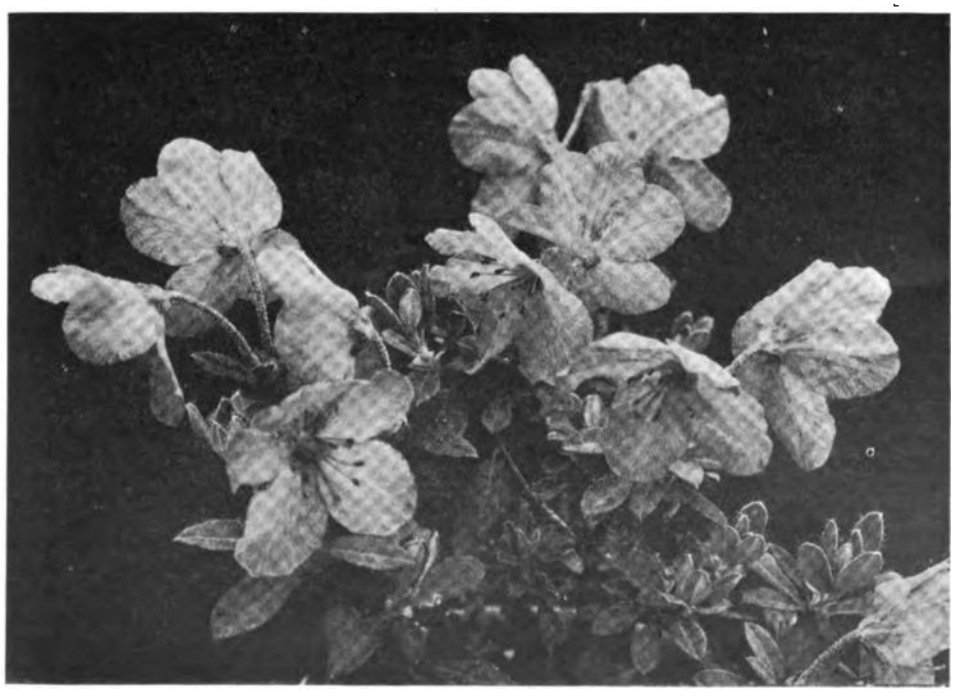
Mr. J. J. Kettle and Mr. B. Pinney, Blandford, with violets.

Mr. F. G. Wood with pulmonarias, cytisus, Pemberton roses, etc.

Mr. James Douglas, with auriculas.

Mr. G. Reuthe with rhododendrons, andromedas and other shrubs.

Messrs. Allwoods and G. Engelmann again had their stands tastefully decorated with their charming perpetual-flowering carnations of every hue and shade, which focussed the attention of all present. Such fine varieties as Edward Allwood, White Pearl, Mary Allwood and Sunshine were again brought to the notice of the horticultural enthusiasts



RHODODENDRON CALOSTROTUM, A CHARMING DWARF WITH GREY-GREEN FOLIAGE AND ROSY-PURPLE FLOWERS.

Digitized by Google

as at the British Carnation Society's Annual show three weeks ago.

NEW AND RARE PLANTS.

NARCISSUS FORTUNE.—A fine daffodil borne on stiff, wiry stems. The flowers are of good size, deep yellow in colour with orange centre. First class certificate. Shown by Messrs. Walter T. Ware, Limited, Bath.

ARCTERICA NANA = Andromeda nana.—A dwarf-growing shrub from Japan with typical foliage and small bells of a dingy white. Although not particularly striking as a single plant, it should be of use in the rock garden. Its greatest advantage is its strong scent of honey which is not so sweet as to be sickly. Award of merit. Shown by Mr. G. Reuthe.

PROSTANTHERA ROTUNDIFOLIA. — A handsome shrub about 4ft. high with a mass of tiny flowers of a shade of pinkish-purple hanging in short terminal racemes and which stand out in bold relief to the light green of the broadly ovate leaves. The plant is a member of the Labiatæ with resinous glands and strongly scented. The flower is uncommon, the anthers being prominent and spurred. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

ELDORA.—A beautiful fancy variety of a perpetual flowering carnation. In colour, it is clear white at the base, which gives way to rose pink edges. The blooms are exceptionally well formed, are fragrant and freely produced. Award of merit. Shown by Messrs. Allwood Bros.

VIOLET PRINCESS MARY.—A delicate and graceful little plant of a deep purple shade and exceptionally fragrant. Award of merit. Shown by Mr. J. J. Kettle.

RHODODENDRON PROSTIGIATUM. — A dwarf rhododendron, a cross between R. prostratum and R. fastigiatum. The growth is very vigorous while the flowers are open campanulate and large for the size of the plant. The colour is violet. Award of merit. Shown by Mr. E. J. P. Mayer.

ORCHIDS

AWARDS OF MERIT.

LÆLIO-CATTLEYA ORANGE BLOSSOM VAR. JUNE (L.-C. Elinor × L.-C. Trimyra), from Lieut-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos. A beautiful hybrid, the well developed plant carried three spikes, each bearing three flowers of medium size, in colour bright orange-yellow, tinged with gold, equally suffused throughout all the segments.

ODONTOGLOSSUM DUKE OF YORK (percultum × illustrissimum), from Mr. R. Gerrish, Milford Manor, Salisbury. A distinct advance towards the desired "blue-tinted" odontoglossum. In this example the roundly formed flowers were blotched with violet-rose in which a bluish tinge was clearly visible.

WILSONARA WENDY VAR. CARDINAL (Odontoglossum Lambeauianum × Oncidioda Cooksoniæ), from Messrs. Charlesworth and Co. An interesting hybrid composed of the three genera odontoglossum, oncidium and cochlioda. The erect spike bore fourteen large flowers of rich cardinal red evenly suffused through the segments.

ORCHIS PAPILIONACEA, from Major Albert Pam, Wormley, Bury, Broxbourne. Several examples of this species of terrestrial habit were shown growing in a shallow pan. The expansive labellum is prettily marked with lines and spots of deep mauve colour.

ODONTOGLOSSUM CRISPUM VAR. MARY GRATRIX, from Messrs. Sanders. A fine example of the Pacho type of imported crispum, the flowers having broadly developed segments, white, except for a few small spots on the labellum.

CYMBIDIUM CONINGSBYANUM VAR. MAMMOTH (grandiflorum × insigne), from Messrs. Sanders. A splendid result in which the tall spike bore eighteen unusually large flowers, cream coloured, the sepals tinged with rose pink, the openly displayed labellum prettily marked with numerous small spots.

CULTURAL COMMENDATION.

To Messrs. Sanders for the above-mentioned plant of Cymbidium Coningsbyanum, which exhibited an excellent condition of high cultivation.

To Mr. F. Streeter, gardener to Major Albert Pam, for Ophrys lutea, or closely allied species, of which several robust flowering plants were exhibited together in a shallow pan.

Several excellent groups were staged, the finest being that of Messrs. Sanders, and to which a gold medal was awarded; Sir Jeremiah Colman, Bart., Gatton Park, Surrey, and Mr. H. T. Pitt, Stamford Hill, both received silver-gilt Banksian medals for finely cultivated species and hybrids.

ANSWERS TO CORRESPONDENTS

TREES AND SHRUBS.

Camellias and Stuartia (C. J.).—Camellia Sasanqua can be grown in a cold greenhouse with the different varieties of C. japonica. As it is a less vigorous bush, it ought to be given a position where it will not be crowded by stronger plants. There are several varieties of C. Sasanqua, some with white, others with red or rose, and others, again, with double flowers. In Guernsey it ought to grow quite well outdoors with other camellias. Stuartia Pseudo-camellia ought not to be planted indoors, for it gives good results in outdoor borders and may be expected to blossom better outdoors than under glass. Plant it in well drained loamy soil containing a little peat or leaf-mould, and do not disturb it once it has become established.

Hornbeam Hedge (M. C.).—It depends on the type of plant whether pruning is required. If nicely furnished to the ground with twiggy branches, all that need be done is to take off the top or leading growth to encourage the development of a closely grown hedge. Should the small plants be thin young trees, pruning of the side branches and top will be desirable.
